Mr. G. Findlay Shirras, M.A. (Director of Statistics with the Government of India), speaking for himself and for the other visitors, said they had been much interested in Sir William Meyer's admirable paper. The linking of the rupee to gold was a very great boon, and it was thoroughly appreciated by those who had watched the development of Indian currency during the last few years. He entirely agreed with the Chairman that everything that had been done by the various Currency Commissions had been done with a single eye to Indian interests. At the present time the gold sovereign was at a premium of 29 per cent. as compared with the paper pound, and the policy of linking the rupee to gold instead of to the pound sterling had many advantages, which were referred to in the Report of Sir Henry Babington Smith's Commission. India had a favourable balance of trade, and it was therefore a very great advantage for her currency to be linked to gold. In regard to that and to the fixing of a high exchange, it must be remembered that the question of preventing a high rise in prices in India was very important indeed, although unfortunately it was not realised by everybody. With regard to what Mr. Moreton Frewen had said, he thought he was speaking from the Indian standpoint when he said they totally disagreed with him. India was entitled, as the Commission had said, to a share in the world's metals, and was entitled to take what she required in the form in which she required it. It was a great satisfaction to them to find that the Indian Mint, a branch of the Royal Mint, was to be opened, because at the present time in India sentiment counted for a very great deal, and the opening of that mint appealed to their national pride. The Commission had also approved of the sale of gold in India, and it was a matter for consideration whether the sales could not be made through the banks and their branches, and perhaps through selected treasuries, in amounts of 20 to 25 tolas in order to get at the middle-classes, who had to buy gold for marriage and other quasi-religious purposes. Next in regard to the question of inconvertibility, to which Sir William had referred, the Government of India at that time—he spoke as an outsider, not being in the department affected—only regarded the question as one of passing expediency which would not last for any length of time. Luckily it was avoided, and he thought they all agreed that in a country like India it had to be avoided if it was possible to do so; but at that time there seemed to be no other way out of the difficulty. It was only to be temporary and only to be introduced as a last result. As he had pointed out in his recent book, "Indian Finance and Banking," he was not in favour of the proposal, but he thought that Sir William Meyer had not quite put the viewpoint of the Government of India altogether fairly. He could speak of Sir William Meyer's work in India from a detached point of view, as he had not had the pleasure of his personal friendship; but he had long felt that Sir William was a good man to go tiger-hunting with. He had started his career nearly forty years ago, when he (the speaker) was in what was popularly known as the nursery; he had given his whole services to the interests of India, and in spite of domestic afflictions had held on to his post during the war, when they had felt in India that the existence of the Empire was at stake and it was their duty to rally to its defence. They realised how much Sir William had done for India; that he had done far more than was generally recognised. He could tell some stories—but he dared not do so—of the work Sir William had done, of how he had fought India's battles and safeguarded her expenditure. They appreciated to the full all that Sir William had done, and hoped that he would look back on the trials through which he had passed with pride and with the greatest possible satisfaction.

Mr. Gershom Stewart, M.P., said that although he did not entirely agree with all Sir William

Meyer had said, he had listened to the paper with profound interest. He sympathised, to a certain extent, with his old friend, Mr. Moreton Frewen, and regretted that India had taken gold so closely to her bosom. The Chairman had stated that he had been associated with four commissions enquiring into Indian currency. It had occurred to him, when he heard that remark, that the constitution of the Indian currency system must be a little rickety, if four commissions were required within twenty-seven years to consider it. He was in China when the Indian mints were closed to silver, and he would have much preferred leaving those eight hundred millions of people—three or four hundred millions in India, and about the same number in China—to go on with the one metal which had sufficed them for centuries. The boycott of silver brought about a panic amongst salaried officials. Men saw their salaries, when paid in rupees, decreasing in value, but he thought it would have been better if they had been given an exchange allowance, and their minds relieved in that way. At the time when the Indian mints were closed he happened to be in New York, and he had asked the manager of the Hong Kong Bank at New York what was the price of silver. He replied: "It has got no price." He thought that answer was rather "up against" the action that India had taken against silver. He had been engaged in what he might term a lone fight in the House of Commons for the past fortnight, protesting against the depreciation of the coinage of this country and of the African Colonies. One thing in the report of the recent Currency Commission which appealed to him more than any other was that they had had the wisdom to say they would not debase the rupee in India, and that they would not haul down the flag because of temporary trouble in the silver market. Since that Commission had reported, the price of silver had gone down considerably. The Government were to be congratulated in maintaining the rupee as a pure coin, and he hoped the same principle would be maintained throughout the Empire; honest money was the best.

Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I. (Chairman of the Indian Section Committee), said he desired to convey to Lord Chalmers the cordial thanks of the Royal Society of Arts for his kindness in coming to preside at the meeting. He also wished to propose an equally hearty vote of thanks to Sir William Meyer for the extremely interesting and able paper which he had read.

Mr. J. A. Toomey (National Bank of India) said it afforded him much pleasure to second the resolution. Sir William Meyer had given them a most interesting paper, as was to be expected from such a high authority. The business world, to which he (the speaker) belonged, had the highest regard for the courage and ability Sir William had displayed throughout his term of office in India.

The vote of thanks was carried unanimously.

Sir William Meyer, in reply, thanked the Chairman and those who had taken part in the discussion for their kind remarks. There were not many criticisms for him to meet. His friend Mr. Moreton Frewen still remained of the opinion that, in the classic words of Mr. Bryan, India "should not be crucified on a cross of gold." He did not wish to enter into a discussion on that, because the change was made nearly thirty years ago. Events had moved rapidly since that time, and even if they wished to do so he did not think they could restore the old order of things. He would remind Mr. Frewen that four impartial Committees had maintained that the closing of the mints was a sound and necessary step, and secondly that gold came into India even when the mints were free. The finances of the Government of India were so embarrassed by the fall in the value of the rupee in 1893 that if some measures had not been taken to deal with it extra taxation would have been necessary. Mr. George Miller had asked why the Government should go on selling reverse councils on more favourable terms than the banks could offer. So long as there was an exchange in which the Government had to intervene, the Government had to do its best to keep it up. If a crisis occurred in the exchange, the very fact that the Government showed its support by selling reverse councils tended to establish stability, which was the prime object they had in view in instituting reverse councils. It was rather like what he had noticed as a humble private individual since he had come back to England; when the British Government took certain steps under D.O.R.A. at once people said that prices were going up because of Government control, and urged that that control should be removed. As soon as the Government did this prices went up still higher, and then people immediately said, "Why on earth did you relax your control?"

The meeting then terminated.

SIXTEENTH ORDINARY MEETING.

Wednesday, April 14th; Sir Herbert Morgan, K.B.E., in the chair.

The paper read was—

THE FUNDAMENTAL BASIS OF GOOD PRINTING.

By Joseph Thorp,

Member of Council, Design and Industries Association.

Good printing—what do I mean here by "good"? The word might have been chosen deliberately to focus attention on the mechanical side of printing and refer to merely technical efficiency—good inking and even impression; whereas I wish to refer more particularly to

the design of printing, what might be called the æsthetic or "artistic" side. But that last word at least has been too often profaned for me to profane it further.

My main thesis is that in printing, as in all the practical or applied arts, the æsthetic and practical aspects cannot be separated. "Fitness-for-purpose" is the test. Here is to be found the fundamental basis. Made things are not artistic if they don't "do their job," if the ornamentation is something added or stuck on, not flowing out of the nature of the material and the practical purpose of the plan. This is the thesis of the Design and Industries Association; it was admirably stated (and occasionally in practice denied) by William Morris; it has been brilliantly re-stated by Professor Lethaby (*e.g.* "A work of art is a well-made thing, that is all." "Art is not a special sauce applied to ordinary cooking. It's the cooking itself if it is good"—words which I should like to see engraved on the portals of every Art and Craft school in the country).

The Forth Bridge, depending for its appearance on the due balance of thrusts and tensions in the material chosen (steel), is a truer and therefore more beautiful thing than the Tower Bridge, which was consciously "decorated" to make it "artistic." The modern motor-car, as developed from the first clumsy horseless broughams along the lines of the engineering solution of its practical problems—speed, wind-resistance, stability, etc.—is certainly a more beautiful thing than it would have been if Professor Herkomer's appalling suggestion of fitting those same mechanical broughams with prows in shape of swans had been followed. Battleships, aeroplanes, weapons, tools, implements of sport—these develop their own form of beauty (or, not to claim too much, avoid falseness which is ugliness) by sticking to the lines of fitness-for-purpose. Architecture and furniture-making likewise. I am afraid tailoring and dressmaking follow another rule, dictated by vanities and interests rather than principles, or women would never have worn crinolines or hobbles, and certainly men would never have encased themselves in the Victorian (and so far as one can see) Eternal *Cul(otte)-de-Sac* of Trousers.

Good printing, then, is primarily printing that does its job. Legibility is its first requirement. Persuasiveness one might state as its second—to include comeliness and appropriateness. That is to say, a printed thing must first be able to be read. And read easily, pleasantly; therefore we add the "persuasiveness" of comely, appropriate design. Tradesmen selling goods by advertisements have realised this truth. But if you consider the matter, nearly all printing is advertisement in the sense that it announces something which the announcer wants read. Refusal to understand this abject platitude accounts for much squalid and careless printing. If I am told that good printing is expensive, the general lines of my answer are: first, that bad printing that isn't read is dear and wasteful at any price; second, that a good deal of what goes to make good printing is not a question of cost at all, but of knowledge and care.

Legibility, then, is our first desideratum. We must begin with a legible *letter*. We want to find the most legible type of letter within the limits of the forms of the traditional alphabet—in our case the Roman capitals and small letters with their Italic. And here we must distinguish between the *absolutely* most legible and the *practically* most legible. It is obvious that if we were designing an ideal alphabet to-day—an absurd supposition anyway, as all practical arts are gradual evolutions in which tradition plays a greater part than originality—we should avoid such similarities as are involved in these groups: CGOQD; PRB; EFB; eco; il; mnu; bh. There are too many coincident parts of these letters to ensure perfect legibility. But the alphabet as we have it is an established code. The difficulties of introducing an ideal letter are now insuperable—though we have got rid of the long s—ſ. We have to keep the essential forms as we now have them; and we don't want "original" or "fancy" letters to interfere with the rapid-signalling of the sound which is the function of a letter. A triumphantly beautiful form of Roman capital survives in the incised inscriptions of the Trajan column. As to the smaller or lowercase letters, the art of printing came happily at a time when the art of writing was at a noble, not a debased, period, and the early printers had the most superb models both for their letters and for the arrangement of their books. One notes in passing how the new art leant on the old in the first period of its development.

It is extremely comforting to those of us who prefer the old-style and old-face letter, with its freer drawing, its broader forms, and, as we judge, better distribution of thick and thin, to the "modern" face with its fine hair lines, its too starkly contrasted thicks and thins, its tendency to compression, its mechanical pre-

cision, to know that the old style and old face is demonstrably by laboratory tests the more legible. A notable gain in legibility readily appreciable by even the uninstructed eye is in the old-face figures with their ascenders and descenders 123456789 as contrasted with 123456789, where particularly the 3 and 8, and often the 3, 8, and 9, are easily misread, especially in small sizes, or if at all battered or weak in impression.

Having chosen a legible letter we must then aim at a legible combination of letters. The design of a printed page is in simplest essence the arranging of a panel of black (or, in fact, grey) on a white (or light) paper. The white spaces left—margins, etc.—are an essential factor of legibility, as they are an essential part of the design. Margins equal and sufficient (that is sufficient to rest the eye) all round would serve our fitness-for-purpose test, but to achieve comeliness, we, if we are wise, so arrange our panel that our tail (foot or bottom) margin is appreciably greater than the others. If we are designing a book we assume the double opening of two pages to be the unit of design and arrange our double page so that the head margin is smaller than the middle (or gutter) and two foredge (side) margins (these three are equal); the tail margin we make largest of all. Let us accept this standard from the finest practice and then seek practical reasons for it. First, if a panel be so put on the page that head and tail margins are equal, it does, in fact, by an optical illusion, look as if the tail margin were smaller. Secondly, the book is held by the thumbs, by the tail margin. We need, then, thumb-room. There is probably also some demand of the eye derived from a common principle in architecture that the building needs a sufficient "base" to look (and generally to be) right.

Amplitude of margins is a matter for individual decision, depending on size and weight of type, limitations, etc. The ample wide margins of the earlier printed books were possibly designed to admit of annotations by the reader according to the practice of the period. If so, they might reasonably be reduced in modern days. One has seen books published in two editions, ordinary and *de luxe*, where "*de luxe*" merely means that the edition has over-ample margins surrounding the same sized panel of type. This is not "art" but folly or pretentiousness—a small oasis of dwarfed type in a waste of white paper.

A very important point to determine is the length of line in proportion to the size of type. It must not be so long that the eye needs a deliberate effort to pick up the beginning of each line, an effort which is increased as the size of type decreases. It has also to be remembered that the plane of a page being flat the eye is theoretically in perfect focus (if the reader keeps his head steady) only at one point of the line (say the centre), and is at all other points of the line out of focus to a greater or less degree according as the line is longer or shorter. I consider 4½ in. to be quite long enough for 14 point type; 4⅜ for 12 point; 3⅞ for 11 point; 3⅛ for 10 point; 2½ for 8 point. These measurements are approximate, empirical, and perhaps a little arbitrary. It is a very common thing to see these measurements almost doubled. I am a strong advocate, on both æsthetic and practical (including economical) grounds, of the revival of the double-column page. Cost of paper is inducing publishers to use smaller type without cutting the size of the customary page. This means "bad" printing.

The use of ornament needs careful restraint. When in doubt omit. When not in doubt try to get in doubt. As a first step to right use of ornament cultivate an ascetic severity. Some printers can never resist filling up odd spaces of white with bits of "ornament," rules, etc. Advertisers have long been driven by competition to recognise the value of white space for emphasis, of simplicity as against complexity. This teaching is perhaps negative rather than constructive, designed rather to avoid ugliness than to create positive beauty. Yet orderliness, due proportion, fitness for purpose, right use of material, avoidance of fakements—all this means positive beauty in the practical arts.

DISCUSSION.

THE CHAIRMAN (Sir Herbert Morgan, K.B.E.), in opening the discussion, said he was sure everyone present appreciated the author's eloquence and activity. If the world were filled with the kind of printing that the author had so much at heart he thought it would be a far finer place, but it was necessary to consider how far it was possible for the author to realise his ideals. He had said that he "put over" the fact that good printing meant fitness for purpose, and personally he thought the author might congratulate himself on the fact that he did "put it over." It was in his opinion an extremely able definition of good printing, but he would like to ask the author who was to judge as to the purpose, and whether he

would give a little more illumination on the subject of the purpose. Broadly speaking, printing was produced either to be sold—in which case he took it the purpose was to sell as much of it as possible—or to convey knowledge and information. With regard to the printing that was produced to be sold, probably those responsible for its production would say—by taking certain perhaps grave liberties with the ideals set forth by the author—that that book would be the most successful which would "take on" with the public, and in that way it would achieve fitness for purpose. With regard to printing used to convey knowledge and information, so many people wanted their own information conveyed and their own knowledge spread that a strong competition of method was the result. He was afraid that the author's ideals were a little too severe and restricted to find favour with those people who produced books in order to sell them, and in the same way those who were competing for the education of the people found it necessary deliberately to depart from the rules and regulations that the author had drawn up. Was it possible that they could achieve their fitness for purpose and at the same time produce the good printing which the author had so much at heart? One other thought had occurred to him in connection with the paper, namely, that in considering fitness for purpose in printing he felt much more might be done to link up good printing with the architecture of our streets and buildings. The capacity of all good printed notices or even the humble lettered sign in the shop window to illuminate a dull and drab thoroughfare and to elevate public taste was, in his opinion, very great indeed, but in that respect also he felt one would have to take certain liberties with the author's very strict views.

Mr. J. R. Riddell (Principal, St. Bride's Institute) said the paper had been illuminating and interesting, and at the same time humorous, but personally he thought it would have been better if the author had spent the first twenty minutes of his time in giving his own views on good printing rather than in dilating on the inartistic forms of rustic arches, motor cars, hammers, trousers, crinolines, etc. Like the Chairman, he would very much like to hear what the author had to say about fitness for purpose. In dealing with type faces, the author was on safe ground when he stated that the first principle of a good letter was its legibility, but who was to determine which was the best letter? Everyone had different views as to the form that the ideal letter should take, and therefore it was not advisable for any person, or groups of persons, to set up as a standard a particular form of letter and say that that was the only correct form for the letter to take. The author certainly made a happy hit by the phrase "fitness for purpose," but again, who was to determine the correct interpretation of the fitness for purpose of a particular style or letter in a piece of printing? No self-respecting printer would set up a milliner's advertisement in the same type that he would use for an undertaker's announcement, but within those two extremes there was a wide field for individual expression by the use of type. It had to be recognised that, no matter what one's personal ideals might be, or how much some printers would like to see a simple style of printing, it was the man who paid the bill who called the tune, and really it was the customer who needed educating to the fitness for purpose. A great deal could be done by enthusiastic printer-craftsmen and persuasive printers' salesmen in educating the buyer of printing, and thereby helping to place the art on a sound foundation; but, after all, printing was a commercial proposition, and the customer demanded, and usually obtained from his printer, the style that he considered best suited to his particular needs. The author referred to the work of William Morris, and gently hinted that it left something to be desired. Personally, although he took second place to none in his admiration for some of the works of Morris, he did not hesitate to go further than the author and to say that it would be well for Morrisian disciples to recognise that their master issued some of the greatest abominations ever put forth from the printing press. Some time ago he was responsible for printing a booklet in the Morris style, on hand-made paper. He submitted the work to a Morris enthusiast, who considered it to be a fine example of printing, and expressed a wish to obtain a copy, but when it was made known to him that it had been mechanically composed and printed on a modern high-speed printing machine his keenness to obtain a copy of the work was not so apparent. That attitude, he thought, was not helpful, and it was unfair that any society or educational body should set up a certain style of work and say that that was the style which must be followed, often to the exclusion of all others. The author had referred to proportions and margins, and had shown an example of a panel of lettering placed geometrically in the centre of the page for the purpose of disproving the contention that it was necessary to raise the printed matter on a sheet a little higher than the centre so that it might have the appearance of being centred. If the author had taken a single line of type instead of a panel some two inches deep, he thought the optical delusion would have held good. It had been correctly stated that the large margins, which had been adopted from the written book, allowed for the handling of the book. He suggested that they also served another very useful purpose, in that, if the book had to be re-bound and trimmed at some future time—and most bindings gave out before the print—large margins enabled that to be done with less chance of losing the pleasing proportions of a well-printed page. With regard to the diagrams drawn by the author and his reference to printers looking upon type as "lumps of metal," he would like to remind him of a point that he,

along with numerous advertising experts, frequently lost sight of, namely, that many types had what was called a "beard," *i.e.* a blank space left on the body which must be allowed for when "laying-out." The author must certainly be complimented on his witty discourse, which, personally, he had very much enjoyed, but he was afraid the author had not thrown much light on what was "the fundamental basis of good printing." The most sincere compliment that could be paid to him was that he would undoubtedly make a better salesman than printer.

MISS A. DEANE BUTCHER said that the organisation with which she was connected wished to send half a million books and a thousand commercial travellers to Russia, and the ordinary letter "H," which consisted of two perpendicular lines with a horizontal line between them, was read by the Russians as "N." That was due to the fact that the Russian printer had degraded the type, because in the old religious literature of Russia one found that the "N" was made very nearly the same as the English "N," the only difference being that the oblique line did not come quite to the top of the letter. It was clear that it was natural to man to degrade type. The hand-made type had been gradually degraded in a way that Mr. De Vinne, who was the American authority on the subject, described as feminine. He said that all the printing that was bad, all the printing with which he disagreed, was feminine, and that all the printing which was correct was masculine. The author had said that regard must be had to fitness for purpose, and in sending books to Russia one surely ought not to print the letter "H" in such a way that it would mislead the Russians into thinking that it represented the sound "N." The same observation applied to the writing, or lower case, letters "n" and "m." The Russians pronounced the writing "n" as we do the letter "p," and the writing "m" as we do the letter "t." Common sense demanded that these lower-case letters "n" and "m" should be omitted and the small capitals "M" and "N" substituted. These were equally legible to English and Russian people. With regard to the traditional "N," the lower case "m," much difficulty had been experienced. It should not be put into a typewriter. Mechanical printing was necessary now because there were so many people in the world, and neither time nor money could be afforded to do the beautiful work which could be done by hand. But when one was dealing with an educational print, such a print as was necessary for a foreigner or for a child, surely it ought to be done for the people that were going to read it. If one was going to write for Russians one must make letters that did not mislead the Russians. All the Russian letters could be transliterated into English letters, and *vice versâ*, although in England there were now three or four different transliterations, each one of which was very confusing. A well-known Russian scholar said that could not be done, but by that he only meant that he personally could not do it. The Roman type was regarded by some people as though it came down from Heaven with the Ten Commandments, but it must be remembered that that type was made originally for the Latin language, and the English were not Latins and did not speak the Latin language, although they had a great number of Latin words. Sir Arthur Shipley, the Vice-Chancellor of Cambridge University, said in his testimonial to orthotype printing that it was very excellent, because in a very short time the word of an Englishman would not be understood in Canada nor the word of a Canadian in England, but when he was sent some specimens to give to his foreign friends he said the print was very ugly—that was to say, it was not familiar to him and therefore it was ugly. Professor Adamson, of King's College, in his book on "The Practice of Education," said: "The teaching of English reading is not an educative process." That meant that large sums of money were being spent upon teaching people by a process that was not an educative one. That was because the books were not written in an educative manner. She would like to hear from the author what the small modifications were that he would allow to be made in the Roman type. There was a method of making very small modifications in the English language so as to produce an educational print, and that was by adding to it interlinearly seven shorthand letters. When in Canada she had had some trouble by asking for "Bāliol Avenue," when the street was known locally as "Balĭol Avenue," and that was one example that showed the necessity of producing an educational print which would serve as a key to the ordinary print and would show where the emphasis in a word came.

MR. LEON GASTER agreed with the author that it was very useful to print in two columns, as it was much more convenient for the eye to travel a short distance (not exceeding about four to six inches). It was very important to study the nature of the paper on which one was printing. When a magazine with which he was connected was started he had great difficulty in obtaining a paper with a matt surface sufficiently free from gloss and yet revealing half-tone blocks satisfactorily. The difficulty had, however, been so satisfactorily overcome that in a Report of the Committee of the British Association on Schoolbooks and Eyesight, issued in 1915, that journal was placed first on the list as complying best with the required absence of glossiness. The size of the type was an aspect of the subject in which he was very much interested. He wished that printers would raise their voice against a very small print. In some of the magazines intended for children the paper, the printing and the type were such as ought not to be passed. The Bible was often produced in a type that it was extremely trying for a child to have to

read, even by a good illumination; if an opportunity presented itself to have the Bible re-cast several editions should be made with a more readable type.

The Author, in replying to the discussion, said that the difficulty with regard to a standard type to deal with the question of pronunciation was that climatic conditions would always make different pronunciations. The question was not really one of pronunciation. He merely meant that we had as a matter of fact a literature at this moment in existence, and he thought that it was not possible in the present stage of civilisation to bring about a universal change, say, of a given letter. He also wished to say—and the Chairman knew it better than anybody—that when the printing reform of which he spoke came into operation it was all along the lines of simplicity and classic asceticism that it progressed. Looking at it as it applied to posters, one wanted a poster to be seen in a very different way from such a thing as a little Christmas card, it had to be seen in a flash. That was why the colouring was simplified and the ridiculous shading up that the old lithographic artists were so fond of was eliminated.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his paper, and the meeting terminated.

POWER FROM NATURAL STEAM SPRINGS IN ITALY.

A very interesting experiment has been carried out at Larderello, in Tuscany, with extremely satisfactory results. At this point there is an area of about thirty-six square miles where, from time immemorial, natural steam springs have existed. As early as 1790 the presence of boric acid in the water condensed from the steam was detected, and for many years a company at Larderello has been producing boracic acid on a large scale. This company controls the entire district.

The natural steam was first used for evaporating the water from which the boracic acid is obtained. Wells are drilled and dry steam at a pressure of three atmospheres is found at a depth varying from 195 to 390 feet. At Larderello some of these wells have had an initial production of 154,000 pounds of steam per hour. In 1897 the natural steam was first used for heating the boilers of the company, and in 1905 a further step was taken when experiments were conducted with the steam in a piston engine. The results were so satisfactory, writes the United States Trade Commissioner at Rome, that a large engine was installed which is still in operation.

Having a very large surplus of steam in excess of that required for its own uses, the company referred to decided to utilise this excess steam for producing electric power. In 1912 a 250-kilowatt turbo-generator was installed—the natural steam being employed not directly in the turbine, but as a means of heating water for the production of the steam required; and in 1916 a large power plant, containing three units of 2,500 kilowatts each, was completed. A fourth unit will soon be added, which will give a capacity of 7,500 kilowatts, one unit being held in reserve. The boilers which are used are on the principle of the ordinary tube boiler, and consist of aluminium tubes contained in a shell of sheet iron. The natural steam at a pressure of about one atmosphere circulates outside the tubes, within which the pure steam is generated at a pressure of about one-half atmosphere. Each element is calculated to produce 13,200 pounds of pure steam per hour. The turbines, which were specially made by an Italian firm, have a maximum output of 3,000 kilowatts at 3,000 revolutions per minute—an actual net capacity of 2,000 kilowatts. Each turbine requires 77,000 pounds of steam per hour.

The principal power lines, which are at 36,000 volts, are as follows:—First, Larderello to Siena, connecting with the Valdarno system, which supplies eastern Tuscany, including Florence: second, Larderello to Leghorn; third, Larderello to Piombino, where important iron and steel works are situated; and fourth, Larderello to Massa, where there are iron and copper pyrites mines.

So far as the district of Larderello is concerned, the use of natural steam has solved the coal problem, which is such a serious one for other sections of Italy that have not been equally favoured by Nature.

PROGRESS IN TANNING FISH LEATHER.

Excellent progress in the tanning of fish leather is recorded by the United States Bureau of Fisheries, and a number of the difficulties in the way of the development of the industry have been overcome.

One company which is tanning fish skins has established a station in North Carolina and another in Florida for the capture of sharks and porpoises, and is meeting with success in its fishery for sharks. It is understood that the number of stations will be increased as rapidly as possible. Another company has recently acquired a site for a tanning establishment in Washington for the purpose of tanning the hides of sharks, beluga, hair seals, etc.

Samples of leather recently submitted to the Bureau show marked improvement in appearance over earlier samples. The leather is soft and pliable, and appears to have ample strength for many uses. Arrangements have been perfected for the Bureau of Standards to make tests of the leather products as to durability, porosity, tensile strength, pliability, water absorption, wearing qualities, etc.

The nets which the Bureau developed for the capture of sharks are proving successful, and are being adopted for the fishery. At the fishery stations the liver oil is being extracted and the flesh converted into fertiliser, so that none of the material is wasted.

NOTES ON BOOKS.

The Ancient Entrenchments and Camps of Gloucestershire. By Edward J. Burrow. Cheltenham and London: Ed. J. Burrow & Co., Ltd.

Anyone who has travelled through Gloucestershire must have been struck by the great number of ancient earthworks and entrenchments to be found there. Several of these may be traced to the period of the Roman occupation of Britain, but a large number seem to date back to 2000 B.C. or earlier. Mr. Burrow has made an attempt in the first part of this book to reconstruct the conditions of life amongst the camp-men, and has briefly traced the history of the country from the earliest days through the Roman period (he gives a striking sketch of the restoration of the Roman Villa at Chedworth) to the invasions of the Anglo-Saxons, the Danes, and the Normans.

The second part contains a series of drawings by the author of a very large number of the entrenchments and earthworks of the county, together with brief descriptions of each. These are arranged in alphabetical order. The preparation of this part must have involved a great deal of time and trouble; but the result is extremely interesting, and gives the reader a very good idea of the extraordinary wealth of archæological material to be found scattered throughout Gloucestershire.

The volume concludes with a useful map of the country, on which are indicated the sites of the principal camps and entrenchments described by the author.

GENERAL NOTES.

Sponge Gathering in Tunisian Waters.—Although the Greek divers have abandoned the sponge fisheries of the Tunisian coast for those of Tripolitan waters, unexploited since the Turko-Italian War, where, it is reported, unexcelled sponges have recently been taken, the sponge beds along the coast of Tunis are proving profitable to the Sicilian drag-nets and harpoonists now plying in the Gulf of Gabes and around the Kerkenna Islands. Sfax, the chief port of southern Tunisia, is naturally the trade centre of the industry—the sponge market of Tunisia, whence domestic and export prices are regulated. It is interesting to note, writes the United States Consul at Tunis, that for the fine sponges which the Kerkenna fishers obtain the Sfax prices are from 32 francs per kilo.; sponges from the Gulf of Gabes, of ordinary quality, fetch 27 francs per kilo. (formerly from 12–14 francs). The harpoonists are bringing in good sponges, poorly dried and cleaned, which are sold at 32 francs a kilo. in Sfax. The Kerkenna sponges are sold without any preparation whatever, the buyers themselves cleaning the delicate tissues. The price of these sponges, adds the Consul, will shortly be 50 francs a kilo.

Concrete Aggregates.—The Concrete Institute has recently collected, in tabular form, a variety of useful information on the properties of aggregates available in different parts of the country. The collection of this information has been made possible by the co-operation of a number of county and borough engineers, who have furnished particulars upon forms provided by the Institute. By this means a large amount of valuable information has been made accessible to all who are interested in concrete work, and who wish to ascertain what aggregates are available in any particular district. The investigation is not yet completed, but the tabulated information at present collected is open for inspection, free of charge, on application to the Secretary of the Concrete Institute, at Denison House, 296, Vauxhall Bridge Road, Westminster, S.W. 1.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

May 12.—Graily Hewitt, "Rolls of Honour." Halsey Ricardo, F.R.I.B.A., will preside.

May 19.—John Somerville Highfield, M.Inst.C.E., M.I.E.E., W. R. Ormandy, D.Sc., and D. Northall-Laurie, F.I.C., "The Commercial Application of Electrical Osmosis." Alan A. Campbell Swinton, F.R.S., will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m.:—

May 20.—Brigadier-General Lord Montagu of Beaulieu, K.C.I.E., C.S.I., "Roads and Transport in India." Lieut.-General Sir Herbert V. Cox, K.C.B., K.C.M.G., C.S.I., Military Secretary, India Office, will preside.

Monday afternoon, at 4.30 p.m.:—

May 31.—Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Friday afternoon, at 4.30 p.m.:—

June 18.—Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

INDIAN AND COLONIAL SECTIONS.
(Joint Meetings.)

Friday afternoons, at 4.30 p.m. :—

MAY 28.—PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

JUNE 4. — PROFESSOR SIR JOHN CADMAN, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

CANTOR LECTURES.

Monday evenings, at 8 p.m. :—

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

Syllabus.

LECTURE II.—MAY 10.—The second lecture continues the subject in greater detail through a selection from the most characteristic works by Robert Adam, dealing more particularly with the interiors and decoration of his famous houses.

LECTURE III.—MAY 17.—The third lecture is devoted to Sir John Soane, and traces his relations to the movement begun by Robert Adam and to the Greek and Mediæval revivals. Soane's ideas on architecture and decoration are discussed in relation to his more important works. In conclusion, it is pointed out that three-quarters of a century is covered by the work of Robert Adam and John Soane.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 10 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. A. T. Bolton, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." (Lecture II.)

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. S. A. Smith, "Rent Problems."

Geographical Society, Kensington Gore, W., 5 p.m. Mr. G. Dobson, "Instruments for the Navigation of Aircraft."

TUESDAY, MAY 11 ... Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Captain J. W. Barber, "Recent Developments in Portable Types of Cinema Outfits."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology—The Invaders of England." (Lecture III.)

Photographic Society, 35, Russell-square, W.C., 7 p.m. Professor A. Findlay, "Some Properties of Colloidal Matter and their Application in Photography." (Lecture II.)

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Dr. W. J. Dakin, "Fauna of Western Australia. III. Further Contributions to the Study of the Onychophora." 2. Mr. C. Forster-Cooper, "Chalicotheroidea from Baluchistan." 3. Dr. W. T. Calman, "Notes on Marine Wood-boring Animals.—I. The Shipworms (*Teredinidæ*)."

Colonial Institute, Central Hall, Westminster, S.W., 8 p.m. Mr. F. C. Wade, "Through British Columbia by Cinema."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m. Sir Daniel Morris, "The Use and Relative Value of Trees in Great Britain."

WEDNESDAY, MAY 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. Grailly Hewitt, "Rolls of Honour."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Major Linton Hope, "Flying Boat Hulls."

THURSDAY, MAY 13...Inventors, Institute of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Mr. D. Leechman, "The Relations of the Inventor to the State."

Royal Society, Burlington House, W., 4.30 p.m.

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. T. C. Thompson, "The Scripts of Ancient Mesopotamia and their Decipherment: the Origin of our Alphabet."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. P. Graves, "Welsh and Irish Folk Song."

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. B. Williams, "Minorities in War Time."

Auctioneers and Estate Agents' Institute, 34, Russell-square, W.C., 3 p.m. Mr. E. H. Blake, "The Institute: A Glance into the Past."

FRIDAY, MAY 14...Federation of Laundry Associations, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Iron and Steel Institute, at the University, Sheffield, 3 p.m. 1. Messrs. J. H. Andrew, J. E. Rippon, C. P. Miller, and A. Wragg, "Effect of Initial Temperature upon the Physical Properties of Steel." 2. Messrs. C. A. Edwards, H. Sutton, and G. Oishi, "The Properties of Iron-Chromium-Carbon Steels." Part I., Thermal Analysis, Messrs. C. A. Edwards and A. L. Norbury, "The Properties of Iron-Chromium-Carbon Steels." Part II., "Effect of Heat Treatment on Electrical Resistivity." 3. Messrs. K. Honda and T. Murakami, "On the Structural Constitution, Hardening and Tempering of High-Speed Steel containing Chromium and Tungsten." 4. Mr. J. H. G. Monypenny, "The Structure of some Chromium Steels." 5. Mr. A. L. Norbury, "The Effect of various elements on the Electrical Resistivity of Iron." 6. Mr. F. Rogers, "Brittleness of Nickel-Chrome and other Steels" (Part II).

Royal Institution, Albemarle-street, W., 9 p.m. Professor J. K. Pearson, "Sidelights on the Evolution of Man."

Sanitary Institute, Town Hall, Scarborough, 7.30 p.m. Dr. J. R. Kayes, "Inconsistances in Personal and Communal Hygiene."

Malacological Society, at the Linnean Society, Burlington House, W., 8 p.m.

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Dr. S. Ahmad Khan, "The Developments of Modern Educational Institutions in India." (Lecture II.)

Astronomical Society, Burlington House, 5 p.m.

Automobile Engineers, Institution of, at the Technical Institute, Coventry, 7.30 p.m. Mr. J. E. Hurst, "Cast Iron in relation to the Automobile Industry."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Dr. F. Lloyd Hopwood, "Demonstration of Experiments on the Thermionic Properties of Hot Filaments." 2. Mr. G. D. West, "A Modified Theory of Crookes Radiometer." 3. Mr. A. Campbell, "On the Magnetic Properties of Silicon-Iron (Stalloy) in Alternating Fields of Low Value." 4. Mr. T. Smith, "On Tracing Rays through an Optical System."

SATURDAY, MAY 15...Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. Harrison, "A Philosophical Synthesis as proposed by Auguste Comte."

Journal of the Royal Society of Arts.

No. 3,521. VOL. LXVIII.

FRIDAY, MAY 14, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MAY 17th, at 8 p.m. (Cantor Lecture.) ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." (Lecture III.)

WEDNESDAY, MAY 19th, at 4.30 p.m. (Ordinary Meeting.) JOHN SOMERVILLE HIGHFIELD, M.Inst.C.E., M.I.E.E., W. R. ORMANDY, D.Sc., and D. NORTHALL-LAURIE, F.I.C., "The Commercial Application of Electrical Osmosis." ALAN A. CAMPBELL SWINTON, F.R.S., will preside.

THURSDAY, MAY 20th, at 4.30 p.m. (Indian Section.) BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., "Roads and Transport in India." LIEUT.-GENERAL SIR HERBERT V. COX, K.C.B., K.C.M.G., C.S.I., Military Secretary, India Office, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, May 10th, Mr. ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, delivered the second lecture of his course on "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837."

The lectures will be published in the *Journal* during the summer recess.

EXAMINATIONS.

The number of entries for the second series of examinations of 1920, which commenced on the 10th inst., and will finish on the 19th inst., is 36,326. The total entries for both examinations is 54,010. This is 19,834 in excess of the entries received in 1919, when the total for both examinations was 34,176. Previous to this year the highest number of entries received was in 1914, when the number was 37,978.

TWENTIETH ORDINARY MEETING.

WEDNESDAY, MAY 12th; Mr. HALSEY RICARDO, F.R.I.B.A., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Booth, Frederick Augustus, Harborne, Birmingham.
Hegarty, R. D., London.
Kent, T. O., East Molesey, Surrey.
Miller, Frank, Beckenham, Kent.
Preater, Charles John, M.Inst.Met., Bath.

The following candidates were balloted for and duly elected Fellows of the Society:—

Anderson, Sir Alan Garrett, K.B.E., London.
Dunning, Major James, D.S.O., London.
Hart, Charles, F.S.S., Moseley, Birmingham.
Howard-Flanders, Richard Leonard, M.I.Ae.E., Latchingdon, Essex.
Kneass, Strickland L., Philadelphia, U.S.A.
Mayrow, J. J., London.
Sherrill, Brigadier-General Charles H., LL.D., New York, U.S.A.
Visvesvaraya, Sir M., K.C.I.E., M.Inst.C.E., London.

A paper on "Rolls of Honour" was read by Mr. GRAILY HEWITT, B.A., LL.B.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 24th; SIR HENRY TRUEMAN WOOD, M.A., Vice-President and Chairman of the Council, in the chair.

The paper read was—

INDUSTRIAL LIGHTING AND ITS RELATION TO EFFICIENCY.

By Leon Gaster,
Hon. Secretary of the Illuminating Engineering Society.

Rather more than seven years have elapsed since I had the honour of addressing the Fellows of the Royal Society of Arts on the subject of industrial lighting, emphasising especially the economic and hygienic advantages of good illumination. It is now my privilege to give a further summary of progress made in this field. The Royal Society of Arts has invariably been to the fore in dealing with matters affecting the welfare of workers and the efficiency of industrial operations. It has interested itself in such matters as heating and ventilation, and by inviting me to deliver the series of Cantor Lectures on "Modern Methods of Artificial Lighting," in 1909, it had already given its approval to the principle that all illuminants ought to be considered conjointly, with a view to their proper application in practice to the service of mankind.

In little more than a year after my last paper before the Society on "The Economic and Hygienic Advantages of Good Illumination," the outbreak of war took place. Events during the subsequent five years, while in some respects retarding scientific development of illumination, served to emphasise the great importance of adequate industrial lighting in the interests of health, safety and efficiency. There is no industry in this country which does not involve the use of light as a necessary element in production. During a period when the factories of the country were striving to produce their maximum output, this point was inevitably recognised, and at the present time there are several industrial tendencies which make it specially important that the influence of lighting should be properly studied.

We are concerned with two inter-related problems. There is a general recognition that we must increase our powers of production to the utmost. At the same time there is industrial unrest which impedes our efforts towards reconstruction. Lighting, as I shall show, has an important bearing on both aspects. It is intimately connected with efficient production, but it should also be considered in relation to conditions of labour from the worker's standpoint. When conditions are bad there is inevitably discontent, and there is little doubt that in the past unsatisfactory lighting has increased this tendency by adding to the hardships and dangers of many industrial operations. Moreover, it will be generally agreed that our industrial problems should be ultimately solved in such a way that the worker has every incentive to increased production. The one dangerous factor is deliberate restriction of output.

In the future, therefore, output must be assisted in every possible way. There are several tendencies already operating in this direction. One of these may be the extension of the "three-shifts" system, whereby the hours of labour can be shortened, but the machinery used in the most efficient manner. As Lord Leverhulme has put it, we must "sweat the machinery, not the workers." Now the extension of this system means the carrying out of an even larger proportion of work by artificial light than at present. During the war the proportion of work done by artificial light increased greatly, owing to the need of getting more work out of existing plant and factory space. We may expect this method to become more general, but it will only be successful if special pains are taken to ensure that the lighting is scientifically designed for the work; so that ultimately work by night may be no less efficient and no more fatiguing or dangerous than work by day.

Another tendency is towards the standardisation of industrial processes. This intensive production demands specially good lighting, because the failure of any link in the process disorganises the whole. Bad lighting, besides slowing down some stage in the process, is liable to cause harassing breakdowns and disorganisation. In such processes, parts must be not only accurately made, but interchangeable, and this perfection of work can only be attained when the light is scientifically directed and adapted to the purpose in view. During recent years the order of accuracy demanded has become much greater than in the past. It involves the use of the finest tools, maintained in perfect condition. Among such tools, light is one of the most important and most universally employed.

I now propose to consider in turn the influence of illumination on health, accidents, and efficiency of production, and subsequently to explain some of the chief principles of good lighting, and to suggest measures to secure it.

Industrial Illumination and Health.

The close relation between light and health

has long been recognised by physicians. It is known that absence of light is favourable to the development of tuberculosis and certain other diseases, besides increasing the risk incurred in various dangerous trades. In the case of such trades, notably those concerned with vitreous enamelling and in underground bakeries, the Home Office regulations in this country have, for many years, required good lighting. Moreover, employees work more cheerfully in well-lighted premises, whereas dark and gloomy surroundings are depressing to the spirits. It has also been found that where the lighting is good, more attention is paid to cleanliness and personal appearance. In all ill-lighted factories refuse is apt to collect, whereas in a well-lighted interior its presence would be obvious, and it would be accordingly removed. Naturally, when poisonous materials have to be handled, the risk to health is greater if workers cannot see clearly refuse-material which collects on their work and persons. In those cases where work is necessarily done to a great extent by artificial light, and especially where, owing to the large area occupied, it is impracticable to reproduce the conditions prevailing in a well-lighted factory, the risk of ill-health is particularly great.

Furthermore, bad illumination enormously increases the effort of working, especially work that makes a severe tax on the eyesight (*e.g.*, in the clothing, sewing, and textile and embroidery trades). This strain may show itself in various ways in the form of headaches, eyestrain, or general lassitude. The investigations carried out on industrial fatigue have shown, by delicate tests, how vitality is gradually sapped during a severe day's work, and how recuperation sets in during the night's rest. These data have furnished strong evidence in favour of the limitation of hours of work, and the provision of reasonable pauses for recuperation. When to the normal strain of exacting work there is added the additional effort imposed by inability to see the work in comfort, or to follow with ease the working motions of complicated machinery, it can readily be judged how the period before fatigue sets in may be shortened. The effect of inadequate lighting in thus causing fatigue is one subject that might well receive attention from the recently formed Research Board appointed by the Department of Scientific and Industrial Research and the Medical Research Committee last year. The field of work of this Committee covers a general survey of the relation of hours of work and other conditions of employment to the production of fatigue, having regard both to industrial efficiency and the preservation of health.

We have, however, already important evidence indicating generally the prejudicial effects of inadequate lighting, although this matter requires further study in detail. At the time of my paper before the Royal Society of Arts in 1913, the Departmental (Home Office) Committee on Lighting in Factories had already been formed, and its researches were being conducted. It will be recalled that Sir Arthur Whitelegge, then H.M. Chief Inspector of Factories, and a member of this Committee, presided at the meeting of the Royal Society of Arts at which the paper was delivered. In 1915 the Committee issued a most comprehensive interim report, to which I shall frequently have occasion to refer, and in which the detrimental effects of inadequate lighting were very clearly recognised. The Committee in this report remarked:—" . . . there is a general impression that unsatisfactory lighting is, in various ways, prejudicial to health. It is also recognised that insufficient light adds to the difficulty of the proper supervision of work, and of the maintenance of cleanliness and sanitary conditions generally."

During the war there were many opportunities of confirming these impressions, owing to the large number of factories under State control and under special supervision. Most valuable work in studying the conditions in such factories was done by the Health of Munition Workers Committee (M.O.M.), and I cannot do better than also quote some of the conclusions of this Committee, as set out in its booklet on "The Health of Munition Workers":—

"The results of inadequate illumination are damage to eyesight and personal health, various forms of domestic insanitation, accidents in factories and workshops, often accompanied by diminution in output of work and lack of discipline. Bad lighting affects output unfavourably, not only by making good and rapid work more difficult, but by causing headaches and other effects of eyestrain."

The special question of the effect of inadequate lighting on output, which is an economic one, will be dealt with more fully later. But it is at once apparent that there is a double case for the provision of adequate lighting in the interests of health. The case rests primarily on humanitarian grounds, that it is intolerable that workers should be exposed to injurious conditions; but, in addition, the case for good

lighting, as we shall see, is equally strong from the purely economic side.

The next question we shall consider, the effect of inadequate illumination in causing accidents, is closely related to that with which we have just dealt. It may be taken for granted that, where possibilities of accidents exist, the dangers are accentuated if the illumination is such as to affect the health of workers prejudicially. There are, however, special precautions to be taken in connection with illumination, according to the nature of the processes carried on.

Bad Illumination as a Cause of Accidents.

For some years the part played by poor conditions of illumination in causing accidents has received study, and there is already available a great deal of information on this point. It is obvious that accidents, which so often arise from failure to perceive, will often be associated with inadequate illumination. Cases on record include men carrying molten metal in ironworks, who have stumbled over unseen obstacles and injured themselves with the hot metal; men working in feebly lighted workshops, who have failed to see clearly the outlines of moving machinery, and become entangled with it; men working in dockyards or on scaffolding, who have lost their footing because the illumination was not sufficiently well devised to reveal loose planks or pits, etc.; men working on railways or in yards, who have been run over by trains, trolleys, etc., because the lighting was not adequate. In many cases accidents are due to insufficiency of light, but they may be due to other defects; for example, the dazzling effect of a bright light in dark surroundings, or the confusing shadows or abrupt transition from brightness to darkness caused by imperfectly diffused sources of light. Steep stairs and raised platforms with exposed edges, should always be well lighted. It is not enough merely to secure sufficient illumination on the area in question; *the light should be shaded so that the worker's eyes cannot be dazzled by the glare.*

Of all forms of accidents liable to be caused by inadequate lighting, special prominence may be given to those arising through "persons falling." This was strongly brought out in the data collected by the Departmental (Home Office) Committee on Lighting in Factories and Workshops, which reported in 1915. It was shown that such accidents are much more prevalent during the darker winter months than in the summer time. For a large number of industries the accident rate by night and by day was studied. Almost invariably the rate by night was considerably higher, the average increase for all industries being 29 per cent. for all forms of accidents, and 71 per cent. for persons falling. In the case of docks, where this type of accident is common, the increase was 102 per cent.

Some valuable confirmatory evidence was given by Mr. R. E. Simpson recently before the Illuminating Engineering Society in the United States. In that country also the number of accidents in each month of the year has been tabulated, and the same conclusion reached. A careful survey of industrial accidents and lighting conditions might enable us to correct many existing faults, and bring the accident rates by night and day into closer equality. Theoretically there seems no reason why artificial lighting in most factories should not be as suitable for the purpose as average daylight. Indeed, artificial light has the advantage of being strictly under control, capable of adjustment between wide limits, and, once installed, much more constant than natural lighting, which varies enormously according to climatic conditions.

The conditions of access of daylight into buildings, I need scarcely add, also require careful treatment, so much so that the general arrangement and shape of modern factories is very largely governed by this consideration. It would be of great assistance to the lighting expert if architects, in planning buildings, would likewise bear the requirements of artificial lighting in mind, and confer with the illuminating engineer at an early stage in the design.

In the United States much excellent work has been done by "Safety First" Committees, established by many leading manufacturers to examine and correct causes of industrial accidents. On such committees both employers and workers are represented, and remarkable reductions in the number of accidents have been made by their efforts within quite a short period. Thus on all American railways, deaths and injuries were reduced by 46 per cent. in 1916, and large industrial concerns have recorded decreases ranging from 24 per cent. to 84 per cent. since the movement was initiated. The "Safety First" movement in the United States receives very powerful support. Lord Leverhulme, who mentioned this fact in summarising his experiences during a recent visit to the United States, has also stated that

the beginning of the "Safety First" movement was made in this country; it is only in recent years that developments in the United States have proceeded more rapidly than here.

However, since the outbreak of war the matter has been energetically taken up by the London "Safety First" Council, and its off-shoot the British Industrial "Safety First" Association. The valuable work which these bodies have already accomplished is very largely due to the energy of Mr. H. E. Blain, one of the hon. secretaries, and the moment was certainly opportune for the inception of this work. The great losses suffered by this country during the war render it of vital importance to take all possible measures to check the continuous drain on our resources through accidents to life and limb. Two years' work by the London "Safety First" Council, in connection with street accidents, has been accompanied by a decrease in fatal accidents of 24 per cent., and in accidents to persons and property of 36 per cent. By the formation of the British Industrial "Safety First" Association, which has just completed its first year of existence, this work has now been extended to the industrial field. Machinery is being prepared to facilitate an analysis of the causes of accidents in factories, amongst which inadequate lighting takes an important place. At a meeting of the Illuminating Engineering Society in 1918 the author presented a table showing how the necessary data could be obtained on a uniform basis, and there is no doubt that by the application of a schedule of this description, much valuable information as to the part played by industrial lighting conditions in relation to accidents might be obtained.

One of the first steps taken in this direction by the British Industrial "Safety First" Association has been the issue of a publication explaining in simple language the part played by lighting in relation to health, safety, and efficiency, and the fundamental principles to be applied in order to secure adequate illumination.

An attempt to trace the relation between inadequate illumination and accidents has also been made in the United States. Mr. R. E. Simpson, in the paper referred to above, quotes statistics obtained by the Travellers Insurance Co., who estimated that of 91,000 accidents studied in 1910, 23·8 per cent. were due to imperfect illumination. After eight years' work this proportion has been reduced to 18 per cent., but even so it is estimated that during this period the services of 108,000 men for one year have been lost through preventable accidents.

In this country the Home Office statistics for 1914 showed that 969 persons were killed and 147,045 injured in factories alone, and this refers to reported accidents, and does not include a large number of minor accidents. The official returns under the Workmen's Compensation Act for 1913 showed that £3½ million were paid in respect of nearly 4,000 deaths and 477,000 disablement claims. If, by the application of scientific principles of lighting, a reduction of only 10 per cent. in this large figure could be made, it would be well worth while, especially when the secondary economic loss through time wasted and disorganisation is also taken into account.

The prevention of industrial accidents due to faulty lighting is thus a measure which is amply justified on economic grounds alone, besides being, of course, a measure which ought to be taken in the interests of humanity.

I shall now proceed to consider the effect of illumination on the quality of work and output. For various reasons it is not so easy to trace a direct monetary advantage from good lighting as to show its effect on health and in preventing accidents, but there are data available which justify the belief that these advantages far outweigh the cost involved.

The Effect of Illumination on Output and Efficiency.

It is evident that failure to provide adequate illumination greatly increases the difficulty of supervision and accentuates the tendency to slackness, where this exists. On the other hand, good lighting has a bracing effect and inclines men to put out their best efforts. It is clear, too, that a skilled worker cannot put forth his best efforts if he is hampered by difficulty in seeing what he is doing, and that it is folly to pay high wages and instal expensive machinery and then to grudge the relatively small expenditure necessary to put the lighting on a proper basis. The high order of accuracy, the high speed of machinery, and the use of automatic methods make the results of inadequate lighting specially serious. If a tool is wrongly set, a great deal of work may be turned out before the error is rectified. Bad lighting reveals its effect both in slowing down operations and in increasing the amount of spoiled work. This applies alike to engineering operations where things must be made to exact dimensions, and to textile processes where the surface of the

material must be carefully studied. Good lighting is essential for the inspection of materials, but an injustice is done to the workers if the lighting conditions by which they execute the work are not as good as those by which the work is subsequently inspected.

Evidence of increased output following improvement in illumination was given by several witnesses before the Departmental Committee on Lighting in Factories and Workshops. In one case noted the earnings of workers increased 11·4 per cent. after the installation of better lighting; in another case the output by artificial light, owing to faulty methods of illumination, was 12·30 per cent. less than by daylight. The matter is of equal interest to managers and employees. The latter are quick to appreciate the connection between good lighting and earning power. Thus it was stated by Mr. Franklin Thorpe, in a paper read shortly before the war, that in the North of England workers tend to migrate continually to the better lighted mills. It is a common experience that when the lighting of one section of a factory has been improved, workers in other sections also clamour for a similar improvement. Moreover, whilst managers and workers are sometimes slow to admit the full economic benefits of good lighting, one finds that, once an improvement is made, neither will consent to return to the old conditions.

In order to trace scientifically the relation between lighting and output, it is necessary to conduct special experiments in factories for the purpose. Naturally, managers are reluctant to disturb their routine, although in many cases the experience gained would fully justify any loss occasioned by change of procedure. An interesting experiment was recently conducted in Chicago by the Commonwealth Edison Company, which, like other American supply companies, also supplies lamps and fittings and can therefore readily make a survey of lighting conditions. A survey was made of ninety-three factories, totalling 17,400 employees. Wide variations in illumination and consumption of electricity were found, but an average of 1½ foot-candles,* 0·33 watts per square foot, and 80 watts per employee were noted.

Now, according to the code of lighting adopted by the Illuminating Engineering Society in the United States as representing good modern practice, the average illumination should have been 5·5 foot-candles, and the variation in illumination, according to the process, which was actually 0·01–10 foot-candles, should have been 2–12 foot-candles. A programme of experiments, covering four months, and taking full account of both lighting conditions and output, was then arranged. The first month was to run with the existing lighting, the second month with lighting to a value of illumination 50 per cent. above that required by the code, the third month at the lower code level, and the fourth month again at the higher illumination.

The chief difficulty was to find factories which could maintain the requisite check on output, and to induce owners to return to the lower illumination for the purpose of test, after the illumination had once been raised. But tests have already been made on eleven plants, and in some cases remarkable results secured. Thus, in one case the improved illumination resulted in an increased output ranging from 8 to 27 per cent. in different departments when the illumination was increased three times, *i.e.*, from 4 to 12 foot-candles. In another case, where the illumination was twenty-five times the inadequate value originally employed, increases in output of from 30 to 100 per cent. were observed. On a conservative estimate it was concluded that an *increased cost of lighting amounting to not more than 5 per cent. of the pay-roll would lead to an increased production of quite 15 per cent.*

This remarkable experiment, conducted last year, gives a glimpse of the important effect which illumination may exercise on output. No doubt a painstaking investigation in this country would yield equally striking results. Tests conducted on the above basis are necessarily spread over a long period. But supplementary results could be obtained by quicker methods; for example, by timing with a stop-watch the time taken for various industrial processes by the existing illumination, and again when the lighting had been improved. By continual adjustment of lighting conditions and repetition of this test, the ideal conditions would ultimately be obtained.

At present experience shows that there is no consistency in the lighting of factories. One finds in different works great variations in the amount of illumination provided for identical processes. Evidently either some of the factories are inadequately lighted, or others are extravagantly lighted. It seems likely, however, that in most cases the amount of illumination could

* A foot-candle is the illumination produced by a source of one-candle power at a distance of one foot. It is possible to specify and measure the illumination in foot-candles at any spot, quite irrespective of the number and arrangements of the lights producing this illumination.

with advantage be increased without trespassing beyond the upper limit beyond which an increase in the amount of light has no marked economic advantage.

Some simple experiments, which would serve as a model for more detailed investigations, were made by the National Physical Laboratory in connection with the researches of the Departmental Committee on Lighting in Factories and Workshops. The experiments were made with seamstresses from the workrooms of some of the chief London outfitting firms, the illumination being first adjusted to a value which was admittedly too low for efficient working, and then raised until there was agreement that the amount of light was sufficient. By repeating this experiment, the necessary minimum illumination for comfortable work was ascertained with fair accuracy. A point of great consequence is the nature of the material worked with. Thus black material required 5 to 6 foot-candles, whereas with white cloth a much lower value appeared sufficient. Roughly, the product of the necessary illumination on work and the reflecting power of the material remained constant. In other words, there was a *minimum brightness of material necessary* for efficient work.

Cost of Lighting in Relation to Wages and Equipment.

The economic advantages of proper industrial lighting are again emphasised when one considers the proportion that the cost of lighting forms of other industrial expenses. Mr. Clewell, in a recent article in "Industrial Managements," took as a typical example a room with a floor area of 3,000 sq. ft., in which twenty-five employees were at work, earning on the average 25 cents (approximately 1*s.*) an hour. The total annual wages bill for this area might amount to \$25,000 (say £5,000), including superintendence and overhead charges. The annual cost of lighting the area should not exceed \$250 (say £50), from which it appeared that the lighting costs only 1 per cent. of the wages bill. Naturally, the exact proportion will depend on the wages paid, but it is invariably small. If all the other items forming standing charges on the factory were included, the proportion would be smaller still. Only a very small improvement in output would be needed to compensate for the cost of better lighting, quite apart from the other advantages referred to previously, such as better health of employees, less fatigue and nerve strain, etc., all of which are difficult to assess commercially.

The results are equally striking if one compares the cost of *installing good lighting* with the total cost of the erection and equipment of large factories. Thus Mr. Clewell found that in the Ford Motor Works in the United States the cost of buildings and equipment amounted to \$1·64 (say 6*s.* 6*d.*) per sq. ft. of floor area, while the lighting installation cost 5 cents (approximately 2½*d.*) per sq. ft., *or only* 3 *per cent. of the entire first cost.* In this case also the running costs of lighting were small in comparison with the total operating charges, forming only about $\frac{1}{10}$ per cent.

Those cases in which managers are disposed to grudge adequate expenditure on lighting may be due to inability to perceive the vital bearing of good illumination on efficiency of work. Another point, especially in the case of factories running almost continuously, is the disturbance which an alteration in the existing lighting necessarily causes. The manager must therefore weigh against the inconvenience of a temporary stoppage of part of the factory, the advantages which will ultimately accrue through the improved lighting. But in the case of a *new* installation this difficulty does not occur, and there is every reason for advocating the most careful and scientific planning of the lighting in such cases.

I may also add, that improvements in lighting do not necessarily involve greater expenditure. In many cases the advantages of better illumination may be secured by a re-arrangement of existing installation, a better choice and application of lighting appliances, and by the consequent avoidance of waste of light that arises from such appliances being injudiciously used. In such cases the advantages to the manager are twofold. He obtains the benefit of economies in the use of gas and electricity, and the further gain of the better conditions of working secured as a result of the improvement in lighting made.

Some Important Points in Good Industrial Illumination.

Having shown the justification for proper industrial lighting, let me next refer to some of the most important principles involved. Scientific illumination is only obtained when lighting is studied in relation to the processes carried on. *The lighting expert needs to be familiar with these processes as well as his own speciality, the principles of illumination.* But as a result of the discussions before the Illuminating Engineering Society during the past ten years, the fundamental principles have been clarified, much

information on special lighting problems has been obtained, and there are now men in a position to give good advice.

One important element in progress has been the development of simple forms of instruments for measuring illumination. By means of many measurements of illumination in factories we have ascertained what great variations in illumination exist, and where waste occurs. We are able to verify, by actual measurement, estimates of the illumination to be provided. Above all, we know the existing order of illumination prevailing in factories, and can determine when recommendations are practicable. Thus the large number of measurements, upwards of 4,000, made by the Departmental Committee on Lighting in Factories and Workshops was extremely helpful in fixing standards.

Good lighting, however, is not merely a matter of providing sufficient illumination. Other important points include:—Uniform illumination over the working area; the placing or shading of lamps so that the light does not fall directly in the eyes of workers when engaged on their work, nor when looking horizontally across the workroom; the placing of lights so as to avoid the casting of inconvenient extraneous shadows on the work.

The choice of suitable forms of reflectors, so as to secure even illumination and absence of troublesome shadows, is of great importance. Light tinted walls and ceilings are of great assistance in eliminating such shadows and promoting good diffusion of light.

It is most desirable that lamps, reflectors, etc., should be regularly cleaned and maintained. A few months' neglect may result in a loss of as much as 50 per cent. of the working illumination, and cases are on record where, by merely making good defects and cleaning lamps and appliances, the available illumination was doubled.

During the war manufacturers were so fully occupied in meeting demands for standard types of lamps and reflectors, etc., for essential work that there was not much opportunity for introducing new designs. Much attention has been devoted to industrial lighting, and the illumination of munitions works. It was fortunate that the leading firms concerned with lamps and lighting appliances had already formed illuminating engineering departments, and could thus both supply lighting apparatus and advise on its use. Here the country reaped the reward of the work of the Illuminating Engineering Society in the years preceding the war. Both gas and electric lighting have played a great part in promoting industrial progress. A feature of modern methods is the use of the latest and most efficient units, such as high-pressure gas or gas-filled ("half-watt") electric lamps, placed high up out of the direct view of workers, and affording a clear space for the supervision of the workroom. The electric gas-filled lamp, comparatively unfamiliar at the outbreak of war, has since been much used for industrial lighting, and great care has been devoted to the design of special fittings for use with this form of lamp. Amongst such devices may be mentioned the air-tight forms of lanterns suitable for use in munitions works, or placed where chemical fumes are present.

Lighting Conditions in Mines and the Eyesight of Miners.

Lighting in mines forms an important section of industrial lighting. Miners, however, are almost entirely dependent on portable lamps for the working illumination, which is thus far below the value usual in factories. In my paper before this Society in 1913, I referred to the effect of these peculiar conditions on the eyes of miners, especially in causing "miners' nystagmus." At the present time the prevalence of this disease still gives ground for much concern. Dr. T. L. Llewellyn, in a paper before the Illuminating Engineering Society on February 24th, 1920, estimated that upwards of 6,000 men are disabled each year through this disease, with a corresponding economic loss to the country exceeding £1,000,000. In the discussion of this paper, eminent representatives of the Council of British Ophthalmologists and the Ophthalmological Section of the Royal Society of Medicine took part, and there was general agreement that inadequate illumination is an important factor in causing the disease. Dr. Llewellyn suggested, as a first step, a standard of illumination on the working surface of not less than 0·1 foot-candles—a value with difficulty obtainable from lamps in use prior to 1914. It was suggested that the question should be thoroughly studied by a joint committee on which the Illuminating Engineering Society, the Council of British Ophthalmologists, and the Royal Society of Medicine should be represented. There is now sitting, under the Home Office, a committee which is making investigations on miners' lamps, and the suggestion will doubtless receive sympathetic consideration from this Department, which has done so much to encourage good lighting in factories. The problem is a highly complex one, involving inquiries extend-

ing over a number of years, in order to obtain satisfactory results.

Government Action on Industrial Illumination.

In my previous paper before the Royal Society of Arts in 1913, I detailed some of the steps taken by Governments in various countries in regard to industrial illumination. Holland, as far back as 1895, required adequate lighting in general terms, and in 1911 laid down more precise rules for lighting in factories where young people are employed, including a minimum illumination of 2–3 foot candles, according to the process.

In this country, strange to say, there has been no specific requirement of adequate lighting in the Factory Acts, although such a requirement was introduced into the Indian Factory Act in 1911, and occurs in the legislation of New South Wales. However, in certain trades definite requirements have been made, and actually a great deal more attention has been paid to industrial lighting than a mere inspection of the Factory Acts would suggest.

During the years preceding the war, the need of dealing with the matter on more comprehensive lines was recognised in several countries, notably at several international congresses, to which I referred in my previous paper in 1913. The report of the British Departmental Committee on Accidents in Factories and Workshops, issued in 1911, recommended that "general statutory power to demand adequate lighting" should be conferred on the Home Office. In the same year the Minister of the Interior in France appointed a Committee on Illumination; and early in 1913 the Home Secretary in this country announced the formation of the Departmental Committee on Lighting in Factories and Workshops. Shortly afterwards the Académie Royale de Médicine Belgique requested the Government to form a similar committee in Belgium.

In France and Belgium the outbreak of war interfered with the continuation of these inquiries, but the Committee in this country persevered with its work, issuing an interim report in 1915, which is justly regarded as a landmark in the official treatment of industrial lighting.

This report endorsed the recommendation that there should be statutory provision for requiring adequate and suitable lighting in factories, and giving power to the Secretary of State to make orders defining such conditions. It also contained specific recommendations on the amount of illumination necessary in the interests of safety, but deferred for further consideration the question of the illumination needed for various processes of work. This country can justly claim to have been in advance of others in carrying through this valuable inquiry, but owing to the interruption of work caused by the war the carrying out of the Committee's recommendation with regard to the insertion of a definite requirement of adequate lighting in the Factory Acts was deferred.

It is curious that in this matter, as in the case of the "Safety First" movement, this country did the pioneering work, but, judging from the vast amount of published literature in America it might appear that this country had fallen behind in the development of the original idea. In the course of a visit to the United States in 1912, I gave a summary, before the Illuminating Engineering Society in that country, of progress in Europe, dwelling chiefly on the need for official recommendations on industrial lighting. The idea has since been adopted with enthusiasm in the United States, and, being relatively unhampered by war conditions, that country was able to profit by the experience of Europe. There are now six States—Pennsylvania, New Jersey, New York, Wisconsin, Oregon, and California—which already possess definite codes of industrial lighting, while others are expected to adopt similar procedure in the near future.

The various codes are based largely on that prepared by the American Illuminating Engineering Society, and follow closely the recommendations of the Home Office Departmental Committee in this country. In some respects they are more explicit, *e.g.*, in stating definite values for various kinds of work, besides general values in the interest of convenience and safety. The codes appear to have worked well. Manufacturers have proved anxious to comply with their requirements, and the chief need has been for educational measures to ensure that they are properly understood. Thus the Museum of Safety in New Jersey contains exhibits of various lighting systems. (This is a step which, I believe, was contemplated by the Industrial Museum in this country immediately before the war, under the supervision of the Home Office. The building was complete, but was necessarily converted to war needs, but one may hope that it will now revert to its proper use.) In New York, again, factory inspectors attend a departmental school, where the results of tests of lighting installations are presented and discussed.

In order to show that these codes are in actual operation, the following table, presented by Mr. Vogt, of the New York State Labour Department, in a recent discussion before the American Illuminating Engineering Society, is of interest:

	Orders issued.	Compliances.
August, 1918	35	27
September, 1918	174	67
October, 1918	611	88
November, 1918	546	156
December, 1918	446	205
January, 1919	608	517
February, 1919	765	506
Totals	3,185	1,566

Thus the proportion of compliances steadily increased, and 50 per cent. of orders for improvements made during this period have already been met.

Now, in the United States each State acts on its own initiative, and although the general principles adopted in the industrial codes are substantially similar, the procedure is not identical. This, it is pointed out, is illogical; while the more progressive States have adopted legislation, the great majority still have none.

In this respect Great Britain is in a more fortunate position, and I am anxious that this country should maintain the lead which it formerly held in this matter. The action taken by the Home Office would apply generally throughout the country, and it only remains to translate the recommendations of the Departmental Committee into actual fact. Our knowledge has considerably advanced since the year 1915, when the report of this Committee was issued, and it is only now desirable to continue its interrupted work so that other matters not yet reported upon may also be settled.

Indeed, so rapid is the development of knowledge on lighting matters, that it may be urged that a Committee of this description should be a permanent one. However satisfactory the recommendations of the moment may be, they are sure to require modification and extension in the future as our facilities for lighting improve and our knowledge of what constitutes good illumination becomes more perfect.

The essential point is that good lighting should now be regarded as of vital importance to safety, health, and efficiency of work, in the same manner as adequate heating and ventilation, and that a definite requirement of adequate lighting should be inserted in the Factory Act to this effect.

International Action on Industrial Illumination.

We should, however, not be content with securing suitable action in regard to industrial lighting in this country. In the long run it is always a drawback to civilisation when some nations are far behind others in development; the more general the practice of sound principles the better for everyone.

In my paper before this Society in 1913, already indicated the desirability—which was strongly endorsed by the Chairman of the meeting, Sir Arthur Whitelegge—of Committees being formed in all the chief countries of the world to deal with industrial lighting, and the interchange of experience between them, thus paving the way for international action. These expectations would doubtless have been realised but for the disturbance caused by the war. Experience during the war has greatly stimulated the desire for international co-operation, and it may be foreseen that in the near future there will be international machinery for dealing with this and other industrial questions. We see already indication of such international action in the work of the Committee that has been sitting in Paris in order to deal generally with labour conditions. In conferences of this nature one would like to see this country, which has behind it such a fine record for enlightened action in regard to industrial hygiene, again taking the lead in dealing with illumination.

One point, in conclusion, I should like to emphasise—that these measures for promoting good industrial lighting will, if wisely contrived and administered, meet with general good-will. The step is not a sudden one, but it is based on experience gradually accumulated during the past ten years. There is now such a general recognition of the importance of good illumination as a means of preserving health, preventing accidents, and improving output, that managers and workers alike will welcome measures likely to bring about an improvement. It will be essentially a case of "government by consent."

We in the Illuminating Engineering Society have always adopted this principle in suggesting measures for the improvement of existing practice in illumination. It will doubtless commend itself to the Royal Society of Arts, to whose sympathetic encouragement we owe so much. I would like to express my personal appreciation of the advice and help we have received from Sir Henry Trueman Wood, and it is a great pleasure to me that he is able to preside. This principle of securing general consent and approval before taking action has been largely instrumental in securing for our movement such generous assistance from the daily and technical

Press, whose help in making our objects widely known I desire also to gratefully acknowledge.

Since the Illuminating Engineering Society has taken charge of the subject of illumination, the Royal Society of Arts, in accordance with their usual practice in the case of special bodies formed under their wing, has left to us the working out of details in this field. We, in turn, gladly take the opportunity, as occasion arises, to bring before the Society surveys of general progress in the lighting field. I hope that in years to come I may have the privilege of recording further advances both in the efficiency of lighting appliances and in their application in the service of mankind.

DISCUSSION.

THE CHAIRMAN (Sir Henry Trueman Wood), in opening the discussion, said Mr. Gaster had added one more to the list of papers he had read before the Society, for the first of which, given in 1906, he had obtained, and thoroughly deserved, the Society's Silver Medal. His most important contribution was a course of Cantor Lectures on Illumination, which were remarkable for the excellent way in which they were illustrated. The formation of the Illuminating Engineering Society resulted from those lectures. That Society had been founded by Mr. Gaster, and he had been its moving spirit ever since. It had done an infinity of good work by bringing together the clashing interests dealing with illumination, and by disseminating knowledge on the subject. In his present paper Mr. Gaster had brought together a great deal of most valuable information; and the general conclusions at which he had arrived would, he thought, be generally accepted. As to whether legislation was required or not, he could not personally offer an opinion, but it was, at all events, a legitimate subject for discussion whether the supervision of factory lighting should not be brought into the scheme of factory inspection. The amount of light required in various industries varied considerably, and that was a difficulty which would have to be faced if legislation were to be introduced. The ideal condition would be to have sufficient artificial light to be an alternative to daylight, and that, of course, had an important bearing on a question which he hoped would be further urged and developed—the use of shifts of workmen, so that the untiring machine might work the full twenty-four hours, while the workman himself would only be forced to labour for such time as suited his health and convenience. Before such a scheme could be introduced, however, the work-people would have to be convinced that they would be given a fair share in the benefits resulting from the economy so effected. In the past the benefits of any increased economy had gone to the capitalist, and the workmen were apt to think that that would be the case in the future. They had to be shown that if the scheme to which he had alluded was introduced they would get a fair share of the profits resulting from it, and obtain increased wages and decreased hours of labour. There were numerous other points in the paper, but he would leave them to discussion by technical experts who were competent to offer an opinion on them. He should have liked to have heard a little more about the construction of the apparatus Mr. Gaster had mentioned for measuring the amount of diffused light in a factory. There were many devices which might be used, and there ought not to be any difficulty in making an apparatus which could be carried in the pocket and yet be used to obtain quite good, if approximate, results.

DR. T. M. LEGGE (Medical Inspector of Factories) joined with the Chairman in thanking Mr. Gaster for his paper and for the lantern-slides accompanying it, which gave an excellent idea of what good illumination really meant. All progress was largely the work of enthusiasts, and he thought all those present would agree that Mr. Gaster was a man who knew his subject thoroughly, and who both in season and out of season would never let them forget that illumination was one of the most important things to be considered in factory construction. Mr. Gaster had referred to the Home Office Report, and had expressed a hope that the question of factory illumination might find a place in any new Factory Act. Such an Act could not be long delayed, and in it he hoped factory illumination would be referred to by a simple reference to the provision of adequate lighting, which was the way in which, he thought, Mr. Gaster would prefer to have it dealt with. Under the Act* of 1916 the Home Office had issued a number of brochures on such subjects as the Provision of Canteens, First Aid, Ventilation, and so on, and amongst them there was in preparation one on Lighting in Factories and Workshops, which would cover much of the ground traversed by Mr. Gaster that afternoon, and would deal with a great many of the points alluded to in the paper, such as health and efficiency of the workers, necessity of good lighting in regard to efficiency of work, prevention of glare, avoidance of shadows, etc., and finished up by giving the causes of, and remedies for, unsatisfactory lighting, which to a large extent could be summarised by "common sense." The only point of difference he had with Mr. Gaster was with reference to the fact—if it was a fact—that America was so far ahead of this country. Having just returned from the United States, and after having visited several towns and factories there, he dissented rather from the view expressed by Mr. Gaster that the Americans were so far ahead of this country in the "Safety First" movement. It must not be forgotten that America had a lot of leeway to make up, and that was what gave the impression that they were going ahead so fast.

---

* The Police Factories Miscellaneous Provisions Act.

He hoped the Illuminating Engineering Society would inaugurate a campaign against the too liberal use of lighting, as well as against the lack of it. Anyone who travelled in America would be impressed by the extraordinary progress of architecture in that country, and the beautiful proportions of many of the buildings; but one often found that the factory or business house or store was entirely spoilt by a hideous erection on the top, with reflectors and so on, to cast a brilliant light on the name of the proprietor.

MR. J. W. BEAUCHAMP said he had been very much interested in Mr. Gaster's paper, and he hoped some means would be found for giving it wide publicity. As one who frequently had, in the past, to bargain with industrial people about light in factories, he had been specially interested to hear how small was the relative cost of lighting —even good lighting—to other things, such as labour, material, etc. He was sure that was not generally realised. The psychological influence of lighting was a point worthy of attention. There was no doubt that the illumination of a factory had a considerable effect on the people who worked there. Diffused lighting had a lot in its favour, but if carried to excess it exercised a gloomy and chilling effect; on the other hand, a moderate degree of concentration had the effect of concentrating a man's attention on his work. It might be very uncomfortable to work in a bright spot in a dark room, but it was equally displeasing and depressing to work in a very much diffused light. He had felt—and he thought most workers with fine tools shared the feeling—that a decided spot light helped one to concentrate on one's work and prevented distraction. It was a small point, but he hoped it was one which the Society would consider.

MR. C. PIZEY considered the paper well worthy of careful consideration. Personally, he was more interested in domestic than industrial lighting, but he fully appreciated what Mr. Gaster had said as to the great value of efficient lighting in factories. There could be little doubt that, given efficient lighting, the output of the workers was considerably increased, and the quality of it improved.

MR. W. WYLD said he had listened to the paper with intense interest. He was sure that if Mr. Gaster's remarks were given wide publicity through the medium of the press they would do an immense amount of good. At the present time a number of factories were altogether out of date so far as their lighting was concerned, and their output was thereby diminished. He would like to hear more about the apparatus used in the lighting tests which Mr. Gaster had mentioned. It seemed to be a comparatively simple arrangement, very different from the cumbrous and often inaccurate instrument formerly employed. He thought the apparatus described should be taken up by illuminating engineers, and the scientific data thereby obtained form the basis on which all factories should be lighted in the future.

MR. J. S. DOW said Mr. Gaster had referred to the curious anomaly that so very often this country had originated something really fine and then allowed it to drop, after which it was taken up and developed by other countries. Legislation on factory lighting was a case in point. Of course the war had delayed matters, but now that impediment had been removed he hoped more progress would be made. He had been associated with Mr. Gaster for a long time, and thus had many opportunities of seeing that the authorities really did pay a great deal more attention to lighting than the mere fact that there was no reference to illumination in the Factory Acts would suggest. Deliberation had preceded action, and the Home Office Report of 1915 came just at the right moment, when people generally accepted the fact that good lighting was necessary in factories and when manufacturers had studied lighting sufficiently to be able to carry out what was expected of them. One thing he would like to see proceeded with was the formation of an industrial museum. Such a museum had been contemplated before the war, but the scheme had necessarily remained in abeyance until now. He believed it had been the intention to have a special section in that museum devoted to lighting. He thought the American States had gone a little too far in their Codes in the direction of elaborating details. What was needed was some broad general principles. With regard to lighting it could be said broadly that certain orders of illumination were required for different processes; and having said that, it might be left to the individual industries and the lighting experts to confer together and settle the details, and the Home Office authorities could act as guides and supplement the general recommendations by specific hints which would really be a help to manufacturers. That would be what Mr. Gaster wanted, legislation by consent. The real point was to get the necessary information disseminated so that everybody knew what to do. Another reason in favour of having an elastic framework was that they did not know yet what was the economical limit to which illumination could be carried. Some experiments in production made in the United States suggested that in course of time it might be found that much higher illumination than was demanded at present would be economically desirable. Their aim should be, therefore, to get the principles of good lighting clearly enunciated in their legislation, and then to have something in the nature of a permanent inquiry, conveniently carried on under the existing Departmental Committee on Lighting in Factories and Workshops, which could conduct investigations and collect data showing the kind of lighting required in various industries, and the exact relation it had to health, safety and efficiency.

Mr. R. Claude Bussell said that if ever an industrial museum such as had been suggested by Mr. Dow was formed, he hoped there would be a chamber of horrors attached to it—a museum of bad taste. It was unfortunate that the standard of lighting, adopted by the uninitiated was not what it would do but what it was, and the remark commonly made on a new lamp of any sort was, "A fine light." If anyone wanted to be really tortured, he should go down the Walworth Road on the top of a 'bus one winter's evening. From end to end it was a striking example of how not to do it. The amount of money thrown away there alone in lighting must be enormous.

Mr. Leon Gaster, in reply, expressed his appreciation of the Chairman's remarks. In the course of the many lectures and discussions before the Royal Society of Arts which he had attended he had always been impressed by the fact that the Society went direct to the source of the latest information, in approaching each subject. It had been a pleasure to him to convey in his paper some of the information collected through the experience of the Illuminating Engineering Society on industrial lighting. He was glad to see that the various speakers agreed as to the desirability of "Government by Consent." Experience showed that it was undesirable to attempt to bestow benefits by force, but in the case of industrial lighting people now recognised the need for regulations and would willingly accept them. The Report of. the Home Office Departmental Committee had already determined the amount of illumination desirable in the interests of safety and general convenience, and had arrived at the figure of 0·25 foot-candle, as a result of actual tests in a large number of factories, which ensured that the demand in this respect could readily be met. The instrument used in these experiments, about which several speakers had inquired, was the Holophane Lumeter, of which he had an example on exhibition. He was very glad indeed to hear from Dr. Legge, who had done so much to promote improvements in industrial illumination, that there was a prospect of a general statutory requirement of adequate lighting being inserted in the Factory Acts shortly. He agreed that the requirements should at present be of a general character. The requirements as regards the working illumination for various processes could be readily settled by conference between experts and representatives of the industries concerned. He had not meant to imply that the United States was in all respects in advance of this country, but rather that they had been in a fortunate position to profit by the experience of this country during the war. The methods in the United States were different. When he visited that country about six years ago the *New York Times* published a full page interview dealing with his suggestions regarding illumination, and industrial lighting in particular. At that time it was feared that owing to the independent legislation of the various States it would be difficult to carry through general requirements on industrial lighting. But in the ensuing six years six States had actually adopted legislation. When, however, this country adopted a statutory requirement of adequate lighting in factories, they would have the advantage that it applied to the whole country. As he had indicated in his paper there was a good prospect that industrial lighting would ultimately be dealt with on an international basis, and this country should take a leading part in action of this kind. In conclusion, Mr. Gaster thanked the other speakers for their kind references to the paper, and said that he was glad to observe that the views he had expressed met with general agreement.

The Chairman said the meeting largely appeared to agree with what Mr. Gaster had said; there had been very little criticism. Mr. Gaster's was one of those excellent practical papers, written by men who knew their subject thoroughly, which the Society was always anxious to receive. He proposed a very hearty vote of thanks to the author.

The vote of thanks was carried unanimously.

THE CERAMIC INDUSTRIES OF THE NETHERLANDS.

The ceramic industries of the Netherlands have been celebrated from the earliest times. In regard to raw material, no country is better fitted for the manufacture of earthenware. The valleys of the Rhine, Waal, Maas, Yssel, and their tributaries are lined with a stiff river clay, as "fat" as the potter can desire. The Maritime Provinces are covered with a layer of sea clay, deposited in ages past when the sea broke through the line of protecting sand dunes and flooded the low-lying land. The native clays cover a wide range of colours and properties suitable for pottery, brick, or tile making.

For clays, earths, mineral colours, and glazes that are lacking in the geological make-up of the country, the Netherlands, in ordinary times, have access to neighbouring countries which can supply them.

Pure kaolin is one of the earths lacking in the Netherlands and has to be imported, and the making of fine porcelain and china is handicapped for that reason.

The ceramic industries are well distributed over the Netherlands. Not merely the historic centres of the industry, but a number of towns less well-known are contributing to the country's output of fine and coarse earthenware. In 1918 there were sixty-nine establishments manufacturing earthenware and tiles. Of these nine were situated at Gouda, six at Utrecht, three at Delft, three at Arnhem, three at Bergen op Zoom, three at Maastricht, three at Nijmegen, two at Deventer,

two at Hazerswoude, two at Jutfaas, two at Leiderdorp, and two at Sneek.

The largest of these factories, situated at Maastricht, employed 2,000 workers. The combined number of employees in six other establishments was 755. Two of the principal factories, each employing 200 workers, used 90 horse-power each.

The most celebrated product of the Dutch ceramic industry is the blue-and-white delftware. Its origin goes back to the beginning of the seventeenth century and resulted from an effort to imitate the Chinese blue-and-white jars and plates which were just being introduced from the Orient. The industry flourished in the seventeenth century and well into the eighteenth. It extended from its original home at Delft to Arnhem, Amsterdam, Haarlem, The Hague, Nieuwer-Amstel, Oud-Loosdrecht, and Weesp. Delft alone boasted thirty earthenware factories in the palmy days of the industry. Vases, plates, tiles, and ornaments of all descriptions were produced in profusion and went to adorn the houses of the period. From the original blue-and-white the makers launched into a variety of colours and designs, finding their inspiration for the latter in the familiar scenes of Dutch daily life.

In the second half of the eighteenth century the market for delft declined, owing to the flooding of the European market with cheaper porcelains imported directly from the Orient, to the successful imitation of delftware by the French factories, and to the success of the English Wedgwood ware. The Dutch factories were gradually compelled to close down until, after 1850, only one of the establishments which had made the fame of delft survived. This factory, with the aid of the last of the tile painters who knew the old art, revived the industry in 1876. The success of their efforts to make blue-and-white delftware along the old designs has established the industry on a firm basis.

The characteristic shapes and designs of delftware are well-known even to the merest amateur collector of fine earthenware. The background is a glazed white, on which floral designs, birds, arabesques, and scenes of Dutch life are painted in a shade of blue known the world over by the name of delft blue. Less well known, but no less artistic, is the "coloured" delft, in which reds and greens are blended in harmonious designs. The remarkable feature of the older delft is the skilful way in which the impurities of the native clays have been concealed by a well-applied, white-lead glaze with a soft lustre. The modern makers of delftware have at their disposal the finest kaolins that can be imported. Modern delftware is made up into plates, dishes, tea sets, table services, vases, art tiles, tile portraits, bric-a-brac, and a host of ornamental objects.

The study of the characteristic makers' marks and designs of the antique delft is a science in itself. "Genuine" delft of the present day is considered to be the output of a single factory at Delft, the only present survivor of the thirty factories that flourished in that city in the palmy days of the industry. This factory has the credit of reviving an industry that was threatened with extinction. "Imitation" delft is made in the familiar blue-and-white designs at Gouda.

The Dutch factories, make, moreover, a considerable quantity and variety of the ordinary grades of chinaware for table services and other domestic use. Some of these follow the delft patterns; others imitate the Japanese and Chinese designs, while still others do not differ greatly from the styles sold in the United States.

Gouda earthenware has won for itself a reputation for its characteristic designs and colours. The principal material is a grey clay of domestic origin. Upon this are painted designs in brilliant reds, blues, yellows, greens and whites, frequently of a floral motif. It is principally made up into vases, jardinieres, platters, trays, humidors, ash trays, and ornamental plates. It is found in both the glazed and unglazed finish.

A pottery similar in colour effects to the Gouda, but more conventional in design, is made at Nordwijk. Katwijk earthenware has a bright yellow ground. At Utrecht the St. Lucas faience has become celebrated for its brilliant metallic glaze, which causes it to gleam like porcelain in certain lights, and in others to glow like gold or bronze.

At Makkum, in Friesland, the celebrated old "Makkum blue" ware is being successfully imitated. De Lemmer, in Friesland, has given its name to a type of uncoloured, glazed pottery of blue-and-yellow clay, with hand-carved, geometrical patterns.

A speciality of the potteries of Gouda is the manufacture of clay pipes. This industry dates back to 1637, and in its most prosperous days in the eighteenth century no less than 16,000 persons were employed in it. To-day there are seven factories at Gouda producing these pipes, and one at Weert. The largest of these at Gouda employs 150 workers and uses twenty horse-power.

Tile making is a branch of the ceramic industry in which the Hollanders have been especially successful. Tiles of all sorts are made, from roofing to flooring tiles, including tiles for purely decorative purposes. The latter are made in a wide range of colours and patterns, and are extensively used for decorating the outsides and insides of buildings. Entire fronts of buildings are decorated with pleasing patterns in tile work; for interior use they are found not merely in vestibules and around hearths, but covering entire walls. The newer office and factory buildings are extensively finished with attractive designs in tile.

In picture tiles the Dutch are excelled by none. The favourite designs are portraits, Dutch scenes, or remarkable reproductions of celebrated paintings in sepia or delft blue. Some of these are of single, large tiles; more often they are made up of individual tiles of about five inches square, with the sections of the design so merged that the lines

of division are scarcely noticeable. These are employed not only as house decorations built in the walls, but are frequently framed and hung up as pictures.

Floor and roofing tiles are generally produced in establishments making art pottery and porcelains. Roof and floor tiles were made by forty-six establishments in 1918, many of which are identical with the factories mentioned elsewhere as making earthenware and faïence. Koudekerk in Zeeland, led in the number of tile-making establishments with four, Maastricht followed with three, Utrecht with three, Woerden three, Alphen aan den Rijn three, Liederdorp, South Holland, two, Oudshoorn, South Holland, two, and Zuilen in Utrecht with two.

Roofing tiles of various materials are made in sixty-seven factories. Six of these establishments are in the appropriately named town of Tegelen, in Limburg, four are in Swalmen, Limburg, three in Winterswijk, in Gelderland, three in Reuver, Limburg, two in Leeuwarden, two in Utrecht, two in Woensdrecht, North Brabant, two in Alphen, South Holland, two in Belfield, Limburg, and two in Echt, Limburg. Many of the roofing-tile factories are also brickmaking establishments.

The characteristic roofing material in use in the Netherlands is the flat tile of red clay, with one edge bent up and the other bent down, forming an S-shaped shingle, whose edges interlock to exclude the rain. Other similar tiles are made of blue, or smoked, black clay. At Oegstgeest and Makkum the flat Frisian tiles are made.

A "fat" river clay of domestic origin furnishes the raw material for these tiles, which are subject nowadays to strong competition from similarly shaped tiles of cement, asbestos cement, and bent glass.

GENERAL NOTES.

The Agricultural Resources of Cyprus.—The first part of an interesting article on the "Agriculture of Cyprus," by Mr. W. Bovan, Director of Agriculture in the island, has recently appeared in the Bulletin of the Imperial Institute. The subjects dealt with include live stock, dairy produce, cereals, fruits, nuts, and vegetables. The Messaoria plain is the great corn-growing area, and in ancient times the island produced sufficient wheat to supply all the needs of its population, which then numbered over a million, the annual production amounting to about 10,000,000 bushels. At the present time, with a population of a little over a quarter of a million, only about 2,000,000 bushels of wheat are being produced, but the yield could be greatly increased by better methods of husbandry, by the use of improved implements for cultivating and reaping, and by the use of threshing machines. The methods practised have changed little for ages. The old wooden plough is still used, whilst the threshing-floors are practically identical with those of Biblical times, consisting merely of a levelled piece of ground, sometimes paved with flag-stones. A stout board, studded on the undersides with sharp flint stones (the tribulum of Virgil), is drawn over the spread-out sheaves by mules, donkeys, or oxen. Large quantities of barley are grown, the production in 1918 amounting to over 3,000,000 bushels. Most of this is used locally for feeding cattle, but some is exported to England for malting purposes. The cultivation of the grape-vine and the making of wines are important industries, and the celebrated Commandaria wine, which acquired great fame in the time of the Knights Templars, is still being produced and exported in limited quantities.

The Anhinga Fibre Industry.—The plant known as anhinga is a native of the State of Para, Brazil, and it is declared that this State alone is capable of producing 100,000 tons annually for export. The anhinga constitutes the raw material from which cellulose for the manufacture of linen paper is obtained. The fibres may also be transformed by a chemical process into an artificial cotton fibre. The fact that this fibre does not decay gives it an advantage over that obtained from analogous plants. The anhinga grows along the banks of all the rivers of Para, which have a slow current, permitting a soft bed of mud for their roots. In 1908 the Commercial Association of Para received a letter from a paper factory as to the possibilities of obtaining this fibre in large quantities, but at the time the Association was unable to find anyone to exploit the industry, because of the large and easily acquired profits afforded by the rubber industry. However, according to a statement published by the United States Department of Commerce, experiments were made in 1918 with excellent results, and those interested in the new industry have recommended that abandoned sugar-mills be fitted up for the treatment of the fibre. A mill already in operation is producing 600 kilos daily. The price of the fibre at Para is 300 to 350 reis per kilo. It is stated that the head of the Para State Chemical Laboratory has discovered a new process for dissolving the fibres, transforming them into very fine, white fibres, like cotton fibre of prime quality. Moreover, their structure is superior to that of the cotton fibre, since the lines are straight and parallel.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoon, at 4.30 p.m.:—

May 19.—John Somerville Highfield, M.Inst.C.E., M.I.E.E., W. R. Ormandy, D.Sc., and D. Northall-Laurie, F.I.C., "The Commercial Application of Electrical Osmosis."

ALAN A. CAMPBELL SWINTON, F.R.S., will preside.

The phenomena known as Electrical Endosmose and Cataphoresis, whereby matter in a very finely divided state is capable of being influenced by an electrical potential, has many applications in commercial processes.

The paper will deal more especially with the application of Electrical Osmosis as applied to the purification of clays, and will be illustrated by experiments and lantern slides.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

MAY 20.—BRIGADIER-GENERAL LORD MONTAGU OF BEAULIEU, K.C.I.E., C.S.I., "Roads and Transport in India." LIEUT.-GENERAL SIR HERBERT V. COX, K.C.B., K.C.M.G., C.S.I., Military Secretary, India Office, will preside.

Monday afternoon, at 4.30 p.m.:—

MAY 31.—ALBERT HOWARD, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." SIR ROBERT W. CARLYLE, K.C.S.I., C.I.E., will preside.

Friday afternoon, at 4.30 p.m.:—

JUNE 18.—SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

INDIAN AND COLONIAL SECTIONS.
(Joint Meetings.)

Friday afternoons, at 4.30 p.m.:—

MAY 28.—PROFESSOR WILLIAM A. BONE, D.Sc., Ph.D., F.R.S., "Lignite."

JUNE 4.—PROFESSOR SIR JOHN CADMAN, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire."

CANTOR LECTURES.

Monday evenings, at 8 p.m.:—

ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837." Three Lectures.

Syllabus.

LECTURE III.—MAY 17.—The third lecture is devoted to Sir John Soane, and traces his relations to the movement begun by Robert Adam and to the Greek and Mediæval revivals. Soane's ideas on architecture and decoration are discussed in relation to his more important works. In conclusion, it is pointed out that three-quarters of a century is covered by the work of Robert Adam and John Soane.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. A. T. Bolton, "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W. 4.30 p.m. The Right Rev. Bishop G. Forrest Browne, "Monumental Art in Early England, Caledonia, and Ireland."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Captain F. K. Ward, "The Valleys of Kham."

East India Association, 7A, Tothill-street, Westminster, S.W., 3.45 p.m. Mr. S. G. Roberts, "Tamil Proverbs: a Key to the Language and to the Mind of the People."

TUESDAY, MAY 18...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Mr. R. Stirling, "Air Lift System of Pumping Oil Wells."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "British Ethnology—The Invaders of England." (Lecture IV.)

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Sir Henry Howarth, "Buddhism in the Pacific."

Colonial Institute, Central Hall, Westminster, S.W., 3.30 p.m. Mr. L. W. G. Malcolm, "The Cameroons."

WEDNESDAY, MAY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Messrs. J. S. Highfield, Dr. W. R. Ormandy, and D. Northall-Laurie, "The Commercial Application of Electrical Osmosis."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Dr. G. Taylor, "Agricultural Climatology of Australia." 2. Messrs. J. E. Clark and H. B. Adames, "Report on the Phenological Observations for 1919."

Geological Society, Burlington House, W., 5.30 p.m.

THURSDAY, MAY 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Brigadier-General Lord Montagu of Beaulieu, "Roads and Transport in India."

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. P. Graves, "Welsh and Irish Folk Song." (Lecture II.)

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 5.30 p.m. Annual General Meeting.

Numismatic Society, 22, Russell-square, W.C., 6 p.m.

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 6 p.m. Dr. S. Ahmad Khan, "The Development of Modern Educational Institutions in India." (Lecture III.)

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. G. Rigg, "Roasting and Lead-Smelting Practice at the Port Pirie (S.A.) Plant of the Broken Hill Associated Smelters Proprietary, Ltd." 2. Captain H. Tatham, "Tunnelling in the Sand Dunes of the Belgian Coast."

FRIDAY, MAY 21...Royal Institution, Albemarle-street, W., 9 p.m. Professor J. A. Fleming, "The Thermionic Valve in Wireless Telegraphy and Telephony."

Philological Society, University College, W.C., 5.30 p.m. Mr. C. T. Onions, Dictionary Evening.

SATURDAY, MAY 22...Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. Harrison, "The Reaction and the Critics of the Positivist School of Thought."

Journal of the Royal Society of Arts.

No. 3,522. VOL. LXVIII.

FRIDAY, MAY 21, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

POSTPONED CANTOR LECTURE.

The third lecture of the course on "Aluminium and its Alloys," by Dr. Walter Rosenhain, F.R.S., Superintendent of the Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, which was postponed from April 26th in consequence of the sudden illness of the lecturer, will be delivered on Monday, June 7th, at 8 p.m.

POSTPONEMENT OF THE PAPER ON "LIGNITE."

Professor William A. Bone, D.Sc., Ph.D., F.R.S., has been unavoidably compelled to postpone until next session the reading of his paper on "Lignite," which had been announced for Friday, the 28th inst.

CANTOR LECTURE.

On Monday evening, May 17th, Mr. Arthur Thomas Bolton, F.R.I.B.A., F.S.A., Curator, Soane Museum, delivered the third and final lecture of his course on "The Decoration and Architecture of Robert Adam and Sir John Soane, 1758–1837."

On the motion of the Chairman, seconded by Mr. F. H. Hebblethwaite, a cordial vote of thanks was accorded to Mr. Bolton for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, May 20th; Lieut.-General Sir Herbert V. Cox, K.C.B., K.C.M.G., C.S.I., Military Secretary, India Office, in the chair. A paper on "Roads and Motor Transport in India" was read by Brigadier-General Lord Montagu of Beaulieu, K.C.I.E., C.S.I.

The paper and discussion will be published in a subsequent number of the *Journal.*

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 19th; Mr. Alan A. Campbell Swinton, F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Baines, Hubert, C.B.E., London.
Hakes, James A., Sunbury-on-Thames.
Hartigan, Lieut.-Colonel Marcus Michael, C.M.G., D.S.O., Ashford, Middlesex.
Hosken, Richard, Assoc.M.Inst.C.E., M.I.M.E., London.
Osborne, F. B., London.
Rutherford, Henry, London.
Sarasasna, Lieut.-Colonel Bra, Bangkok, Siam.
Smith, George, London.
Stuart, John Matthew Blackwood, B.A., Enniskillen, Ireland.
Tarrant, Ernest Frederick, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bixby, William Keeney, M.A., LL.D., St. Louis, Missouri, U.S.A.
Bowden, John, Chorlton-cum-Hardy, Manchester.
Christie, Edward William, London.
Cleveland-Stevens, Edward Carnegie, M.A., D.Sc. (Econ.), London.
Cravath, Paul D., A.M., LL.B., New York City, U.S.A.
Davies, Thomas Bertram, Durban, Natal, South Africa.
Grieve, Norman William, London.
Gross, Alexander, F.R.G.S., London.
Kerr, Henry Farquharson, New York City, U.S.A.
Norrington, George Frederick, Wilmslow, Cheshire.
Perry, Mrs. Thos. Sergeant, Boston, Mass., U.S.A.

Reed, Harry E., Swansea.
Richards, Captain James Charles, Assoc.Inst.N.A., Bombay, India.
Summers, Albert Victor, Cheadle Hulme, Cheshire.
Thomas, David Idwal, M.Inst.M.E., Porth, Wales.

A paper was read on "The Commercial Application of Electrical Osmosis" by Messrs. JOHN SOMERVILLE HIGHFIELD, M.Inst.C.E., M.I.E.E., W. R. ORMANDY, D.Sc., and D. NORTHALL-LAURIE, F.I.C.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, April 15th, 1920; THE RIGHT HON. EDWIN S. MONTAGU, M.P., Secretary of State for India, in the chair.

THE CHAIRMAN, in opening the meeting, said he did not propose to commit the impertinence of introducing Sir George Buchanan, because his reputation was established amongst all those interested in engineering works in India. In 1914 Sir George read to the Society by deputy a paper on "The Port and City of Rangoon," and Lord Inchcape, who presided, expressed the opinion that Sir George had saved that port by the great work he had carried out. It was true to say that his work there was remarkable from the point of view of those interested in Indian finance, in that he did everything he wished to do inside his estimate—a very notable performance. He felt sure that after his work in India and in Mesopotamia Sir George could rely upon an interested audience with a hungry appetite for what he was going to say.

The paper read was—

THE PORTS OF INDIA: THEIR ADMINISTRATION AND DEVELOPMENT.

By SIR GEORGE BUCHANAN, K.C.I.E.

There is so much to be said on the subject that I have chosen for my paper, that it will be difficult adequately to deal with the matter and yet keep within the required limits of space and time.

For many years I have been an earnest student of port affairs, my studies not having been confined to Indian ports, and I came to the conclusion some years ago that unless there was an improvement in the existing method of administering and developing ports in India, they would be unable to keep pace with the requirements of an ever-increasing trade.

My reason for this view is that the immense importance of terminal facilities has not been sufficiently recognised in India, and ports are usually coupled with municipalities and district councils and looked upon as purely local affairs, regardless of the fact that whilst the evil a badly managed municipality does is practically confined to itself, a badly administered and developed port can cripple a whole province or even provinces.

The port of Karachi, for instance, is more the port of the Punjab than it is of Sind, and the port of Calcutta serves half the provinces of India.

It seems hardly credible that India, with a coast-line of over 4,500 miles, an area of over 1,800,000 square miles, a population of 350,000,000, and a trade the total value of which before the war exceeded £300,000,000 sterling, possesses only six ports with any pretensions to the name.

The entire west coast of India is served by Karachi and Bombay, the east coast by Madras, Calcutta, and Chittagong, and Burma by Rangoon, whilst as indicating the physical aspect of the country, Bombay, Karachi, and Madras are seaports, and Calcutta, Chittagong, and Rangoon river-ports.

There are a certain number of minor ports—viz., Porbandar and Veraval between Karachi and Bombay; the Portuguese port of Marmagao, south of Bombay; Mangalore, Calicut, Cochin, and Quilon on the Malabar Coast between Bombay and Cape Comorin; Tuticorin, and Cocanada, with Vizagapatam in course of execution, on the east coast; and Akyab, Bassein, Moulmein, Tavoy, and Mergui on the Burma coast. All the minor ports are, however, undeveloped, and principally used for the coasting trade.

The year before the war, the six major ports had an aggregate revenue of 368 lakhs of rupees, an expenditure of 327½ lakhs, and a capital debt of 3,000 lakhs; 16,150,000 tons of shipping entered the ports during the year, and the aggregate value of trade was 51,289 lakhs of rupees, whilst taken proportionately Bombay and Calcutta headed the list; then came Karachi and Rangoon, followed a long way after by Madras and Chittagong.

I give these figures to show by their magnitude that the ports of India are worthy of development and encouragement.

In order to form some idea of the problems dealt with under the heads Port Administration and Development, I will briefly analyse the

requirements of a modern port, after which I will describe and discuss the leading characteristics of the major ports of India and give my views on port administration and port development.

Port Requirements.

The object of a Port Administration is to benefit the community at large and the trade of the country, bearing in mind that business follows port facilities.

The problem of port development necessitates as a preliminary step a study of actual local conditions at the port itself, but there are certain facilities and equipments that are essential for any first-class port. These primary requirements are: (1) Facility for prompt despatch of steamers, (2) ample storage accommodation for goods, (3) adequate transport facilities behind the port, the first of these being largely contingent on the extent of the second and third. The growth in the size of ships has been very great in the last fifty years, and the necessity for adequate port accommodation has increased proportionately. The greater the size of vessels, the more economically can they be run, owing to the fact that the consumption of fuel is *pro rata* less and the voyages required fewer, and it has been shown that if the draught be increased proportionately to the increase in other dimensions, the cargo can be carried at a steadily decreasing cost as the size increases.

In days gone by, when ships were comparatively inexpensive, they were built to suit the ports which were considered to be costly. The situation is now reversed, and if the authorities at a port wish to secure or hold the trade, they must be prepared to march with the times and adapt their ports to the ships. And the ports that are most efficient are those that have kept their facilities ahead of actual requirements. Despatch, despatch, and again despatch is what the port authority has to look to, and the shipowner with a valuable vessel in which an enormous sum is capitalised, and with constant large current expenses, naturally prefers a port which gives good despatch. From the port authority's point of view, to make a port popular with shipowners means to make it a port to which it is profitable to come, and a port to which a low freight will be accepted.

What constitutes adequate facilities for the prompt despatch of steamers and storage of goods, is a question that every port must answer for itself, but, as a rule, it resolves itself into the following:—

1. A deep, well-buoyed and well-lighted channel, extending from the sea to the entrance to docks or wharves.
2. Sufficient deep-water wharf accommodation, either inside docks or alongside a river or harbour front.
3. An abundance of cranes or conveyors and ample shed and warehouse room.
4. Ample railway and road connections to the interior, and where there is inland navigation, facilities for transhipment to river steamers, when and where required.

The rate of discharge from the ship is controlled by the ability to give clearance on shore, and the capacity of ships has now become so great that the accommodation in the sheds and the ability of consignees to take delivery are taxed to their utmost, in endeavouring to keep pace with the actual discharging operations.

The above is a summary of what may be called the working requirements of a port, and of equal importance are the financial requirements; the main considerations governing the financial working of a port being: (*a*) that the expenditure should not exceed the revenue, *i.e.*, that it should never be necessary to borrow from capital to pay revenue charges; (*b*) that capital charges should be so adjusted as not to burden unduly either the present generation or posterity; (*c*) that rates, dues, and charges should be uncomplicated, easily collected and levied so that there is an even distribution of taxation, no one individual or portion of the community being taxed to the benefit of another which pays nothing; (*d*) that port dues, rates, and charges should be liable to as few alterations as possible.

The ratio between tonnage dues on vessels and rates on goods has to be considered, and above all it must be remembered that there is a limit to the capacity for payment by both shipowners and merchants.

From the above it will be seen that the control of a large modern port is no sinecure, and requires special knowledge and continual study on the part of the members of the port authority.

Description of the Ports.

Bombay.—Bombay is the premier port in India, and has been fortunate in having had for generations a definite policy, and engineers in charge of the port works who had been specially trained as harbour and dock engineers in the United Kingdom. The Port Trust was created in 1873, when the property of the Elphinstone Reclamation Company was purchased by Government for the sum of 186 lakhs of rupees, and their engineer, Thomas Ormiston,

was the first engineer to the Port Trust. The Prince's Dock, begun in 1875 and completed in 1880, has a basin accommodation of 30 acres, and a depth on the sill below H.W.O.S.T. of 28·25 ft., and below H.W.O.N.T. of 25 ft. In 1885 the construction of the Victoria Dock was undertaken, and completed in 1888, with a basin of 25 acres and a depth on the sill two feet lower than the Prince's Dock.

In 1905, the Alexandra Dock was begun, and it was opened by the Viceroy on March 21st, 1914. This dock has an area of 49½ acres, with a depth on the sill of 37·25 ft. at H.W.O.S.T. and 34 ft. at H.W.O.N.T., or 9 ft. lower than the Prince's Dock.

The Prince's and Victoria Docks can accommodate 27 vessels of lengths ranging from 300 ft. to 500 ft.; the Alexandra Dock provides for an additional 17 vessels of 500 ft. to 520 ft., and another berth for a vessel of 425 ft. has been provided outside the dock for mail steamers. The docks are well equipped with sheds, warehouses, cranes, etc., and in recent years 580 acres of land have been reclaimed on the foreshore north of the docks, which is to be utilised for the cotton, grain and manganese ore trade. The port of Bombay is served by the Great India Peninsula and Bombay Baroda and Central India Railways, through a Port Trust railway, which traverses the dock estate. Financially, Bombay port is in a strong position, its trade is assured, and the port revenue is derived from so many sources that a failure in any one branch of the trade would not materially affect the financial situation, especially with the large revenue reserve fund. The whole of the foreshore is owned by the port, and a noteworthy feature in the accounts is the large amount received from ground rents.

The Port Trustees are now discussing further dock extensions either in front of the Alexandra Dock or up the harbour in the direction of Trombay. To add to the present traffic congestion by building another dock in the vicinity of the present docks would, I consider, be a great mistake, and obviously the port must expand in the Trombay direction, but whether it is necessary or even desirable to build a dock is matter for consideration.

The Trustees have got so into the habit of building docks that they are, perhaps naturally, averse to consider alternatives, but the site appears on the face of it to be particularly favourable to the construction of a large deep-water wharf. Modern dredgers could without difficulty cut a deep channel right up the harbour, and by using the material dredged for reclamation purposes, a magnificent export yard with a deep-water wharf, capable of great expansion, could be constructed at a considerably less cost than would be necessary for a dock, and in these days of dear money a saving on capital expenditure is not to be neglected.

It is also of the first importance to deepen the water in the main entrance channel to Bombay Port, and at the anchorage, and all the material dredged could be used for reclamation purposes, either for the port, or the extension and improvement of the town. At present, there is only 22 ft. to 26 ft. below the mean of lowest spring tides within a mile of the docks, and a depth of 32 ft. in the entrance channel at high water of neap tides, the result being that steamers of ordinary draught are delayed for want of water, a case in point being a recent mail steamer from Bombay to London, drawing only 27½ ft., which had to postpone her scheduled time of sailing by several hours because there was insufficient water in the main channel. The time lost at Bombay was the direct cause of several more hours being lost at Suez and Port Said, the result being that mails and passengers arrived in London twenty-four hours late.

Such an incident in a port which considers itself in the first rank, is, to say the least of it, most unsatisfactory. The Port of Bombay requires very careful handling in the near future, a great deal of money will have to be spent, and it behoves the authorities to see that a correct policy of expansion is adopted.

Karachi.—Karachi was occupied by the British in 1839, and at that time the port was a shallow, more or less land-locked lagoon. Up to the year 1873, the port was merely an anchorage, and all exports and imports by seagoing steamers had to be shipped and landed by means of country boats, but in 1870 was begun, and in 1873 finished, the Manora breakwater which protects the harbour entrance from the south-west monsoon, and the real development of the port may be said to have started from that date.

The Port Trust was created in 1886, at which time the port had accommodation for one seagoing steamer at a wharf, and eleven in the stream.

The port now possesses a continuous line of wharfage, 8,600 ft. in length, containing seventeen steamer berths, equipped with cranes. There is also a wharf 1,824 ft. in length for the country craft trade, and one 325 ft. long for

the coasting steamer trade, a bulk oil pier, a heavy lift pier, and an import yard separated from the wharves, to which imports are conveyed by rail, and a produce yard originally built for the use of merchants wishing to store grain prior to shipment.

There are also twenty moorings in the stream for ocean-going steamers.

The steamer wharves have a maximum depth of water alongside of 28 ft. at H.W.O.S.T., which it is proposed to increase to 34 ft., and there is a minimum depth in the approach channel of 32 ft. 6 ins. at H.W.O.N.T.

Communication with the interior is by the North-Western Railway, which traverses the Punjab in various directions and has lines running through Baluchistan to the frontiers of Afghanistan and Persia, and to the North-West Frontier Province.

The Jodhpur-Bikaner Railway, metre gauge, starts at Hyderabad and serves Rajputana, one branch going to Delhi; but for some obscure reason is not permitted to run into Karachi from Hyderabad. A broad-gauge line from Karachi to Jhansi, connecting with the Great India Peninsula to Cawnpore or Gwalior, and thence to Cawnpore, is clearly indicated, and will presumably be built in the near future.

The Port of Karachi depends for its prosperity almost entirely on the grain trade, and a failure in the monsoon or other disturbing factor at once causes a serious fall in the revenue.

The greatest total export in one year was 3,000,000 tons of wheat, barley, maize, gram, and a certain quantity of military stores in 1917-1918, and the greatest export of wheat was 1,380,000 tons in 1904-1905. Imports vary from 700,000 to 1,000,000 tons per annum, and on an average the total quantity of export and import may be taken at 2,500,000 tons to 3,000,000 tons per annum, from which the Port Trustees derive a revenue of approximately Rs. 1½ per ton.

The financial position is not particularly strong. The total revenue varies from 35 to 60 lakhs, and the Port Trustees consider 50 lakhs as a safe average to depend upon for the next ten years. The expenditure, except in an abnormal year, runs the revenue very close. The total debt is 257 lakhs, and the annual payment in interest and sinking fund 15½ lakhs; the revenue reserve is 36½ lakhs. New schemes are under consideration, estimated to cost 250 lakhs, which, at 8 per cent. for interest and sinking fund, will add another 20 lakhs to the revenue expenditure, an amount it will be obviously difficult to meet unless rates and dues are greatly increased or there is a very material increase in trade.

At present there are neither storage sheds for grain, nor grain elevators, and during the busy season some six thousand wagons of the North-Western Railway are confined to the railway district, owing to the difficulty in disposing promptly of their contents. One solution of the problem is the installation of grain elevators at the port and in the grain producing districts, in which case any great scheme of wharf extension might safely be postponed for the time being. The declared policy of the Port Trust is, however, to defer action in the matter of elevators until there is an actual practical demand from either the trade or the North-Western Railway.

The trade are at present quite satisfied with the existing state of affairs, and will continue using railway wagons as warehouses so long as they are available, but the railway is getting restive. A committee appointed by the Government of India in 1909 reported generally in favour of elevators, and there seems little doubt that with the certain expansion of the Karachi wheat export trade, elevators will ultimately be required, in order to bring Karachi into line with other grain-exporting ports.

It will be matter for regret if, when that time comes, the Port Trust are so committed to the old system and have spent so much on new wharves, that it will then be too late for the change.

The fact is that the whole future of Karachi requires the deepest consideration from the Imperial point of view, as it must some day be a very large port, and in addition to the yearly increasing export trade from Sind and the Punjab, Karachi is marked out as the chief Indian port for the trade with Mesopotamia and Persia. The people of Karachi are disposed to think that it might even now be a much greater port had it not been for jealousy on the part of Bombay, who looked upon Karachi as a dangerous rival. I doubt if such was ever the case to any material extent. The development of Karachi has been limited to the export requirements of the Punjab and Sind, and every extension of the irrigation systems in these provinces has led to increased exports, with demands for increased port accommodation. Karachi is 200 miles nearer to Aden than Bombay, and when a direct broad gauge line is constructed, Karachi will be a hundred miles nearer Delhi than Bombay, and therefore considers that she has a claim to

be the principal Indian port for mails and passengers from Europe. It must, however, be remembered that Karachi does not possess even the amenities of Bombay, and that consideration must be shown to mails and passengers to and from Bombay and Calcutta. I should therefore be surprised if Karachi could ever put up a strong enough case to supplant Bombay as a terminus for mails and passengers to and from Europe.

In my judgment Karachi is now at a most critical stage of its existence, requiring a wise, far-seeing policy on correct lines, as mistakes made to-day may have a tremendous effect upon the future.

Calcutta.—A writer, in 1853, observed: "Quays for the approach and use of shipping do not exist in Calcutta, neither are there any fixed landing stages, jetties or floating piers, partly perhaps owing to the questionable nature of riverside foundations, and the objection to attaching vessels to a quay wall during the bore, and also from a general absence of energy and enterprise in the local commercial interest, a general and indefinite idea being current that a comprehensive plan would some day be devised for securing greater advantages." Yet another writer, in 1882, said: "Up to the year 1868 the history of port improvements in the sense of appliances to facilitate the trade of the port is a history of projects and commissions of inquiry thereon. Much was proposed but nothing done." These writers of the past point a moral which it would not be difficult to apply at the present day, because it is an undoubted fact that Calcutta which, from its geographical situation at the head of the Gangetic Plain, should be one of the first ports in the world, has not kept up with the requirements of trade and navigation, and is one of the most backward ports in the East. In 1866, an Act was passed appointing the municipal authorities trustees for carrying out port improvement works, but by 1870, when the Port Trust was created, the total accommodation for seagoing vessels consisted of four small screw-pile jetties equipped with cranes and sheds; by 1882 there were eight jetties with a total length of wharf of 3,050 ft. and 230,000 square ft. of shed accommodation, and a definite impetus having been given, the question of constructing a wet dock was brought forward. For many years the building of a wet dock had been discussed in the abstract, and sites proposed at Tolly's Nullah, Diamond Harbour, Akra and Kidderpore. The latter site was finally adopted and the work begun in 1884. The first ship entered the dock on June 21st, 1892, but for a very considerable time thereafter the dock was empty, as the owners of vessels refused to use the dock, preferring the riverside jetties, and the consignees of imports refused to take delivery of their goods so far from their warehouses. By 1894 these prejudices had been to a certain extent overcome, as trade was increasing rapidly and great congestion obtained at the jetties. Ultimately the Port Trustees passed an order confining the use of the jetties to imports and the docks to exports. At the present time the Port Commissioners possess at the jetties nine berths for seagoing vessels with a frontage of 4,735 ft. and additional berths are under construction. Kidderpore Docks contain seventeen berths for general produce, and ten coal berths, and an additional berth for general produce has been recently constructed. The Commissioners also possess extensive sheds and warehouses for both exports and imports, a tea warehouse, inland vessels wharves and a petroleum wharf at Budge-Budge, and the Port Trust railway running between Cossipore and the Kidderpore docks on the left banks, and Howrah and Shalimar on the right bank, has an aggregate length of about sixteen miles.

Calcutta is served by the East Indian Railway, the Bengal-Nagpur Railway, the Eastern Bengal Railway, and by several lines of inland steamers. The East Indian and Bengal-Nagpur Railways have their termini at Howrah, on the opposite side of the river to Calcutta, but they get a connection to the docks by way of Naihati, where there is a bridge across the Hooghly and a connection with the Eastern Bengal Railway.

The correct policy in port development is always to have facilities a little in advance of necessities, and between 1895 and 1900 Calcutta was fairly up to date, but when the time came to make another push forward the Commissioners, as in earlier days, had resort to "Commissions of Inquiries."

In 1900–1 a Committee was appointed by Government to consider how the management of the port could be improved, especially with reference to economy and efficiency. The report therefore dealt largely with administrative details; the Committee did, however, propose various additional facilities for the import trade at the jetties, but expressed the opinion that no large capital expenditure was necessary in the near future at the docks, as their capacity was sufficient for all probable requirements and they were capable of gradual extension.

The Commissioners were thus lulled into a

feeling of security, and whilst the other large ports of India were busy with extensions and improvements Calcutta remained with folded hands, and was only awakened from its sleep by the clamour on the part of the public for facilities for meeting the rapidly increasing demands of trade, with the result that in 1913 another Committee was appointed by Government to deal comprehensively with the whole question of the development of the port of Calcutta.

The Committee issued its report on March 19th, 1914, and recommended approval to a very large dock extension scheme and to a number of minor improvements. Unfortunately the great war broke out in August, 1914, causing a postponement of all development schemes, and Calcutta is only now picking up the threads and making a fresh start. The Port Commissioners will have, however, to pay dearly for their lack of foresight, as the docks will cost twice the pre-war price, and at the same time the Commissioners will have to pay 50 per cent. more in interest on loans.

The trade of the port will no doubt improve rapidly now that the war is over, but the financial position leaves much to be desired. Even before the war the ordinary expenditure exceeded the ordinary revenue, and in 1918 there would have been a deficit of 18 lakhs of rupees, or, at Rs. 10 to the po nd, £180,000, had it not been for a war surtax amounting to 52 lakhs, or over half a million pounds. The revenue reserve is only 46 lakhs, compared with 90 lakhs at Bombay, whilst expenditure on interest and sinking fund, already amounting to 60 lakhs, will be vastly added to by the new dock scheme now in hand.

Apart from the provision of dock accommodation, Calcutta cannot in the future maintain its position as a great port unless measures are taken to improve the river.

The 1914 Committee recognised this basic fact, and in their report made the following observations :—

"(*a*) The prosperity of the port will be largely dependent on its capacity to receive the size and draught of vessels which can navigate the Suez Canal. This will involve a very considerable advance in the measure of improvement in the river approaches which has been obtained up to the present time.

"(*b*) The interests involved are of such magnitude, and in particular the capital sunk in the port will be so much increased by the dock extension that it would be unwise to rest satisfied with a more or less empirical system of dredging as the whole means of river improvement. On the contrary, the whole question should be again investigated and decided on at an early date by the port authorities.

"(*c*) The physical and economical aspects of that improvement are surrounded with problems of a very complex character, which can only be satisfactorily determined by such a consensus of the expert opinion available as will carry public confidence with it and enable the improvement to be undertaken with the greatest promise of success."

The Committee further pointed out that there were few modern ports of importance which had not found themselves compelled to face heavy expenditure in the improvement of access for vessels of deep draught, and they urged that the inquiry should not be postponed, as the problem was likely to be of increasing urgency.

In a paper of this description there is not space to go into details, but, broadly, the position is that for general everyday work the condition of the river limits the draught of vessels entering and leaving the port to 26 to 27 ft., but at spring tides it is possible to accommodate vessels up to 30 ft. The shoals are not only inconvenient but are a positive source of danger, and only last year a large steamer, laden with 6,200 tons of rice, grounded on a shoal, broke her back, and was abandoned a total loss.

There is no overwhelming difficulty in deepening and improving the river, nor is it even necessary to carry out at once, and at vast expense, an heroic scheme of training works, but the Port Commissioners appear to prefer a *laissez faire* policy, regardless of the fact that new docks and wharves are mere useless extravagances if the river is not deep enough to convey large vessels from and to the sea every day of the year.

The Port Commissioners as a body can hardly be held blameless for the backward state of the port and river, but the lack of initiative and inability to frame a definite policy or even to take competent advice is to a certain extent due to defects in administration.

In 1901, when the offices of vice-chairman and chief engineer were divided into two appointments, the vice-chairman became the chief executive officer of the Trust but still had as his senior an official chairman who was a Government official, and this led to "dual control," which has from time immemorial been fatal to efficiency. It may be argued that there are many ports at home and elsewhere with a general manager and an official chairman, but for various reasons this argument does not apply to India; and the fact remains that the successful ports of India owe their success largely to the

efforts of individuals who held the combined office of chairman and chief executive officer, and were able to frame a policy and carry it through. The failure to effect river improvement works can also be set down to faulty administration, inasmuch as the work is entrusted on the Hooghly to marine officers instead of to engineers. The illusion that because a dredger is a vessel it must necessarily be managed by a marine officer, and that because a marine officer navigates a vessel he must also be a student in problems of hydraulics, is one that hardly exists out of India, and it has led to many difficulties wherever this custom obtains. On rivers such as the Thames, Mersey, and Tyne, and on the American rivers, dredgers form part of the engineering equipment of the port, and are designed and controlled by the engineering department. All works connected with river improvement are also regarded as pre-eminently appertaining to the engineer, indeed, it is recognised that amongst the many matters which engage the attention of the engineer there are none more difficult than those which relate to the subject of rivers and stream control.

What is now urgently required at Calcutta is administrative reform, which can be best attained by the appointment of a whole-time chairman of great experience and ability (salary being of no importance if the right man can be obtained), assisted by a staff of experts in dock engineering, river engineering, and traffic management, and with efficient administration would come a healthier financial condition.

Rangoon.—As from 1901 to 1915, when I was sent to Mesopotamia, I held the offices of Chairman, Chief Executive Officer, and Chief Engineer of the Port of Rangoon, it is difficult for me either to praise or blame. I will, however, point out briefly the history of the port and state what, in my opinion, should be its policy in the future.

Between 80 and 90 per cent. of the whole of the trade of Burma passes through the port of Rangoon, which is situated on the Rangoon River, about thirty-nine miles from the sea. Up to the year 1879 the port was controlled by various bodies and individuals, but in that year a Port Trust was created, port limits defined, and the control and maintenance of the port vested in the Port Commissioners. The principal export is rice, and from earliest days this trade has been conducted in the stream, a convenient practice, as the millowners all possessed a river frontage to their mills, and the rice was conveyed in cargo boats to vessels moored in the river. This procedure has not been interfered with, it is satisfactory to all parties, and the river takes the place of an expensive wet dock. Adequate moorings, both swinging and fixed, have, however, been provided for vessels, and various regulations made for the proper control of the cargo boats.

In the absence of a dock the import trade required deep-water wharves along which sea-going vessels could lie and discharge their cargoes, and sheds and warehouses into which goods could be landed and stored. These have been provided to an extent sufficient to give a berth to every steamer requiring accommodation whether for the foreign or coasting trade. An important trade at Rangoon is that carried on by the river steamers which penetrate, *via* the Irrawaddy River, to nearly every part of Burma, and extensive accommodation in the shape of floating pontoon stages, sheds, and warehouses has been provided above the deep-water wharves. The port is fed by the Burma Railways Co. in addition to the river steamers, between which a wholesome competition exists.

Between 1900 and 1914 the revenue of the port increased from 12 lakhs to 52 lakhs, the net registered tonnage of shipping entering the port from 1,500,000 to 3,000,000, and the value of trade from 2,326 lakhs to 5,775 lakhs.

Like other river ports, Rangoon has had its troubles with its line of communication to the sea, the chief of which necessitated the building of a training wall two miles long at a cost of a million pounds in order to prevent the river changing its course and leaving Rangoon high and dry. This work was successfully accomplished, and a problem now in course of solution is the cutting of a channel through a shoal at the junction of three rivers a mile or so below the port, which prevents steamers of heavy draught having access at all times to the wharves and moorings.

The Port Commissioners are aiming at a 30-ft. channel from the sea to Rangoon at ordinary tides, and although the work will involve a large expenditure, and is, to a certain extent, experimental, they are prepared to take the risk.

In my opinion, Rangoon as a port is still in its infancy, and the Port Commissioners need to be very far-seeing and courageous or they will fail to keep pace with the times. Burma is a country with vast potentialities which are only beginning to be recognised, its mineral wealth and forests are almost untapped, and the agricultural possibilities, particularly in sugar, are enormous. The port cannot expect to continue

to conduct all its export trade in the stream, as in the near future goods for export by the thousands of tons will come down from Upper Burma by rail. A large, well-equipped export wharf is required, a site for which has already been selected; additions and extensions to the import wharves and river-steamer wharves, more warehouses, and a dry dock, are other works which are indicated.

Chittagong.—Chittagong was an important place so long ago as the sixteenth century, when it was controlled by the Portuguese, but very little was done to the port, and before the advent of the Assam-Bengal Railway there were practically no land communications with the interior. The principal export trade was jute, which was conveyed in sailing brigs from Narayanganj and transhipped at Chittagong into seagoing vessels.

There was no trade in tea, and a comparatively small import trade.

In 1887 a Port Trust was created, but the mere creation of a Port Trust with powers under an Act of the Legislature does not make a port, and the trustees began their career with neither money, credit, equipment, foreshore land, nor experience of port administration. Up to the year 1892 there was no thought of developing the port, and although the Commissioners had powers under their Act to acquire land and to construct wharves they preferred to give authority to private individuals to erect jetties, and were commended by the local Government for keeping out of debt. In 1892, when the Assam-Bengal Railway with its terminus at Chittagong was under construction, the Port Commissioners awoke to the fact that they had no foreshore land on which to build seagoing jetties, and no money either to purchase land or to build jetties. Thereupon followed a lengthy correspondence with Government and the appointment of committees, sub-committees, and special experts. The Government of India said it was obviously the duty of the Port Commissioners to build jetties and otherwise provide all facilities for the landing and shipping of goods, and the Port Commissioners were ordered to carry out the functions for which they had been created. But finally, as the Port Commissioners had no money and Government declined to assist them either by grant or loan, the railway company were empowered to construct and manage such wharves as were necessary to provide terminal facilities for their traffic. One step led to another, and the railway company have now been given entire control of the port and the river.

The history of Chittagong port is a striking example of how things ought not to be done, and an argument in favour of some measure of Imperial control of Indian ports.

The Chittagong River has, through neglect, fallen into a shocking state, and an expenditure of 100 lakhs, together with a considerable recurring expenditure, will be necessary to make it navigable at all times for large vessels, and now that the Chittagong-Akyab Railway is to be built it is for consideration whether the railway would not do well to make Akyab the chief marine terminus, as an excellent port can be made there at comparatively little cost.

Madras.—Madras is the only British port, with any pretensions to the name, between Bombay on the west coast and Calcutta on the east coast of India, and it is perhaps open to question whether it was wise to attempt the construction of a large port in that particular locality, exposed as it is to the full force of the south-west monsoon.

Proposals for an artificial harbour were first made in 1868, and were sanctioned by the Secretary of State for India in 1875. The works were begun in 1877, and in 1881 the breakwaters were severely damaged by a cyclone, and it was not until 1895 that the harbour, on its original plan, was completed. The harbour was not, however, a success, as so far from being a refuge, there was so much disturbance inside the harbour that on the approach of a storm shipmasters preferred to go outside to the open sea.

Experts were called in, and discussed for many years whether the entrance for shipping ought to be on the eastern side, facing the sea, or in the north-east corner under a sheltering arm, and finally it was decided to adopt the latter course, and to close the existing entrance. This work was completed about the year 1910, and has proved fairly successful, but although the harbour is now smooth enough for working cargo out of lighters alongside ships and piers in ordinary weather, in the event of a cyclone all commanders of vessels are recommended by the port authorities to go out to sea as soon as the great danger signal is exhibited on the port flagstaff. The artificial harbour is, in fact, as described by Sir Francis Spring, the late Chairman, "a challenge flaunted in the face of Nature, which in revenge gets in a home thrust at intervals."

In other respects, between 1904 and the present time, the harbour has been completely remodelled and provided with modern equipment, deep-

water wharves, sheds, warehouses, and all the appliances of a modern port.

The total trade of the port is 139 lakhs of rupees, and the revenue and expenditure are in the neighbourhood of Rs. 16 lakhs and Rs. 14 lakhs respectively, whilst the total tonnage handled amounts to between 600,000 and 700,000 tons per annum.

Madras will never be a great port, and may even lose a portion of its trade when cheaper ports are opened up in the vicinity.

The Ports and the War.

The effect of the war on the ports is shown in the tables annexed to this paper, from which it will be seen that the western ports of Bombay and Karachi rather increased their trade than otherwise; Calcutta was seriously hit, and Rangoon was hardly affected. The reason for the prosperity of Bombay and Karachi was, that they were the two ports from which were shipped India's contribution to the war, in the shape of men, materials, and foodstuffs, and were the base depots for the Mesopotamia and East Africa campaigns.

Owing to the shortage of tonnage, exports from Calcutta were, to a great extent, railed from Calcutta to Bombay, but there being no rail communication with Burma, Rangoon had to be supplied with tonnage for the shipment of the rice crop.

On the whole, however, it is matter for congratulation and wonder that the ports of India suffered so little from the war, and that, thanks to our Navy and Mercantile Marine, trade was maintained even during the worst period of the submarine offensive.

Calcutta.—Between 1913–14 and 1918–19, the ordinary revenue of Calcutta Port dropped from 151¼ lakhs in 1913–14 to 118½ lakhs in 1917–18, after which trade revived and the revenue increased to 138½ lakhs in 1918–19. Unfortunately, there was no reduction in expenditure, which was 156½ lakhs in 1913–14, and about the same in 1918–19. It was therefore necessary to put on a war surtax, which from 5 lakhs in 1914–15, increased to no less than 52 lakhs in 1918–19. The net registered tonnage of vessels visiting the port dropped from 4¼ million to 2¼ million, coal exports from 3 million tons to 1⅓ million, and imports from 1,800,000 tons to 1,050,000.

Bombay.—The ordinary revenue of Bombay increased from 95¾ lakhs in 1913–14 to 188½ lakhs in 1918–19, but the expenditure increased from 79¼ lakhs in 1913–14 to 176¾ lakhs in 1918–19, and in the latter year there was in addition a small war surtax amounting to 4 lakhs. The net registered tonnage of shipping engaged in trade, *i.e.*, exclusive of transports, dropped from 4,656,000 to 3,785,000. Turning to trade, there was a great falling off in imports, iron and steel dropping from 238,000 tons to 29,000 tons, but coal exports increased from 106,000 tons in 1913–14 to 973,000 in 1916–17, and dropped to 720,000 in 1918–19. Grain exports remained level, but manganese ore dropped from 612,000 tons to 184,000 tons, and cotton bales from 2,195,000 bales to 951,000 bales.

During the war 3,245 transports and 893 hospital ships either entered or left the port, and the total number of troops and *personnel* passing through the port amounted to 2,297,924, of which over half a million were either sick or wounded.

The coal railed into the docks during the war for bunkering hired transports and hospital ships came to 2,453,210 tons, and the quantity of stores shipped in transports, or landed from them, between November, 1916, and December 31st, 1919, was 2,280,353 tons.

Karachi.—The revenue and expenditure remained fairly steady. The ordinary revenue in 1913–14, was 47 lakhs; in 1915–16, 33½ lakhs; and in 1918–19, 53 lakhs; ordinary expenditure, 38⅓, 36¾, and 52½ lakhs respectively. Karachi has only one export trade, viz., wheat, and that fluctuated from 907,000 tons in 1913–14 to 550,000 tons in 1915–16, rising to 1,051,000 in 1917–18, and dropping to 399,000 tons in the famine year of 1918–19.

Rangoon.—In 1913–14 the revenue was 51¾ lakhs; in 1918–19, 48¾ lakhs; and the expenditure, which was 37 lakhs in 1913–14, increased to 42½ lakhs in 1918–19. A small surtax was put on in 1917–18, which brought in 3 lakhs, but it has now been taken off. The tonnage of shipping, which was 2,937,000 in 1913–14 was 2,300,000 in 1918–19. Imports dropped from 1,230,000 tons in 1913–14 to 713,000, but exports increased from 3,300,000 to 3,374,000 tons in 1918–19.

Taking all things into consideration, the ports of India, except Calcutta, have come well out of the war, and their rates and dues have been very little increased, whilst the interference with trade has been of a purely ephemeral nature.

Port Administration.

The administration of the major Indian ports has followed that adopted in other parts of the

British Empire. In the first instance, the ports were either managed by municipalities, who were apt to regard the port as a useful contributor to the town revenues, and to divert the port funds to municipal purposes, or they were controlled by Government through an officer known as the Master Attendant. Finally, as the ports grew in importance, they were created corporate bodies, with functions and powers granted by the legislature, and were to a certain extent permitted to work out their own salvation, so long as they did not make too frequent demands on the public purse.

The principal features of these Indian Port Trusts are as follows, although differing slightly at various ports.

The Board, except at Calcutta, usually consists of a whole time chairman, who is the chief executive officer and general manager, and is appointed by the local Government, a certain number of trustees, either holding their appointments *ex officio* or nominated by Government, and a number of elected trustees, the latter being generally chosen by the European and Indian Chambers of Commerce and Trade Associations.

The Board has definite powers and can levy rates and dues on vessels and goods according to schedules which have to receive the sanction of the local Government and be published in the local *Gazette*.

The Board can borrow money with the previous sanction of the local Government, or the Governor-General in Council, according to the amount to be borrowed.

The Board is under an obligation to prepare an annual estimate of revenue and expenditure and to submit the same to the local Government for sanction, and the Board can prepare and sanction a schedule of staff.

In the matter of works, a list of those to be undertaken is given in the Act, and no work exceeding in value sums varying from fifty thousand to two lakhs of rupees can be executed, unless plans and estimates have been approved either by the local Government or in certain cases by the Governor-General in Council.

Finally, Government reserves to itself the right of control in various ways, and the accounts are audited by the Government Audit Department.

In addition to their own Acts, the Port Trusts are affected by the Indian Ports Act, under which port dues are levied, the Sea Customs Act, and various other Acts and Orders.

The Port Trusts usually have their own home agents, through whom machinery and stores are purchased, and their own consulting engineers, who give an opinion when asked to do so.

Generally speaking, the Port Trust Acts are well thought out, and, on paper, appear to be effective, whilst the control by Government is most complete.

The minor ports are administered by the local Governments direct through the Marine Department. In Madras an officer known as the Presidency Port Officer, who is usually a senior officer of the Royal Indian Marine, manages the ports with the assistance of local port officers and local advisory bodies, and in Burma there is a Royal Indian Marine officer at each minor port, who is under the orders of an officer in Rangoon called the Principal Port Officer, Burma.

Railway Ports.—There has recently been an innovation in the general policy of port administration, and two railways have been entrusted with the control and management of ports, the Bengal-Nagpur Railway at Vizagapatam, which is under construction, and the Assam-Bengal Railway at Chittagong.

Defects of Present System of Port Administration.

The defects of administration under Port Trusts are similar to those that obtain elsewhere, viz., that local bodies are apt to look at port affairs chiefly from their own standpoint instead of from the larger and Imperial point of view, and that they are as a rule devoid of imagination and courage and prone to opportunism.

A Port Trust in India labours under immense difficulties compared with similar institutions in Great Britain. Amongst others, they suffer from (*a*) lack of competent supervision and often of competent counsel; (*b*) the constant change of *personnel* whereby it is rare for any one individual or set of individuals to see the fructification of their policy. Moreover, the majority of the members of an Indian Port Trust are very ignorant of port work, and the Europeans, who are often on the verge of retirement, take, as a rule, but little interest in schemes which will only come into being after they have left the country. The members and staff have also not the opportunities of acquiring experience such as is obtained in the United Kingdom, where officials and trustees of ports have ordinarily only to take a short railway journey to compare notes with any one of fifty neigh-

bouring ports. As in all administrative work in India (and not only in India), the personal equation is generally the most important factor in efficiency, and affairs are left largely in the hands of a whole-time chairman, who, unfortunately, is at times selected without any previous experience of port work, and at the time of his appointment only knows a port as a place he passes through on his way from and to England. This is, in my judgment, a grave mistake. The management of a railway is not as a rule entrusted to a man whose sole experience has been that of a passenger, but to an officer who has worked his way through the various grades; and I see no reason why the management of a port should not be dealt with on similar lines. A chairman who is not an expert is more or less in the hands of his Board, and when, as frequently occurs, there is divergence of interest among the mercantile representatives, he is apt to take the line of least resistance and vote with those who are most insistent.

I do not wish to assert that a member of the Indian Civil Service, Public Works Department, or the mercantile community, if no one with practical experience of port work is obtainable, cannot make an efficient head of a Port Trust, provided he is given an opportunity of obtaining the necessary experience; but, in my opinion, a person with no previous experience should, before being appointed, work for at least a year in the offices of the port as a student and thereafter be given a year to study port affairs at the great ports of the world, in order to fit him to bring sound judgment to bear on the many and diverse problems he will have to deal with, and to recognise the national as well as the local interests frequently involved in questions that come before him.

The same lack of knowledge and experience in port administration is met with when references are made to higher authority. Questions of policy and schemes of improvement that are beyond the powers of the Port Trust are referred to the local Government or to the Government of India, as the case may be. But, as it is rare to find anyone at the headquarters of Government with a practical knowledge of ports, these questions are seldom decided strictly on their merits, and as it is always safe to question expenditure, an easy way of disposing of a case is on financial grounds. When I went to Rangoon in 1901, as Chairman and Chief Engineer of the Port Trust, I found the province being slowly strangled for lack of port accommodation and development. Not only were port facilities deficient, but there was no port staff, and I found myself saddled with the duties of Chairman, Chief Engineer, Secretary, Chief Accountant and Traffic Manager.

By a certain amount of strenuous work I had got affairs into some shape and order and had elaborated a scheme for port improvements. I then asked for some assistance in the shape of a secretary and a couple of assistant engineers, my proposals being cordially supported by my colleagues on the Board. In those days the Rangoon Port Commissioners had to ask the sanction of Government to any expenditure, a case in point being the increase in the pay of the cook on the pilot vessel by a shilling a month, and such a serious increase in the staff as the appointment of a secretary and two engineers was viewed with alarm and suspicion by the local Government, who informed the Port Commissioners that their proposals were *primâ facie* extravagant and unsupported by adequate reasons, and told me I was an expensive luxury. At a later date an important work of improvement at the Port of Rangoon was delayed for three years, because the Government of India had no engineer experienced in work on tidal rivers, whilst only recently when I held a war appointment in Simla, port questions were frequently referred to me, because, as one high official remarked, "there was no one in Simla who knew anything about ports."

Naturally under these circumstances no use is made by Government of the power given to it in the Port Acts to insist on the execution of necessary works.

Minor Ports.—The defects in the administration of minor ports are similar to those in major ports, but are accentuated by constant shortness of funds, colossal ignorance, and a general lack of interest in their development.

Railway Ports.—The administration of railway ports has not yet come into actual operation, and although there is a good deal to be said in their favour under special circumstances and conditions, I view with a certain amount of misgiving the decision of Government to establish railway ports in India; it is, moreover, a complete departure from the previous policy of the Government of India.

By a railway company, a port is merely regarded as a feeder to their particular railway system, and not for the general welfare of the community, and port traffic which is destined for the railway is encouraged at the expense of traffic which does not require railway

facilities; whilst, by charging specially low port dues and charging the deficit to the railway revenues, a railway port can compete unfairly with Port Trusts, who are limited by their Acts to the provision of port accommodation.

Calcutta has very good reason to complain of the action of Government in giving Vizagapatam and Chittagong to railway companies, because not only can they compete in an ordinary and perfectly fair way by the capture of trade—and there is no doubt a great percentage of Calcutta's trade will go to Vizagapatam if the railway company succeeds in making a port there—but because of the special facilities granted in the matter of raising capital for the construction of the port.

Calcutta, as a Port Trust, has to go to the public for a loan, which involves the upkeep of a sinking fund; but a railway company can be provided with funds either from advances by the Secretary of State, or by issue of debentures or debenture stock by the railway company, or by the issue of further ordinary shares; and the formation of a sinking fund for repayment of capital expenditure is not usually contemplated.

The railway also possesses a monopoly of terminal facilities for its own railway, and competition by other railway lines or by inland water transport is usually regarded with disfavour, regardless of the fact that the port with the best prospects and the one that is of the greatest use is that which has the widest choice of transporting facilities to the interior.

(*To be continued.*)

THE PRINCIPAL INDUSTRIES OF THE SERB-CROAT-SLOVENE STATE.

The following particulars regarding the principal industries of the State of the Serbs, Croats and Slovenes are extracted from a document prepared by the State Minister of Commerce, and translated by the American Embassy at Belgrade:—

While it is difficult to describe the industrial conditions in the new Provinces, it may be said generally that the country has considerable stocks of raw materials, and conditions are favourable for developing various industries. There are in the Western part large quantities of coal and wood, a considerable amount of water-power, and many trained workmen; but the industries encounter great difficulties as they are dependent upon foreign capital.

The metal industry was first developed in the western part of the country, but has not yet reached the point of turning out heavy metal pieces. This is due to the lack of modern equipment. According to the statistics of 1910, the manufacturing of metals was confined to nine works. The largest were the Government works at Kraguyevatz. Two smaller ones at Belgrade had a capital of 6,276,971 dinars, and an annual business of 12,000,000 dinars. There is at Wares, in Bosnia, a foundry able to manufacture 100,000 tons of iron, three-fourths of which was previously exported to Austria and Hungary. In Slavonia there is not much iron, and owing to this, only one foundry has been erected at Skednj, near Trieste, where in addition to Slavonia iron, Spanish, Algerian and Italian iron has been used. This establishment has manufactured about 10,000 tons per annum. There is an important iron industry in Jasenica and Yavornik, in Slavonia, which produces 30,000,000 crowns worth of various iron products. In Croatia there is also, to some extent, a developed iron industry. Various implements of iron and steel are produced in other enterprises in Slavonia. There are no foundries in Serbia. Investigation shows, however, that there are rich iron deposits, and it is expected that there will be a great development of the mining industry there.

In Bosnia and Herzegovina there are produced about 2,800,000 tons of brown coal and 130,000 tons of first quality coal. There are many deposits which are still untouched. Manganese mines with a yearly production of 20,000 tons, and some antimony and pyrites mines are also found here. Slavonia possesses lead mines with a yearly production of 18,000 tons, and zinc mines with a yearly production of 30,000 tons. In Idria (Slavonia) are the well-known quicksilver mines which produce 130,600 tons of ore yearly, from which are extracted 820 tons of quicksilver valued at 3,878,000 crowns.

The textile branch of industry has been so well developed that in 1910 the needs of the Army were covered by home productions. The thread was imported chiefly from England, and the raw material was partly obtained in the country and partly from Banat and Hungary. There were three wool-spinning mills with 6,120 spools and 180 spindles, which produced material valued at 2,500,000 dinars. The home clothing material industry in the district of Pirot was valued at 400,000 dinars in 1910. There are also two hemp-spinning works and a knitting factory in the country. Hemp factories are found in Batchka, Banat, Baranya, and Srem. In Trzich and Litija are some factories capable of producing 3,000 tons of cotton thread and 3,750 tons of cotton goods, but owing to the lack of cotton they are not now working.

The home carpet industry in the Pirot district is also worthy of note. Carpet factories are found at Sarajevo, Bosnia, and at Becskerik (Banat).

In Slavonia (Trzitch, Schoschtanj and Maribor) about 600,000 hides are worked. The boot and shoe factories produce about 1,000,000 pairs of boots and shoes. There is one factory at Temesvar, Banat, with a capacity of 800,000 pairs. There are similar enterprises in Croatia at Zagreb, Karlovatz and Osek. Serbia has two factories for manufacturing leather and hides, the value of the

manufactured hides of lower quality in 1908 being 1,117,462 dinars. The better quality of leather was imported.

There are in the country about fifty large mills with a production of 100,000 cars of flour. The up-to-date mills are especially in the Banat, Batchka, Baragna and Slavonia. In 1909 there were in Serbia 229 mills of the following capacities: 1 mill producing in 24 hours, 10 cars; 16 mills, 2 to 5 cars; 22 mills, 1 to 2 cars; 86 mills, ½ to 1 car; and 104 mills, 500 to 5,000 kilos. In 1909, 1,012 cars of flour and 861 cars of bran were exported. The total production in that year was estimated at 9,616 cars of flour and 3,540 cars of bran.

In the new Provinces there are six large and up-to-date sugar factories, the production of which will be quite sufficient for the country's needs. This industry has been fairly developed in Serbia. There is one factory at Belgrade which produced in 1909, 909 cars, and one in Tchuprija which produced in 1911, 840 cars.

There are important chemical works in Slavonia and Croatia. In Slavonia these are at Hrsnik, Celj, Ruhce and Liubliana. Sulphuric acid, glauber salts, and crystal and bicarbonate of soda are produced. At Kamnik there is a powder factory. Some very important tannin factories are found at Zupango and Mitrovitch, Croatia. In Bosnia (Yayce and Bosna Brod) are carbide works and refineries of petroleum and mineral oils with a capital stock of over 9,000,000 crowns. A considerable quantity of pure alcohol was produced in Batchka, Baranja and Banat, but this activity ceased owing to shortage of coal. The chemical industry has just been introduced into Serbia. In addition to the State powder works there were at Belgrade a few acid works, a soda works, two soap factories, a dye factory, and a match factory.

In the new Provinces there are many fine forests, and owing to the water-power available this industry has been greatly developed. There are about 2,300 sawmills, with 4,000 saws. The value of the products of the industry is about 100,000,000 crowns. The timber industry is developed on a large scale in Bosnia. In 1913, 2,500,000 cubic metres of wood were exported to Holland, Italy, Egypt and Germany. In Croatia there is also an important timber industry, and in Serbia there are about fifty sawmills, but only five of importance. The timber industry at present represents a very large part of the commercial budget of the country.

Other industries of the Serb-Croat-Slovene State which may be mentioned are brewing, electrical, paper, cement, glass, brick and tobacco. With the exception of a few mines, the larger part of the factories of the country were destroyed during the war by the enemy. It is hoped, however, that these industries will soon be reconstituted.

GRAPHITE DEPOSITS IN SIBERIA.

Extensive deposits of graphite exist in north-western Siberia on the left bank of the River Kureika, near its junction with the River Yenisei, ninety miles from the mouth of the latter river. The graphite area forms a horizontal plateau, the elevation of which varies from 20 to 50 ft. above the normal level of the River Kureika. The plateau contains two layers of graphite, which is of a solid, steel-grey colour, soft, and of an excellent quality for the manufacture of pencils.

The graphite mines of Siberia were discovered in 1859 by the celebrated explorer Sidoroff, who sent samples of the metal to Russian and foreign laboratories for analyses. These analyses gave the following chemical composition: 89·51 per cent. carbon, 0·60 per cent. hydrogen, and 9·89 per cent. residue. These analyses were confirmed in 1907. The carbon constituent is said to be superior in quality to that found in graphites in other parts of the world. The graphite is not inflammable and is very plastic.

At present, writes the United States Consul at Omsk, it is practicable to ship the graphite only during the summer months by sea from the Yenisei River through the Arctic Ocean. It is believed that in the future the graphites from these mines will supply Russian demands, and that large quantities will be available for export.

The chief sources of graphite have hitherto been Ceylon, Bohemia, Germany, France, and the United States. The annual world production has been, approximately, 120,000 short tons (of 2,000 lb.).

NOTES ON BOOKS.

Social Life in England through the Centuries. By H. R. Wilton Hall. London: Blackie & Son, Ltd.

Since the discovery was made that the history of a country is something more than a string of dates of battles, and of the accessions and deaths of kings and queens, a good deal has been done in the schools to make the story of the past appear to the scholars as something that once had life and still has interest, as showing how the present has developed out of what has gone before. Mr. Wilton Hall has written a book which, we think, should be useful in this respect, for he throws a great deal of light on the social life of this country from the days when its inhabitants lived in caves and pits. He gives us glimpses of the manner in which our ancestors lived at various stages of our history; he traces the development of Anglo-Saxon tuns and vills to wooden towns and villages, the evolution of houses, schools, universities, sports, roads, railways, etc. The book is illustrated with many excellent figures, and altogether it should prove a popular addition to the school library.

Water Powers of British Columbia. By Arthur V. White, Consulting Engineer, Commission of Conservation, Canada, assisted by J. Vick. Ottawa, 1919.

This report, which runs to nearly 650 pages, is a compendium of data relating to the water-power

resources of British Columbia. It opens with a statement of the principles which should be observed in the conservation and utilisation of inland waters, and discusses certain important features which should characterise reliable water-power data. This is succeeded by a comprehensive historical survey of water-power legislation in the Province, together with discussions of subjects cognate therewith. Tabular lists are given of the estimated possibilities of water-power sites, and these are largely based on results obtained from special field investigations conducted by the Commission of Conservation. Digests of stream-flow, meteorological and other hydrometric records follow, and the volume concludes with a full bibliography and index.

In a country like British Columbia, much of which is covered with lofty mountains and with dense forests, it is impossible to obtain anything like reliable estimates of the water-power. This is fully recognised in the report, which is careful to give only general and conservative estimates. The total, in round figures, is given at about 3,000,000 horse-power, of which the Columbia River and tributaries contribute 610,000; the Fraser River and tributaries, 740,000; Vancouver Island, 270,000; the mainland Pacific Coast and islands, 630,000; and the Mackenzie River and tributaries, 250,000. There is still a great deal of territory which it has not yet been possible to investigate fully, and these areas may be found capable of adding very considerably to the estimated powers.

The report is illustrated with a large number of photographs, which give an excellent idea of the beauty of the country, and also of the difficulties of the field investigators in making their way through some of the trackless regions.

The Mineralogy of the Rarer Metals. By Edward Cohen, A.R.C.S., F.I.C., and William Ord Wootton, A.R.C.S., B.Sc. Second edition. London: Charles Griffin & Co., Ltd. 10*s.* 6*d.*

The first edition of this book appeared in 1912. It was designed to meet the needs of prospectors and practical metallurgists, and it contained in a compendious and handy form a great deal of information which had hitherto been only obtainable in Dana's monumental work or in scattered monographs. It achieved so much success that a second edition has now been called for.

Since the publication of the first edition a great deal has happened to bring the rarer metals into greater prominence than ever before. Platinum, for instance, became very scarce and valuable during the war, with the result that research was stimulated in the hope of finding substitutes for it, and several alloys have been placed on the market which promise to prove of permanent value. Zirconium is another metal which has received a great deal of attention in recent years. The carbide is employed as a filament for incandescent lamps, and also as an abrasive. The oxide is used as a refractory body in the manufacture of zirkite bricks and small utensils for laboratory purposes, such as crucibles, muffles, combustion tubes, and resistance cones. Combined with yttrium earth oxides it is used in Nernst lamps, and as a substitute for calcium oxide in limelight cylinders. Its uses are being extended in other directions also, *e.g.*, for rendering opaque the enamel on hardware, and as a substitute for bismuth subnitrate in the making of X-ray photographs.

The book is arranged very conveniently, notes being given on the properties of each metal, its preparation, commercial applications, and detection. The sections on commercial applications and the chapter on "Geographical Distribution" have had to be rewritten and largely expanded.

The War Garden Victorious. By Charles Lathrop Pack. Philadelphia: J. B. Lippincott Company.

When the war broke out in 1914, between twenty and thirty million men were suddenly called away from their usual pursuits. The majority of these were engaged in agricultural pursuits, and thus at one blow practically all the farms of the belligerent nations were swept clear of male workers. The natural result of this was very soon seen in a world shortage of foodstuffs, which was greatly intensified by the general failure of crops in 1916. The burden of feeding the Entente countries fell to a large extent upon the United States, and it soon became necessary to take steps to make very large increases in the production of that country. At the instance of the author of this book a National War Garden Commission was formed, of which he became President, and with characteristic energy it set to work to educate the hundred million population of America in the needs of the hour. How this task was undertaken, and with what results, is told very effectively in the present volume. The American people (men, women, and children) rose nobly to the occasion. Over five million war gardens sprang into existence, and the value of their produce in 1918 was estimated at half-a-billion dollars.

The book is illustrated with a number of photographs showing gardens, some of which look very fruitful and attractive, canning teams—a great deal of excellent work was done in connection with drying and preserving food of all kinds; while not the least interesting part is the concluding section which contains a collection of the leaflets published and distributed by the National War Garden Commission.

GENERAL NOTES.

The Electrification of Seeds.—Mr. Martin H. F. Sutton has published an interesting bulletin giving the results of a number of germination and field tests conducted last year on carrot, swede, cabbage and mangold seeds. Experiments were made with untreated seeds, with seeds electrified by the Wolfryn process, in which the seeds are immersed in a solution of common salt and water

or of calcium chloride of water, through which an electric current is passed. After immersion the seeds were dried at a temperature of 100° F. and then sown. On the whole the tests do not appear to show any advantage from the treatment, with perhaps the exception of mangold, where the germination of the electrified seed was 94 per cent., as compared with 82 per cent. for the untreated seed; while in the field tests the electrified mangold seeds yielded 62 lb. per pole more than the untreated seed. In other cases either the electrified seed gave a lower yield than the seeds treated in other ways, or the increase was so small as to be negligible.

New Source of Alcohol.—Much attention has been given in recent years to the question of manufacturing alcohol within the Empire for use as motor spirit. In the current number of the *Bulletin* of the Imperial Institute the possibility of utilising the mowra flowers of India for the purpose is discussed. These flowers possess thick, juicy petals, rich in sugar. They are used by the natives as a foodstuff, and especially for the preparation by fermentation of an alcoholic liquor called daru or mohwa spirit. A single tree will yield as much as 200 to 300 lb. of flowers in a year. The tree also produces a valuable oil-seed, which is exported in fairly large quantities to Europe. During the war the flowers were used in India for the production of acetone, the yield being said to be ten times as much as that obtained by distilling wood, which is the usual source of this substance. The demand for acetone in India in peace times, however, is not great, and large quantities of the flowers would be available for the manufacture of alcohol, and would appear to be an exceptionally cheap source of this material, as the yield is high compared with that from potatoes and other materials commonly used, about ninety gallons of 95 per cent. alcohol being obtainable from one ton of dried flowers. It has been estimated that in the Hyderabad State alone there are already sufficient mowra trees for the production of 700,000 gallons of proof spirit per annum, in addition to that necessary for the local liquor requirements. It is suggested that the most profitable way of utilising the flowers would probably be as a source of mixed motor spirit of the "natalite" type for use in India. That motor spirit can be produced on a manufacturing scale in India from mowra flowers has already been demonstrated, and it is stated that running trials with the spirit proved satisfactory.

MEETINGS OF THE SOCIETY.

Indian Section.

Monday afternoon, at 4.30 p.m.:—

May 31.—Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Friday afternoon, at 4.30 p.m.:—

June 18.—Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.) The Right Hon. Lord Meston, K.C.S.I., LL.D., will preside.

Indian and Colonial Sections.

(Joint Meeting.)

Friday afternoon, at 4.30 p.m.:—

June 4.—Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire." The Right Hon. E. G. Pretyman, M.P., will preside.

Cantor Lecture.

Monday evening, June 7th, at 8 p.m. (lecture postponed from April 26th):—

Walter Rosenhain, B.A., D Sc., F.R.S., Superintendent, Department of Metallurgy, National Physical Laboratory, "Aluminium and its Alloys." (Lecture III.)

Syllabus.

Special Uses of aluminium alloys—Castings for automobile and aeroplane parts—Castings for aero-engines—Pistons and piston alloys—Properties at high temperatures—Automobile and aero-cylinders—Other engine parts—Structural uses—Rigid airships, aeroplane spars, and wing-coverings—Possible future developments.

MEETINGS FOR THE ENSUING WEEK.

Tuesday, May 25...Royal Institution, Albemarle-street, W., 3 p.m. Major C. E. Inglis, "The Evolution of Large Bridge Construction." (Lecture I.)

Wednesday, May 26...Aeronautical Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Sir Richard Glazebrook, "Some Points of Importance in the Work of the Advisory Committee for Aeronautics."

Thursday, May 27...University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. E. H. C. Walsh, "Tibet."

Royal Society, Burlington House, W., 4.30 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Major H. Best, "The Mystery Port, Richborough."

Friday, May 28...Royal Institution, Albemarle-street, W., 9 p.m. Professor W. L. Bragg "Crystal Structure."

Physical Society, Imperial College of Science, South Kensington, S W., 5 p.m.

Saturday, May 29...Royal Institution, Albemarle-street, W., 3 p.m. Dr. J. H. Jeans, "Recent Revolutions in Physical Science. (1) The Theory of Relativity."

Journal of the Royal Society of Arts.

No. 3,523. VOL. LXVIII.

FRIDAY, MAY 28, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Monday, May 31st, at 4.30 p.m. (Indian Section.) Albert Howard, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India, "The Improvement of Crop Production in India." Sir Robert W. Carlyle, K.C.S.I., C.I.E., will preside.

Friday, June 4th, at 4.30 p.m. (Joint Meeting of Indian and Colonial Sections.) Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E., "The Oil Resources of the British Empire." The Right Hon. E. G. Pretyman, M.P., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

POSTPONED CANTOR LECTURE.

The third lecture of the course on "Aluminium and its Alloys," by Dr. Walter Rosenhain, F.R.S., Superintendent of the Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, which was postponed from April 26th, in consequence of the sudden illness of the lecturer, will be delivered on Monday, June 7th, at 8 p.m.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

THE PORTS OF INDIA: THEIR ADMINISTRATION AND DEVELOPMENT.

By Sir George Buchanan, K.C.I.E.

(*Continued from page* 441.)

Proposed Improvements in Port Administration.

I have pointed out some defects in the existing system of port administration, and will now put forward some suggestions for reform.

On the whole I am in favour of a continuation of control by bodies of men representing the various interests, not because it is the most efficient method of working a port, a municipality, or any other public undertaking, but because it has been our policy for many years to encourage local self-government. That it is not essential to create a Port Trust with a large number of members is shown by the fact that one of the best-managed ports in the world is Montreal, with a Harbour Commission of three —a President and two members—and one of the worst-managed ports is Calcutta, with a Commission sixteen in number.

Assuming, however, that the ports continue to be managed by bodies of trustees, I am of opinion that their powers and responsibilities should be materially increased, and that the chairman should be a well-paid, practical and thoroughly competent man invested with considerable authority and wide powers, especially in matters of detail. I have also for a number of years held the opinion that there should be a system of unified direction and control of ports by the Imperial Government of India, who should take a much livelier interest in the higher policy of port development, and the co-ordination of ports with interior transport.

At the present time the Government of India is supposed to exercise a control over ports in various ways, viz., new legislation, approval of loans, sanction to execution of works, etc.; but although the Government of India has Railway, Irrigation, Medical, Agricultural, Public Works, and other departments with experts attached to each, it has no officer or officers at headquarters with special knowledge or interest in ports, the result being that port matters are bandied about from one department to another and finally, I believe, find a resting-place in the Education Department.

Port development is, however, just as important as railway or road development, the port

forming one of the three links of transportation, viz., ship, port, and railway, or road, or river, whilst transportation is a cost of production equally with materials and labour.

The Chairman of the Dominions Royal Commission, in an address to the London Chamber of Commerce on the subject of the improvement of sea communications, advocated a bold and progressive policy of harbour construction for the accommodation of large ships. In his address, Lord D'Abernon pointed out that the pre-war facilities for commercial intercourse by sea were far below the best available standard, that there was little scientific anticipation of coming events, and still less was there preparation on a generous scale for future possibilities, whilst it seemed, indeed, as if other nations had applied to the problem of harbour development a clearer vision of the future and a broader comprehension of progressive tendencies.

He proceeded to point out that this condition of affairs could hardly be altered scientifically so long as harbour development was left to isolated and independent action by individual harbour authorities, and that the responsibility for development of harbours along great ocean routes must be dealt with by superior State authority, acting independently of the immediate interest of individuals.

To those who have studied the subject, there is nothing new in Lord D'Abernon's statement, and more or less the same opinion was expressed some years ago by the Royal Commission on the Port of London, who, in their report, commented on the difficulty of creating a port without State aid, and when discussing the great development made by the Continental ports in the last few years, principally owing to lavish expenditure on the part of the State, remarked :—

"The power of undertaking large expenditure and of working for a long time at a loss, with a view to compensation in a distant future, is no doubt in the keen world competition an advantage possessed by undertakings which have the force of Empire, State, or a great city behind them. If in some countries national and municipal resources are thus employed, it becomes most difficult for private enterprise elsewhere to hold its own against the intelligent, far-sighted, and formidable rivalry thus created."

It is an unfortunate fact that in India there has been no really comprehensive or scientific inquiry into India's port requirements, and the ports have struggled on with little encouragement, little financial assistance, and no advice. I do not remember that during the whole time I was in Rangoon one useful suggestion for the betterment of the port ever came to the Port Commissioners from either the Local Government or the Imperial Government—not that they did not care, but because port work was unfamiliar to them.

The best solution of the whole problem would, in my opinion, be the creation of a Department of Communications to deal with railways, inland waterways, and ports, roads being left to the local Governments. In regard to ports, the control should be in the shape of guiding the policy in the interest of the Empire, rather than interference with detail, but there should be, at the same time, an insistence on the execution of vitally important works, such as, for instance, the improvement of the Hooghly River, and the provision at Karachi of adequate facilities for the grain trade. The Port Trusts should also be helped financially, by Government including in its loans the sums required for port development, the money being transferred to the port authority at a slightly enhanced rate over and above the Government loan terms. At present the Government contents itself by scrutinising the application of a port authority to float a loan, before sanctioning its issue, and by seeing that the loan is not put upon the market until all Government loans have been floated and disposed of.

In this connection I also suggest that there should be a more comprehensive inquiry by competent authority than at present exists into the cost and necessity for works often involving a great expenditure. In the United Kingdom new projects for ports, waterways, or docks are considered by Committees of the two Houses of Parliament, and the very best expert evidence is obtained and laid before them, whilst, in the case of an opposed Bill, frequently weeks are taken up in hearing counsel on both sides and examining witnesses. There is a full ventilation of objections, and the final decision of the Committee is accepted as disinterested and sincere. One could not imagine in this country, for example, a railway company being permitted to build a port and given preferential treatment over a neighbouring Port Trust without the fiercest opposition on the part of the Port Trust, and action on the part of the port bondholders. I often wonder that the debenture and bondholders of the Indian ports do not take more interest in their administration, because, so far as I am aware, the Government of India does not guarantee the various loans, and there is no reason why, under the influence of bad management and misfortune, a

port should not find itself unable to meet its liabilities, as happened recently in the case of a home port.

A new department, such as I have described, composed of men of real knowledge and experience, would be of enormous value in developing India. I should, however, deprecate the new department bearing any resemblance to the present Railway Board, and I think it would be necessary to recruit some of the members and the staff from outside India, and to pay them on a commercial rather than a Government basis.

Port Development.

The immense amount of work that must be done in the future in India in port development is not generally realised, and as first and foremost there must be a sufficient depth of water in the river and harbour entrances, it will be well to consider what will possibly be required in the years to come.

East of Suez, port development has been largely guided by the size of vessels which can pass through the Suez Canal, and although the war awakened the Indian ports to the fact that there is an alternative route round the Cape, and a number of vessels visited India which could not have passed through the Canal, the depth in the Canal is the key to the situation. Before 1884, the maximum draught of vessels permitted was 24 ft. 6 in.; in 1901, 25 ft. 7 in.; in 1907, 27 ft., and at the present time, 30 ft., whilst the scheme of improvements now being carried out aims at permitting the transit of mercantile vessels of 33 ft. draught. Supposing we add 2 ft. to the proposed draught of 33 ft., and make 35 ft. the maximum to work to in the near future, then, according to a recent ruling, there should be 40 ft. of water in entrance channels through sea bars, 37 ft. in ordinary entrance channels, and 36 ft. in wet docks and alongside quays and wharves. That is to say, there is not a single port in India which could take a vessel of such a size. Not only do we require existing ports improved and extended and their spheres of influence and transport facilities behind the port critically examined, but the development of new ports, wherever demanded by trade, such ports competing fairly with others in the neighbourhood, and being controlled by local committees.

There are several ports in Southern India worthy of development, and for the last thirty years report after report by engineers has been received, considered, and put aside. In my judgment this is not the way to approach the subject, as what is required in the first instance is a careful examination and report on the prospective trade of the port, the area of country to be tapped, the possibilities of increasing that area, and giving better transport facilities to the port, also the prospective revenue and maximum capital expenditure permissible to begin with. Armed with this information, the engineer can and must cut his coat according to his cloth and say what can be done for the money. A grandiose scheme prepared without this information is a mere waste of time. One has also to consider the vested interests that exist at nearly every port in the shape of rights and privileges held by individuals or trading companies, as by the disregard or neglect either to compound or make use of these, the development of many a port has been postponed for years. It is therefore generally better to assimilate these interests and to make use of them for the public good rather than to keep them in opposition.

It must also be remembered that the success of a port depends on its management as much as its engineering, and that the two branches must work hand in hand, constantly devising schemes for the giving of better facilities for trade, as a port can never be said to be completed, and there are very few ports which could not have their expenditure reduced and their revenues increased by improved methods of administration.

The new port of Basra is not an Indian port, but it is being developed on the lines of Indian ports, and I am therefore tempted to use it as an illustration and warning, because I am afraid nearly all the defects I have pointed out in this paper on port development and administration can be seen there, either active or in embryo. In the arrangements for the conversion of the port from war to civil requirements, there has been no competent counsel, and there has been no properly thought-out scheme for the administration of a civil port, by people versed in port affairs. A Port Trust is to be established, but, as I have already pointed out and illustrated by examples, the creation of a Port Trust does not make a port.

Schedules of rates and rules and regulations have been copied from other ports, regardless of the fact that a new port in a new country requires individual treatment, and the rates have been fixed on a scale which will make Basra one of the expensive ports of the East. This is a matter for regret, because the immediate future of Mesopotamia and Persia lies as much

in correct port administration and development as in anything else.

I am afraid this paper has reached an inordinate length, and I do not expect that the views I have expressed will meet with universal approval. The paper will, however, have served its purpose if it provokes discussion, and induces my audience and the public at large to realise that there is a great deal of work to be done in developing Indian ports, and that it is useless to create a vast industrial India if there is not at the same time a wise and far-seeing scheme for improving and developing ports and transportation facilities in general.

DISCUSSION.

THE CHAIRMAN (The Right Hon. Edwin S. Montagu, M.P.) said he did not propose to discuss the paper, because he was present to listen and to take note rather than to talk on so very technical a subject. The author had confessed that his paper was highly controversial, and they could only hope that among those who would take part in the discussion there would be some full-blooded and lusty members of the Calcutta Port Trust; then there would be some fun. There could be no doubt, however, as to the importance of the subject. India's first need was to increase the standard of living and the wealth of her people, and that could only be done by the development of her glorious resources, which depended upon the development of her railways and ports. He could only say on one political subject that the suggestion that there should be a Central Department dealing with ports, railways, roads so far as they were not provincial, docks, posts and telegraphs, and civil aviation, had already been put forward in connection with the reform scheme and the reallotment of the functions of the Governments in India. That was now under consideration, and, particularly after what the author had said that afternoon, it seemed to him that a strong *primâ facie* case for such an organisation had been made out, and he hoped its consideration would not take long.

SIR CHARLES C. MCLEOD began his remarks by congratulating the Society on having induced the Secretary of State for India to be present at the meeting. With his many duties it must be difficult for him to go through all the literature that was sent to him, and it was quite possible that if he had not been present at the meeting the very important subject under discussion might have escaped his notice. He (the speaker) intended to confine his remarks entirely to the port of Calcutta. The author's assertions with reference to that port were of a very sweeping character, but he did not think they were too strong. At the annual meetings of the Bengal Chamber of Commerce in 1913 and 1914 he referred to the question at considerable length, and the statements he then made generally supported the attitude that had been taken up by the author. He desired to confirm the statement made in the paper that any delay at Bombay involved more than a corresponding delay in the delivery of the mail in this country. A three hours' delay at Bombay of the steamer on which he recently travelled had the effect that the delivery of the mails in London was forty-eight hours' late. While the facilities of the port of Calcutta had been considerably increased it must be borne in mind that at the present moment every warehouse in Calcutta was full up, because there were no steamers to carry away the products. The war was partly responsible for the condition of affairs that existed, but the fact remained that Calcutta at the present time could not handle her traffic. The author had struck a very sound note in advocating that the conduct of a port should be under the control of a smaller number of people than was the case at present, and he brought that into very strong relief when he compared the excellent condition of affairs at Montreal, with only three people to look after the port, with the congested state of Calcutta, with sixteen people in charge. One of the strongest points that must be borne in mind in connection with the ports of India was the fact that the trade eastward went mostly through the Suez Canal, which had been widened and deepened out of all recognition, so that it was now possible for ships of 18,000 tons to go through it. At the present time there was only one port in India, namely, Bombay, which could, at any state of the tide, accommodate a ship of that size. It was certainly necessary that in a few years' time all the principal ports of India should be able to accommodate steamers up to 15,000 tons, which they were quite incapable, in many instances, of

doing at present. Although the author was very severe in his strictures on the administration of Indian ports, he did not only destructively criticise but he put forward suggestions for better administration in the future. For instance, he made the suggestion that there should be a deep, well-buoyed and well-lighted channel extending from the sea to the entrance to docks or wharves. That was what would have to be done if the ports of India were to deal with the great increase in export trade which must come about in the near future.

Sir Charles H. Armstrong said he had been asked to speak on behalf of Bombay. His qualifications for doing so were that he was a Port Trustee for ten years, from 1904 to 1914, and it was during those years that the Alexandra Dock was planned and built. When he left Bombay in May, 1914, he sailed out of the new dock in one of the first large vessels to pass through the dock channel. He had also just returned from a visit to India, so that he possessed a certain amount of up-to-date knowledge. The suggestions the author made for improving the existing state of affairs ought to receive very careful consideration. He accepted with pleasure and without comment the author's statement that Bombay was the premier port of India. The Bombay Trust had always had a definite policy since its formation in 1873, and the author had particularly praised the engineers who had carried out the various developments of the Bombay harbour and docks. He desired to couple with those praises the Chairmen of the Ports, who in most instances had been engineers. Bombay had been very fortunate in having had a series of very able Chairmen, and he could only say that the working of the Bombay Port Trust had given the very greatest satisfaction to the commercial community. The author had suggested that the new dock should be built either alongside the Alexandra Dock or to the north of the Island near Trombay. He was inclined to agree that a new dock alongside the present docks would be inadvisable, because it would be very difficult to handle on shore the large additional traffic that would have to be moved, and it would be impossible satisfactorily to house the large number of additional labourers that would be required. The housing position in Bombay was very acute at the present time. Development work was proceeding to the north of the Island and he hoped that in a year or two, the position would be to some extent relieved. He was very glad shortly before leaving Bombay to hear of the decision which had been arrived at that no new industries should be allowed on the Island of Bombay, and that every inducement would be given to the present industries to go outside the Island. If therefore the new dock was built somewhere near Trombay it would be in close connection with the new industrial area which must arise in the near future, and it would also be very conveniently situated for railway connection with the Great Indian Peninsula and the Bombay and Baroda Railways. He was glad the author had called attention to the insufficient dredging of the Bombay harbour and its approaches. The work of dredging ought to be taken in hand at once, and, as the author stated, the mud that was raised could be used in connection with the reclamations that were now being planned. Under the heading of "Defects in Port Administration" he was surprised to find the author stated that the Europeans on the Trusts, who were often on the verge of retirement, did not as a rule take any interest in the development of the port. The author's experience might have been unfortunate, because his own experience in Bombay was directly the contrary. He expressed no opinion as to whether the Chairman of an Indian Port Trust should be a Royal Engineer, a civil servant, or an engineer of the Public Works Department. In Bombay they had had as Chairmen a succession of engineers of the Public Works Department, and they had done extremely good work. What was required in the chairman of a big port trust in India was a man of great administrative power, with big ideas and far-seeing views, and in the past they had been able to find such men for the Bombay Port Trust. The author would evidently like the chairmen of port trusts to be men sent out from home. In some cases that might be an advantage, because very experienced men could be obtained in this country, but it must be borne in mind that experienced men sent out from England would not be in their first youth. They would not know the port nor understand the trend of Indian trade, neither would they understand Indian customs, so that on many occasions they might work for a considerable time at a disadvantage. Under the heading of "Proposals for Improvement in Administration" the author suggested that a Department of Communications should be established under the Government of India, but personally he thought that unless it was a body of exceptional ability, with men of the very highest standing, it might on many occasions hamper a first-class progressive Port Trust like Bombay. He felt sure that Bombay did not wish to be controlled by any superior body unless it was a body of the very highest class of experts. The author further suggested that capital expenditure for the ports should be provided by the Government of India, which could raise the necessary money in their annual loans and lend it to the Port Trust at a higher rate of interest. That might benefit the smaller ports, but the large ports, Bombay in particular, had the confidence of the public. Bombay could raise any amount of money that it required in the open market at a very moderate rate of interest. The Bombay Trust worked under a system of sinking funds, and its whole system of finance was eminently satisfactory. He would very much regret therefore if the Bombay Port Trust had to rely upon the Government of India for its finance, because the Government of India was

limited in the amount that it could raise. Bombay at the present time was absolutely overloaded with money, which was seeking investment in works of public utility, and it was a very great pity that that money could not be utilised for the extension of the railways. He had received a letter from a prominent member of the Government of India, informing him that that question would shortly come under consideration, and he sincerely hoped it would. A great many very important capital railway works had been held up during the war owing to the want of funds, and he felt sure that they would continue to be held up for a very long time if they had to rely upon the Government to supply the necessary funds. He hoped therefore that before very long it would be possible for the railways to borrow in the open market and that their development would thereby be helped.

Sir Harvey Adamson, K.C.S.I., said he thought that all who heard the paper, whether they agreed or not with all the views which Sir George had expressed, must recognise that it was a very thoughtful paper, written by one who was a master of port administration in all its aspects. He (Sir Harvey Adamson) had been asked to say something of the Port of Rangoon—from his experience as a Lieutenant-Governor of Burma. Sir George Buchanan administered the Port with great success from 1901 to 1915. When he came to Rangoon the port was far behind the times, and very imperfectly provided with equipment for handling the large and yearly increasing traffic. The port was then administered by a body of commissioners nominated by Government, who had no real power or authority, and could scarcely commit themselves to the smallest administrative or executive act without the previous sanction of the local Government. Sir George's first task was to draft a new Act, which came into operation in 1905, and which gave the Commissioners greatly enhanced powers, though perhaps not quite so great as its author desired. With the help of this Act Sir George was able to push ahead with his schemes for remodelling the port. From 1905 onwards a large amount of money was expended on wharves, godowns, pontoons, warehouses, dredgers, and all the paraphernalia of a port, with the result that Sir George had left behind him a port which was in many respects more up to date than any other port in India. During these fifteen years the registered tonnage of shipping had doubled, the value of trade had trebled, and the revenue of the port had quadrupled. The value of Sir George's work might be gauged from the fact that the port was now easily able to cope with the enormously increased volume of trade that was indicated by these figures. It was not only as an Administrator of the Port that Rangoon was indebted to Sir George Buchanan. Rangoon had for long been threatened by the action of a river two miles broad, which was gradually changing its course, with the inevitable result that eventually the town and port would have been left high and dry, stranded far from the natural estuary of commerce. To avert this catastrophe Sir George designed a scheme which was known as the Seikgyi training wall. It was a great work, and was estimated to cost a million pounds. Sir George carried his design, in spite of a great deal of delay and opposition by Simla experts, with the result that the work was completed within the estimated cost and its stability and success had been established beyond doubt. Now might he venture on a little criticism? Sir George put forward as the best solution of the difficulties of port administration the creation of a Department of Communications to deal with railways, inland waterways and ports, roads being left to the local governments. The object of this proposal was that the policy of ports might be guided in the interest of the Empire. That was a reason that sounded very wise, but if it was examined he thought it would be found to be meaningless. The interest of the Empire in the ports of India was simply and solely that each port should be administered so as to provide for the trade that now passed through it, or that might be expected in the near future to pass through it. It was in nearly all its aspects a local matter. Suppose there had been in existence an Imperial Department to guide the policy of the Port of Rangoon in the interest of the Empire, what more could this department have done in past years than Sir George himself had already done for the Port of Rangoon? Then, again, Sir George proposed that ports should be financed by Government including in their loans the sums required for port development. The existing method was that ports borrowed money in the open market on the security of their revenues. Sir George deprecated the new department bearing any resemblance to the Railway Board, but it seemed to him that it would be the same thing over again. His experience of the Railway Board, gathered from Burma, was that, however promising a railway scheme might be as regards its future prospects, if there was no promise of immediate revenue it was hopeless to get the money to carry it out, because there were sure to be other competing schemes in other parts of India which absorbed all the money available for loan. If the local Government had had the power, which the Port Commissioners had at present, of borrowing in the open market on the security of its revenues, he was sure that Burma would now have twice its existing mileage of railways. He deprecated any such scheme of further centralisation. Especially under the new order of things, when the Government of India would year by year be more Indianised, it would be disastrous to Burma to remove the ports from the control of the local Government and place them under an Imperial department. The ports of a province should continue to be under the control of the Government of the province, which was more directly concerned in their welfare, with less interference than at present from the Imperial

Government. If Sir George's Imperial Department had been in existence in the past, he doubted whether Rangoon would have had the up-to-date port which it now possessed, and he fancied that the estimates of the Seikgyi training wall would still be reposing in the pigeon holes of the Department of Communications.

SIR M. VISVESVARAYA, K.C.I.E., M.Inst.C.E. (ex-Dewan of Mysore), said that in India, as in other countries, it was essential that production should be increased by every means in their power, and the measures most necessary for that purpose were the development of scientific agriculture, irrigation, factory industries, mining, etc. In the sphere of transportation, ports and shipping occupied a similar important position. India was bounded on the north, north-east, and north-west by natural barriers, which had not been pierced or crossed by railways as yet. There was no likelihood of communications being opened in those directions for some considerable time to come, and it might be said that so far as communications with foreign countries went, India was practically an island. Unless ports and shipping facilities were sufficient and efficient, the transit charges for commodities would mount very high, and that was actually happening in India. As a result, foreign intercourse was rendered difficult and the Indian farmer did not get the full benefit of the prices realised in foreign markets for his produce. The trade of India had also suffered in the recent war on account of insufficient port and shipping facilities. The foreign trade of Canada, which had only a population of eight millions, recently exceeded that of India with a population of 315 millions. For those reasons he was in favour of improving existing ports and of opening up more ports. Before he left India, he took some interest in the development of a port at Bhatkal, a small town on the west coast about half-way between Bombay and Cape Comorin. Bhatkal was a port of some importance in the last century, but, on account of territorial rearrangements, it lost that importance, and a forest had grown up cutting off communication between Bhatkal and Mysore. The port was situated at the meeting-point of three territorial divisions, the Presidencies of Bombay and Madras and the Native State of Mysore. The Mysore Government was building railways in that direction, and when these were completed only a link of thirty or forty miles would remain to connect the system with Bhatkal. Several rough schemes for developing the port had been prepared, and one of them had lately been approved by a well-known London firm of harbour engineers. A concession from the Government of India asked for by Mysore, namely, political jurisdiction over some three square miles of land near Bhatkal was required to enable Mysore to construct the railway line and the port. It was hoped that under the new order of things in India it would be possible to make this small concession without which the State would not be able to invest the large sum of money required to promote the scheme. While they were considering port facilities, the importance of shipbuilding should not be lost sight of. As a result of the war, many countries, including the self-governing Dominions within the British Empire, which formerly had no ships of their own, were actively engaged in shipbuilding. They had come round to the view that foreign shipping could not be depended upon in emergencies. It was to be hoped that India would take the same view of her responsibilities. Canada had recently started shipbuilding through Government agency, and had schemes of port development in hand estimated to cost about 50 million dollars. Even Australia, with a population of only five millions, was operating a Government-owned steamship line. The United States Board of Shipping constructed ships and sold them to the public. He thought that there should be three classes of ports in India, namely, Imperial, Provincial and local. The minor ports might be developed by the municipalities or other local authorities concerned, with the aid of grants from Imperial or Provincial funds according to circumstances. It was also necessary to associate shipbuilding with port development under Government auspices for some time at the commencement. If such a policy were adopted, he was sure it would strengthen the economic position of India.

MR. H. S. LAWRENCE, C.S.I., I.C.S. (Commissioner in Sind), said that in regard to Karachi Sir George Buchanan had stated that the financial position was insecure; and he based that view on the fact that the expenditure almost equalled the revenue. Surely it was a first principle of correct budgeting to levy no more taxes from the public than were required to balance expenditure; and every port should be as cheap as possible so long as it met its expenditure. Moreover, Sir George quoted figures which showed that the debt of Karachi was equal to only four years' revenue; while in another paragraph they found that the debt of all ports in India was equal to eight years' revenue. And again while Calcutta and other ports had levied special war taxation, Karachi had levied none. He (Mr. Lawrence) submitted that it was clear that this charge of financial insecurity was based on a misapprehension. Sir George also said that Karachi could not challenge Bombay as a port for passengers and mails, because it did not possess the "amenities" of Bombay. If by "amenities" was to be understood climate, there were few persons with an experience of both cities who would prefer the climate of Bombay to that of Karachi. But if they were to interpret that word as covering hotels and entertainments, it was natural to expect that the supply would not precede the demand. Sir George had described the immense variety of interests with which port authorities were brought in contact. There were not only the shipowners and the merchants who called for despatch and safety in the handling of ships and cargoes; there were also

the military, naval, and railway authorities; there were the passengers and mails; and behind all the governing consideration must always be the welfare of the country served by the port. There were two important omissions: the care of dock labour and the welfare of seamen. Dock labour, with its casual employment now the subject of special inquiry at home, would soon be demanding attention in India. During the war they were on the verge of dock strikes in Karachi more than once. The seamen, both Indian and European, had an indefeasible claim to better consideration than they had yet received. Their interests had been left largely to private charity, and the law which authorised Port Trusts to utilise their funds for their benefit had been almost forgotten. The gratitude of the Empire for the heroism of the Mercantile Marine had been expressed in words over and over again. It was time that the port authorities were urged to make good this gratitude by adequate provision for the comfort and entertainment of these splendid fellows. No better War Memorial for Seamen could be devised. To discharge these numerous responsibilities the Chief Executive authority of a port must bring into harmonious co-operation men who approached the complex problems of daily administration from widely varying standpoints; and he was frequently confronted with a serious conflict of powerful interests. Under his control there were many branches, each with a competent professional head; a naval branch dealing with sea captains and pilots, a port engineer for hydraulics and tidal questions, a dock engineer, a mechanical engineer, a railway engineer, and secretaries for trade and commerce. It was clearly impossible to find a man for this supreme control who could be an expert in all these branches. When Sir George expressed his opinion that a Chairman who was not an expert was in the hands of his Board, and was apt to vote with the most insistent mercantile representatives, he felt bound to state that this criticism did not accord with his experience. While he concurred with the main conclusion of Sir George's paper, time permitted him only to record these items of dissent.

Mr. Ernest Benedict, M.Inst.C.E., desired, as the engineer who had charge of the railway works in Karachi forty years ago, to state that the present two miles of wharf, which enable transports to come alongside and discharge troops, ammunition and goods, just across the wharf into trains, were the development of a wharf 700 ft. long which he put up in 1882 at Keamari. The author was accustomed to carry out things on a big scale, and he was therefore astonished at his deprecating a big scheme for the future development of Karachi, which he himself had adumbrated in the paper as the leading port of India. It did not follow that, because a scheme was big, all of it need be carried out at once; in fact, the present wharves had been added to by degrees. The author had made a great point of the building of elevators. He believed an elevator had been built at Lyallpur in the very centre of the wheat district, but he had never heard anything of its working or whether it was a success or not. From what he knew of the Karachi trade, he was afraid it would be impossible to get the local interests to use an elevator, even if it were there, nor did he see how that would give sufficient additional shipping accommodation, although it might release wagons. If the wharves were filled with ships and another one came in, how would the elevator help to solve the problem? He had never heard of a complaint that ships were detained at Karachi, whereas as a matter of fact the facilities were greater, both for passengers and for goods, than they were at any other port in India, and had been so for years past.

Sir Horace Charles Mules, C.S.I., M.V.O., O.B.E., said that he feared he must plead guilty to being one of the unfortunate individuals at whom Sir George Buchanan had had a rap—a so-called inexpert Chairman, but having served for fifteen years as Chairman of the Port Trust at Karachi, he thought he might be permitted to say that he had a little knowledge of port administration. With regard to the author's remarks on the constitution of Port Trusts, he desired emphatically to say that during his chairmanship of the Karachi Port Trust he had found the mercantile representatives on the Board of the very greatest possible value; in fact, he considered it would be extremely difficult, if not impossible, to carry on the Port Trusts in India without the valuable advice and assistance received from the mercantile community, in whose hands lay the conduct of the whole of the trade which passed in and out of the port. Mr. Lawrence had confuted Sir George Buchanan with reference to the financial position of the Karachi Port Trust, but he would add that since the Trust was constituted they had never borrowed a rupee from Government, that in the first year of the present century the revenue of the Karachi Port Trust was under 8 lakhs of rupees, while in the last year before the war it was 58 lakhs of rupees, and the Reserve Fund had risen from less than a lakh to between thirty and forty lakhs. The policy adopted at the Port of Karachi had been a steady development of the wharfage, and that policy was still being continued. In regard to the author's statement that it was ill-advised on the part of the Karachi Port Trust to proceed with the construction of extensive wharfage, he desired to point out that the great scheme of reclamation now in progress contemplated in the first instance merely the creation of six additional berths for steamers of the largest possible tonnage likely to enter Indian ports and drawing the greatest possible depth of water. He did not think a port which at present enjoyed the possession of only nineteen berths alongside the wharf, one of which was a very small one, could be said to be hurrying to perdition when it was going to con-

struct as a preliminary another six berths. They had also not lost sight of the necessity which might arise in the future for the construction of elevators, but they had for the last ten years persistently pursued the policy of following the trade. Years ago the Government of the Punjab, as an experimental measure, constructed a small elevator at Lyallpur, and the late Lieutenant-Governor of the Punjab, Sir Michael O'Dwyer, wrote to the Karachi Port Trust, and asked if they would construct a terminal elevator for that port. In reply they said they were perfectly ready to meet the demands of trade, provided all were prepared to do their part, and they therefore asked the Governments of the Punjab, Sind, and the United Provinces, whether they were prepared to build the necessary elevators along the railway lines which would feed the terminal elevator. They were met by a "non-possumus." He had gone very carefully into the question of the cost, and found that the pre-war cost of an elevator was £3 10*s*. a ton. Karachi, a seasonal port, dispatched in the course of three months about 1,000,000 tons of wheat and other grains, and if an elevator was erected it must have a capacity of at least 300,000 tons. The present cost of building such an elevator would be absolutely prohibitive, and would throw an additional burden not only on the wheat-growing trade, but also on the wheat-consuming public, which it could not by any possibility bear. At the present time labour in Karachi was sufficiently cheap to render it unnecessary to construct elevators, but the Port Trust had never opposed their construction for one moment, and had always recorded their readiness to construct them when the demand arose. The present system, which had recently been submitted to a recognised expert, would provide for the accommodation of steamers of the largest size, drawing the greatest amount of water, that would be used in Eastern waters. He thought the results achieved, financial and otherwise, at the port of Karachi entitled it to its place as one of the foremost and most go ahead ports of India, and that the Board as at present constituted might be thoroughly trusted to carry out their work to a satisfactory conclusion.

Sir Charles S. Bayley, G.C.I.E., K.C.S.I., Chairman of the Indian Section Committee, desired on behalf of the Society to express its thanks to the Secretary of State for his kindness in attending and presiding over the meeting. The subject of the paper was one of very great importance, and the fact that the Secretary of State had recognised this by his presence had been immensely appreciated. He also desired to move a hearty vote of thanks to the author for his exceedingly interesting and valuable paper, which had provoked an equally interesting and valuable discussion.

Sir Krishna Gupta, K.C.S.I., in seconding the motion, said that everyone present knew what a great interest the Secretary of State took in all matters that concerned India, and his presence that afternoon was an additional testimony to that fact. With regard to the author's interesting and suggestive paper, he happened to come from Calcutta, which apparently had fallen on very evil times. Not many years ago it was the capital of British India, but it had now been dethroned from that exalted position. Calcutta had some little pride left in thinking that it was a great port and commercial city, but after what the author had said it was necessary to speak of it with bowed heads. Sir George Buchanan had told them that the inefficient administration of ports in India was due to the fact that they were generally in the hands of men who had only a fleeting interest in their welfare; they were about to retire and were therefore not interested in the permanent progress of the ports. He was not present to sustain or deny the charge, but in view of the reform scheme and its further development it was to be hoped that Indians who had a permanent interest in the development and progress of their ports would have an opportunity of taking a greater interest in them in the future. The pioneers, the British merchants and others, had done a great deal to develop the resources of India, but their interests were not permanent, and if they were associated with Indians who had a permanent and abiding interest in all that concerned India he thought the very best results might be hoped for.

The resolution of thanks was carried unanimously.

Sir George Buchanan expressed his thanks for the appreciation of his paper, and for the patience with which the audience had listened to it. He would take the opportunity of replying to the criticisms that had been made by means of a written communication to the *Journal*. It was with a certain amount of relief that he found that the "full-blooded and lusty Port Trustee from Calcutta" was not present.

The Chairman said he regarded it as one of the first duties of the Secretary of State to go to all meetings where Indian affairs were being intelligently discussed, in order to obtain new opportunities of serving and new material with which to serve. His only difficulty was that unfortunately time did not permit of a more general fulfilment of this duty.

The meeting then terminated.

Sir George Buchanan, in a written reply to the remarks of the various gentlemen who took part in the discussion, says with reference to Sir Charles Armstrong's comments, it was far from his intention to belittle the value of European representatives on the Port Trusts, that in commenting on the difficulties of an Indian Port Trust he had remarked on the constant changes of personnel, and said that Europeans on the

verge of retirement did not wish to be troubled with schemes which would not materialise until after they had left the country. He did not think that was unnatural, the point being that there were many more retirements in India than in the United Kingdom. He agreed with Sir Charles Armstrong that what was wanted as Chairman of a Port Trust was a man of great administrative power, with big ideas and far-seeing views, but it was not correct that he thought it essential that such men should be sent out from home. He would like to see the Indian Port Trusts so well and strongly staffed that there would always be an officer at one or other of the ports capable of taking the Chairmanship at any port when a vacancy occurred, and thus avoid bringing in outsiders, either from India, often with no port experience, or from home, often with no Indian experience. With reference to the comments of Mr. Lawrence, Mr. Benedict and Sir Charles Mules, on the subject of Karachi, Sir George Buchanan would be the last person to deprecate big development schemes; all he suggests is, that before committing themselves to a big scheme, the Port Trustees should satisfy themselves and the public that it is the best possible project. There is no doubt that Karachi cannot for ever remain the only large grain export port which works without an elevator, and he does not accept without data Sir Charles Mules's estimate of the lowest capacity an elevator should have, to be of any use. Labour will not always be cheap, and the desirability of retaining as a permanency the present system of shipping and landing goods is open to question from various points of view. In the matter of finance, it was the Port Trustees themselves who considered a revenue of 50 lakhs a safe average to depend upon for the next ten years, and if that is the case, it is obvious that with an expenditure varying from 45 to 52 lakhs of rupees there is not much margin to pay interest and sinking fund on a 250 lakh loan. Judging from his own experience he thinks the Trustees are possibly not allowing sufficient margin for the increase of trade. Finally, he wishes to say that he is a great admirer of Karachi, and a believer in its future, but, as already stated, he is of opinion that the whole future of Karachi requires the deepest consideration from the Imperial point of view, and that the problems connected with its development require careful consideration, and possibly special treatment. In reply to the criticisms of Sir Harvey Adamson and others on the proposed Imperial Department to deal with Railways and Ports, he would emphasize the fact that the Government of India and the local governments at present exercise very considerable control without the necessary expert advice to guide that control. His proposal is to retain the Port Trusts and to increase their powers, and to strengthen both their hands and those of the Government of India by the creation of a Department which would encourage port development and exercise an efficient and fatherly guidance. Although it is true that Bombay and some of the other ports have done very well under the existing regime, Calcutta and Chittagong have done very badly, and it would be one of the duties of the new department to keep ports up to the mark and up to date, and where ports in the public interest required development but had no immediate funds, the new department would provide funds by other means than handing over the port to a railway company and allocating funds from the Railway Budget. Further, in the case of a badly managed municipality the Government at times found it necessary to step in and insist on reform, and if this is desirable in the case of a municipality it is much more so in the case of a port. In conclusion, Sir George Buchanan regrets if he has by his remarks offended anyone's susceptibilities. As Chairman for many years of an Indian Port Trust he fully realises their difficulties and the zeal and enthusiasm shown by the staffs at the various ports. Improvement is however possible in every undertaking, and he hopes that his paper will be taken as an honest endeavour to assist in the development of Indian ports by suggesting problems for solution.

Mr. W. J. Good, in reply to that portion of Sir George Buchanan's paper dealing with the Port of Calcutta during the period 1900–14, in which he states "Calcutta remained with folded hands, and was only awakened from its sleep . . . ," writes:—

I think that I cannot do better than give a few quotations from the Report of the Committee which sat in 1914, to which Sir George Buchanan refers, and of which the then President of the Institute of Civil Engineers, Mr. A. G. Lyster, was a member. " . . . they (*i.e.* the Port Commissioners) submitted to Government a scheme based on the principle that all future requirements of the trade of the Port should be provided for as near as possible to Calcutta, the centre of a very considerable proportion of that trade. It comprised the acquisition of land adjacent to the existing docks for the gradual construction, as the demand arose, of a new dock system with independent entrances, riverside berths on the available frontage at Garden Reach, and the provision of improved and extended facilities for the reception, distribution, and despatch of rail-borne traffic. The proposals of the Commissioners were approved by the local Government; the administrative sanction of the Government of India was received, and an area of some 5,500 bighas has been acquired. In the meantime the accommodation of the Port has not stood still pending the inception of this larger scheme of extensions. Apart from the improvements at the jetties, which we have already described, at the docks four new berths for general produce have been provided, and another similar berth is under construction; while for export of coal one additional berth has been constructed. Concurrently with these extensions the warehousing accommodation for both imports and exports has been

very largely extended, and numerous lesser improvements have been carried out. While these additional berths represent a very substantial increase on the accommodation for shipping available in 1906, an increase in the case of the jetties of 50 per cent. and at the docks of 33 per cent. (excluding the coal berths), it is clear that, even with these extensions, the rapid expansion of the trade at Calcutta during recent years has outgrown the accommodation. It is therefore now proposed to enter upon the first portion of the greater project contemplated in the proposals of 1906, namely, the construction of the riverside berths at Garden Reach, the entrance to the new dock system, and the construction of a new dock junction railway yard, including the re-alignment of a portion of the Budge-Budge branch of the Eastern Bengal State Railway. The Commissioners have supplied us with a plan to show the general basis on which they contemplate that future extensions should be made. We are of opinion that the lay-out of the scheme is generally suitable, and that it will ensure an ample margin for the expansion of trade which is likely to take place within any period that can reasonably be foreseen. We recognise that in the past the Port Commissioners have developed their property generally speaking on sound lines, and with a zealous regard to the best interests of the port. We consider that the schemes for future development which have been placed before us are on the whole well calculated to foster that development. The main criticism to which the conduct of the port affairs is open is that the inception of these schemes was delayed until the great increase of trade during the last two years showed only too conclusively how urgently they were required. We further wish to take this opportunity of recognising the eminent services which Sir Frederick Dumayne has rendered to the Port of Calcutta during his tenure of office as Vice-Chairman of the Port Commissioners. Without the substantial improvements which have been effected in every branch of the port administration during his incumbency of the post, the general expansion of trade which has taken place, and the corresponding growth in the revenues of the Port Trust, would not have been possible. The schemes of extension, to which we have just referred, were initiated under his auspices, and that their inception is now possible is due to his foresight and to his grasp of the situation. Had the decision rested with Sir Frederick Dumayne, it is probable matters would by now have been further advanced, but we believe that his anticipations of the future growth of the trade of Calcutta were generally regarded as too optimistic. In the result they have been completely justified."

To summarise, in the period 1900-14 Calcutta, "with folded hands," in addition to the accommodation available in 1900, provided, acquired, or had under construction for the accommodation of the increase in her trade: (*a*) Nine additional berths for ocean-going vessels fully equipped with cranes, etc.; (*b*) 2,400,000 square feet of covered area for handling and storing goods; (*c*) 1,800 *acres* of land for new docks, railway yards, and storage depots; (*d*) two powerful dredgers for the river channels and one for the port. At the same time reductions in charges were made amounting to over 100 lakhs of rupees over the whole period. During the war it was practically impossible to proceed with new works, but the Commissioners have provided two new berths, and hope by the end of 1921 to have four berths for ocean-going vessels and 1,080,000 square feet of covered storage room additional to the accommodation available in 1914. They are also just about to embark on a new dock scheme which will finally give at least forty additional berths. In the preparation of the plans for this scheme the Commissioners' Engineering Staff have had the advantage of consultations with their Consulting Engineer, Mr. J. Angus, and with Lieut.-Colonel Cartwright-Reid on the spot. To other points raised by Sir George Buchanan, I hope to reply fully at another time.

Sir George Buchanan, in reply to the written communication from Mr. W. J. Good, says he did not intend his remarks as to Calcutta remaining with folded arms, and being awakened from its sleep, to be taken so very literally. Of course the port was kept going, and a certain number of works were carried out, but the fact remained that, at the beginning of the war, Calcutta was the only first-class port in India starting a great scheme of extension instead of finishing one. Sir George Buchanan observes that Mr. Good's quotations are really confirmatory of the statements in his paper. For instance, the Committee's remark to the effect that, "the main criticism to which the conduct of the port affairs is open is, that the inception of these schemes was delayed until the great increase of trade during the last two years showed only too conclusively how urgently they were required." Further on, and again quoting from the 1914 Committee report, Mr. Good says, with reference to the delay to carry out works at Calcutta: "Had the decision rested with Sir Frederick Dumayne, it is probable matters would by now have been further advanced, but we believe that his anticipations of the future growth of the trade of Calcutta were generally regarded as too optimistic. In the result they have been completely justified." Sir George Buchanan pointed out the disadvantages of dual control in port administration, and no doubt had it not been for the dual control of Chairman and Vice-Chairman Sir Frederick Dumayne would have carried his point. There was considerable opposition at Bombay to the Alexandra Dock scheme initiated by Sir Walter Hughes, but he as Chairman and Chief Executive Officer combined, was strong enough to frame his policy and carry it through, in spite of opposition, with the result that his great dock scheme was finished and opened by the Viceroy in 1914.

POULTRY AND EGG PRODUCTION IN CHINA.

The poultry and swine industries are by far the largest of the live stock industries in China, the former being the most important. Nearly every family in the villages in all parts of China raises fowls, and many keep one or more brood sows. Professor King, in his interesting book "Farmers of Forty Centuries," states that in Japan there are 16,500,000 fowls, or about one fowl for every three persons in that country. The number of fowls raised to maturity in the United States in 1911 was 300,000,000, or three for every person. There are several varying estimates of the number of fowls in China. Striking a medium between the number in Japan and in the United States, China would have one bird for each inhabitant, or approximately 400,000,000, and, judging from the number of fowls seen everywhere, this is not an overestimate. Further, the Chinese are heavy users of poultry and eggs, and probably consume as much, if not more, per capita than does the average American. Despite the heavy consumption the supply not only keeps up with the demand, but is enough to permit a fairly large export of poultry and poultry products.

According to the Japanese authorities, the average egg production per hen in Shantung is eighty-four, which is high compared with other countries, the average in the United States and Canada being about seventy-five. It is also higher than investigations so far have shown it to be in Canton. In 1918 a production experiment lasting a year was conducted with thirty hens, of the common mixed variety seen everywhere in the villages of that region. They were given the feed commonly fed to fowls by the villagers. The lowest record was fourteen, the highest 104, and the average for all seventy-two. The higher production per hen in Shantung Province is probably due to the feed used in that region, which consists principally of beans, whole and cracked. Beans contain a high percentage of protein and make an excellent food for egg production.

The estimated total value of poultry and eggs produced each year in China is about £84,000,000. As mentioned above, these are not all consumed in the country. In 1917, for instance, shipments of eggs (fresh and preserved) from China totalled 57,987,000 lb. valued at £400,000, and of egg albumen and yolk 54,002,000 lb. valued at £2,590,000. The fresh eggs are exported chiefly to Hong Kong and Japan, and the dried product to Great Britain, Spain, and the United States. Before the war a considerable portion of the dried product went to Germany.

According to a report by the United States Consul at Canton, there are a number of breeds of poultry native to China, some of which have become very popular in America and Europe. The Cochin breed of Swatow, of which there are two varieties in China, the White and the Buff, and the Black Langshan, known in China as the Black Shanghai, are Chinese breeds that are common in most parts of the world where attention is given to poultry production. These are heavy breeds and are raised especially for meat, although they are also good layers of large eggs. The hens weigh from four to six pounds and the cocks from five to nine pounds.

Two other distinct native breeds are the Silkie and the Frizzle. Literature written a thousand years ago mentions these peculiar breeds. These fowls are not very common, the reason given being that they are difficult to raise, and that they are poor layers. Their meat is considered by the Chinese as having medicinal value, and is eaten for a tonic. The skin of the Silkie is dark blue, and a thin, black film surrounds the bone. In both breeds the bill and the exposed skin on the head, feet, and legs are deep blue. The Silkies have downy feathers, white being the most common colour. The Frizzles are black, and have peculiar feathers which curl back on themselves. Their price is usually twice that of ordinary fowls.

Ducks and geese are raised in large numbers in many parts of China. The numerous waterways, both natural and artificial, afford ideal conditions and cheap feeding for these classes of poultry. While there is no recognised breed of ducks in Southern China, the White Peking duck of North China has become established the world over as the best variety of meat duck. It was introduced into England in 1873.

In the region of Canton and most parts of Southern China the common duck is a small dark grey or white and grey bird, weighing from 3 to 5 lb. It is a very good eating duck, and is very popular, used either fresh, roasted, or dried. In the northern part of Kwantung a grey duck weighing from 8 to 12 lb. is found. Ducks of this breed are very good layers and the meat is said to be excellent.

Two of the world's best varieties of geese, the Chinese white and the Chinese brown, have their origin in China. To-day they are found in most parts of China, America and England. The Chinese geese are the most beautiful of all varieties, and are in demand for ornamenting lakes of public and private parks. They are also superior for practical purposes, outrivalling all other breeds and varieties in egg production and in the quality of their meat. Their bodies are plump and round, and they produce a good quality of feathers and down. They are medium in size, mature specimens weighing from 10 to 14 lb.

In general appearance the Chinese geese have long necks, carried very upright, and a large orange-coloured round knob or protuberance on top of the bill at its base. The larger the knob the better. In the south a small grey variety is common. It is not as ornamental as the white and grey species but has meat of good quality. The protuberance on the base of its bill is coloured black.

Some chickens are hatched in the natural way, but by far the greater number are hatched in large incubator shops throughout the country. In the vicinity of Canton there are fifteen Chinese incu-

bators, which hatch an average of 2,800 chickens and ducks a day during the hatching season from March until October. Estimating that half of these grow to maturity, nearly 5,000,000 fowls are supplied each year to Canton and surrounding villages by the incubator shops. The Chinese method of incubating eggs is economical and efficient when it is desired to produce poultry in large numbers, and it is strange that the method has not been adopted for hatching eggs on a commercial scale in other countries.

Wuchow, on the West River, is probably the largest poultry producing centre in the south. The customs returns for the year show that after supplying the local demand, that city exports an average of 2,500,000 birds a year to Macao and Hong Kong. Nanking, Hankow, and Young Kong rank also among the large poultry-producing centres of China.

The methods for applying heat in the Chinese incubators are similar to those used by the Egyptians 4,000 years ago in similar incubators, ruins of which still exist in the Nile River Valley. On the first day the eggs are thoroughly warmed to the proper incubating temperature, of 103° F. or a little less, by placing them in a brick, oven-like room, usually 6 feet deep, 12 feet long, and 10 feet high. The eggs are placed in baskets arranged on shelves around the walls of this room, each basket holding 200 or 300 eggs. In the larger shops as many as forty or fifty of these baskets may be found in this oven at the same time. Heat is furnished by burning charcoal in earthenware pots placed on the floor of the room. Sometimes baskets of eggs are placed in large stone jars and a slow charcoal fire is kept burning continuously against or underneath the outside of the jar. This method is largely used at Shanghai, Hankow, and other places in the north, where the climate is cooler and constant application of heat is necessary through most of the hatching season. Another method used in Honam is to place the eggs on the roof of the shop in warm sunlight until they are thoroughly heated through to the right temperature.

After the eggs have been heated to the proper temperature, either in the oven or in the sun, they are placed in cylindrical baskets about 30 inches deep and 20 inches in diameter. Each basket holds about 1,000 eggs. The walls of the basket are about 1½ in. thick and are made of firmly packed rice-straw held in place with wicker or bamboo both inside and outside. The baskets are lined with a heavy grey paper, somewhat like asbestos. This paper and the basket itself are thoroughly warmed before putting in the eggs, which are arranged in layers, each layer being separated by a piece of cloth about 2 ft. square. Twice a day the eggs are changed from one basket to another. The operator simply grasps the corners of the cloth, and in so doing the eggs naturally tumble together in a heap in the centre. He then transfers it with the eggs to another basket. This method takes the place of the slow method of turning eggs used with modern incubators, and is most efficient, requiring only about one-tenth the time. Transferring the eggs from one basket to another by this method also gives the airing considered necessary for the production of strong healthy chickens.

The eggs are usually kept in the baskets fourteen days, and are then transferred to large trays, 6 ft. wide, 18 ft. long, and 3 in. deep. Each tray holds about 10,000 eggs. The bottom of the tray is lined with the same heavy paper with which the baskets are lined. The eggs are also covered with this paper, with blankets, or with both. The amount of coverings depends, of course, on the weather and the period of incubation. In warm weather no covers are needed during the last two or three days. Just before hatching time, the number of eggs in the trays is reduced to one layer, and an empty space of about two feet is left at one end toward which the eggs are turned or rolled twice a day.

The eggs are candled twice, usually on the third and seventh days, and all infertile eggs are sold, so that there is very little loss through unhatched eggs. Throughout the incubation period careful watch is kept over the temperature. No thermometer is used, but the operator raises the lid or a blanket, removes an egg and presses the large end against a closed eyelid where the skin is very sensitive to temperature. Long practice has taught him to judge differences in temperature quickly and accurately. The men sleep in the room with the eggs, or in adjoining rooms. Someone is on duty constantly, examining and regulating each basket or tray according to its individual needs.

The chickens when hatched are placed in circular bamboo trays about 3 ft. in diameter and 8 in. deep. They are ready for sale as soon as dry. The hatching percentage usually runs about 75 per cent. of the fowl eggs and about 90 per cent. of the duck eggs. This average hatch is quite fair, and, with better sanitation, ventilation, and construction of buildings, and the use of thermometers, this method of hatching eggs on a large scale would be far more economical and efficient than hatching chickens in any of our so-called modern incubators.

In Canton the eggs are usually purchased at two cents (local silver) each and sold at from four to six cents each, the price depending on the demand and the season. The chickens and ducklings are usually contracted for in large lots by chicken dealers and large duck feeders. Large chicken-feeding farms are not common, but there are many duck farms on Honam Island, feeding from 5,000 to 50,000 ducks at one time. These are purchased from the commercial incubators when about a day old in lots up to 40,000, and fed for about 100 days, when they are sold in the Canton markets.

THE PORTUGUESE CORK INDUSTRY.

According to a report made by the Association of Corkwood Manufacturers of Portugal, the total world production of corkwood is estimated at

396,832,000 lb., of which 45 per cent. is produced in Portugal, 30 per cent. in Spain, 5 per cent. in France and Italy, and 20 per cent. in Algeria and Tunis. For the present, writes the United States Consul-General at Lisbon, Portugal is the largest producer of corkwood, and probably will maintain its position for several years more. In some districts of Portugal the quality of the corkwood is superior to that of other countries. The forests in Algeria and Tunis, the exploration of which began recently, may produce larger quantities of corkwood in the future. The same is true of Morocco, whose extensive forests will enable it to become the first producing country of corkwood in the world.

The greater part of corkwood is used in manufacturing cork stoppers and cork discs. Cork waste is employed in making linoleum, for which purpose virgin corkwood is also used.

The principal importers of Portuguese corkwood are: England, which imports ready-made cork stoppers, France, South America, United States, and Germany. They import chiefly corkwood, and the cork stoppers are made in the importing countries. Portugal manufactures 25 to 30 per cent. of its corkwood into cork stoppers; Spain, 70 to 80 per cent.; and France, the whole continental and a small part of colonial production. The small percentage of cork stoppers produced in Portugal is due to lack of modern machinery, and also to heavy duties on this product in the consuming countries.

NOTES ON BOOKS.

THE HARDWOODS OF AUSTRALIA AND THEIR ECONOMICS. By Richard T. Baker. Sydney: William Applegate Gullick, Government Printer.

It is roughly estimated that the number of species of trees growing in Australia is about five hundred, and of these the *genus* Eucalyptus accounts for some two hundred. The Eucalyptus covers an enormous area of the continent—hundreds of thousands of square miles; all the timbers of this family are valued for their hardness and weight, and they are remarkable for the rapidity of their growth. The author quotes the case of an Australian gum tree, which made as much hardwood in twenty-four years as an English oak in two centuries. This is enough to show what enormous potential wealth Australia possesses in her timbers.

The present volume has been designed by the author, who is Curator and Economic Botanist, and Lecturer on Forestry in the University of Sydney, to make known to Australians in particular and to the world in general the qualities of the various hardwoods which flourish on the continent, and is especially written for architects, saw-millers, engineers, cabinet-makers, and foresters. The first part deals with the physical properties of timbers, a particularly interesting section of which is concerned with their comparative combustibility. Now that naval construction, on a large scale, is being undertaken in Australia, it is important to find woods of low combustibility for internal use in ships of war, and Australia is fortunate in having a large supply of such timbers. A list of woods arranged in the order of their fire-resisting qualities will be found exceedingly useful in this connection.

Part II. contains descriptions of the various species of hardwoods in botanical sequence. This occupies 350 pages. A great number of the sections are illustrated with coloured plates which give an excellent idea of the appearance of the various timbers, both as to shade and grain.

Part III. is technological, and deals with the uses of the woods in architecture, engineering and for general purposes. Some space is devoted to the problem of seasoning, both by natural processes and by kiln-drying. Various methods of preserving timber are discussed, and a number of photographs are given illustrating the various uses of timber in building and fitting railway cars, bridges, wharves, jetties, and in the manufacture of furniture. The book has been compiled with much care, and contains a great amount of information, which should go far to popularise the use of Australian timbers.

GENERAL NOTES.

CULTIVATION OF WHEAT IN FRANCE.—A first meeting of the Comité National du Blé has recently been held in Paris, under the auspices of the Minister of Agriculture. It was decided to take immediate steps to impress upon the farmers, and the rural population generally, the necessity of immediate action respecting the production of wheat in France. It is proposed in the first place to collect all available data on the subject, and to disseminate it amongst the farmers and agricultural population generally, and to organise local and departmental competitions throughout the country. It is estimated that at the present time the total area under wheat cultivation in France does not exceed 4,800,000 hectares, or say 11,816,000 English acres, as compared with 5½ to 6½ million hectares (13,545,000 acres to 15,735,000 acres) under wheat before the war. This gives an average yield of 12 quintals per hectare (4·86 quintals or 18 bushels per acre). It would be necessary to increase this to at least 15 to 16 quintals per hectare, in order to approximate the average yield obtained in other countries. Such results might be obtained by a better system of tillage, the use of manures and selection of grain for sowing, in fact, by the best known methods of cultivation.

CARBORUNDUM.—Corundum is an extremely hard mineral used for polishing, and among the coloured varieties are the precious gems, sapphire, oriental ruby, topaz, emerald, and amethyst. Carborundum is an abrasure, and, with the possible exception of the diamond, is the hardest substance known. It is made of carbon and silicon combined by reduc-

tion in an electric furnace, the two thus fused and united becoming an entirely new compound, with new properties. This new abrasion is produced as a crystal of great hardness and is put on the market in the shape of grains and powders; made into wheels for grinding and polishing, formed into cutters for smoothing pottery and porcelain; shaped into bricks and blocks for dressing and smoothing marbles, and fashioned into more delicate instruments for the use of lapidaries, dentists, etc. The manufacture of carborundum requires enormous heat—6000° to 7000°, which can only be obtained in the electric furnace. The corundum plant, the only one of the kind in the world, stands on the banks of the Niagara River, a close neighbour to the great stone building where the Niagara power is generated and from which it obtains the force which it uses to fuse the new compound. Corundum is plentiful in India, Ceylon and Burma, and is related to the diamond, for the diamond is produced by a combination of great heat and pressure. The great heat is already an accomplished fact; possibly in the near future the great pressure may also be obtainable.

PUBLIC AIR SERVICE BETWEEN NICE AND NIMES.—A regular service by the air route between Nice and Nimes has lately been established by the Compagnie Aerienne Française. The service, for the present between the two places, is bi-weekly. Leaving Nice and Nimes on Mondays and Thursdays at 7.30 a.m. and 3.30 p.m., the journey is accomplished, including a stoppage at Avignon, in two hours. Four avions of the A.R. type, of 200 h.p. each, are at present employed for this service.

MEETINGS OF THE SOCIETY.

INDIAN SECTION.

Friday afternoon, at 4.30 p.m.:—

JUNE 18.—SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.) The RIGHT HON. LORD MESTON, K.C.S.I., LL.D., will preside.

CANTOR LECTURE.

Monday evening, June 7th, at 8 p.m. (lecture postponed from April 26th):—

WALTER ROSENHAIN, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy, National Physical Laboratory, "Aluminium and its Alloys." (Lecture III.)

Syllabus.

Special Uses of aluminium alloys—Castings for automobile and aeroplane parts—Castings for aero-engines—Pistons and piston alloys—Properties at high temperatures—Automobile and aero-cylinders—Other engine parts—Structural uses—Rigid airships, aeroplane spars, and wing-coverings—Possible future developments.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 31 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. A. Howard, "The Improvement of Crop Production in India."

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. J. A. McDowall, "The Meaning of the Aesthetic Impulse."

Farmers' Club, Central Hall, Westminster, S.W., 4 p.m. Dr. E. J. Russell, "Farmyard Manure: its Making and Use."

TUESDAY, JUNE 1...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Anglo-Russian Literary Society, Imperial Institute, South Kensington, S.W., 3 p.m. Mr. A. White, "England's Bounden Duty and Gratitude to Russia."

Royal Institution, Albemarle-street, W., 3 p.m. Major C. E. Inglis, "The Evolution of Large Bridge Construction." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Dr. B. Malinowski, "The Economic Pursuits of the Trobriand Islands."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Dr. G. M. Vevers, "Report on the Entozoa collected from animals which died in the Gardens during the past nine months." 2. Professor R. T. Leiper, "Exhibition: Experimental transmission of some Helminth infections." 3. Dr. W. T. Calman, "Notes on Marine Wood-boring Animals.—I. The Shipworms (*Teredinidæ*)." 4. The Secretary, "Notes on an African Trip."

WEDNESDAY, JUNE 2...Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Professor F. M. Simpson, "Santa Sophia and the Mosques at Constantinople and Brusa."

Public Analysts, Society of, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. H. D. Richmond, "The Estimation of Nitroglycerine." 2. Mr. R. L. Morris, "The Perchlorate Method for Potash." 3. Mr. E. R. Dovey, (*a*) "Apparatus for Evolution Methods of Analysis"; (*b*) "An Improved Form of U-Tube."

THURSDAY, JUNE 3...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. R. Swainson-Hall, "Exhibition of Fifty drawings of the Oil-palm, *Elæis guineensis*." 2. Mr. A. Whitehead, "Objects observed in the Neighbourhood of Basra, during the War." 3. Professor W. J. Dakin, "Whaling in the Southern Ocean."

Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. M. O. Forster and W. B. Saville, "Studies in the camphane series.—Part XXXVIII. The cyanohydrazone of camphorquinone." 2. Mr. R. G. Fargher, "Arsinic acids derived from guaiacol and veratrole." 3. Messrs. G. T. Morgan and D. C. Vining, "Diphenylarsenious chloride and cyanide. (Diphenylchloroarsine and diphenylcyanoarsine)." 4. Messrs. F. Challenger and A. E. Goddard, "Organo-derivatives of bismuth.—Part III. The preparation of derivatives of quinquevalent bismuth." 5. Mr. J. N. Ray, "Modification and extension of Friedel-Crafts' reation.—Part I." 6. Mr. F. Arnall, "The determination of the relative strengths of some nitrogen bases of the aromatic series and of some alkaloids." 7. Mr. J. C. Ghosh, "The electrical conductivity of pure salts in the solid and fused states: determination of the activity coefficients of ions in solid salts." 8. Messrs. W. J. Sanderson and W. J. Jones, "Anethole as solvent in the cryoscopic method of determining molecular weight."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. Archer, "Dreams, with special reference to Psycho-Analysis." (Lecture II.)

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Dr. W. M. McGovern, "The Philosophy of Japanese Buddhism."

FRIDAY, JUNE 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian and Colonial Sections.) Sir John Cadman, "The Oil Resources of the British Empire."

Royal Institution, Albemarle-street, W., 9 p.m. Sir Ronald Ross, "Science and Poetry."

Philological Society, University College, W.C., 5.30 p.m. Dr. H. Bradley, "Dictionary Evening."

SATURDAY, JUNE 5...Royal Institution, Albemarle-street, W., 3 p.m. Dr. Y. H. Jeans, "Recent Revolutions in Physical Science—(II.) The Theory of Quanta."

Journal of the Royal Society of Arts.

No. 3,524. VOL. LXVIII.

FRIDAY, JUNE 4, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JUNE 7th, at 8 p.m. (Cantor Lecture.) WALTER ROSENHAIN, B.A., D.Sc, F.R.S., Superintendent, Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, "Aluminium and its Alloys." (Lecture III.)

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

MONDAY, MAY 31st; SIR ROBERT W. CARLYLE, K.C.S.I., C.I.E., in the chair. A paper on "The Improvement of Crop Production in India," was read by MR. ALBERT HOWARD, C.I.E., M.A., A.R.C.S., F.L.S., Imperial Economic Botanist to the Government of India.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 21st; LORD LONDONDERRY, K.G., M.V.O., in the chair.

THE CHAIRMAN, in introducing the reader of the paper, said that Air-Commodore Maitland was one of the original pioneers of the flying service. In 1908 he travelled from London to Russia—a distance of 1,117 miles—by air balloon in 31½ hours. He had the misfortune to break both his legs in an accident on Salisbury Plain to an aeroplane that had been built for him, the aeroplane being subsequently bought by the Government and being the first British-built aeroplane, with the exception of Colonel Cody's machine, bought by the War Office of this country. In 1910 Commodore Maitland was posted to a balloon school at Farnborough, and joined the Air Battalion in 1911. On the formation of the Royal Flying Corps he was given the command of the No. 1 Squadron of Airships, and commanded the early Army airships—the "Beta," "Gamma," "Delta" and "Eta." He was transferred with the Army airships to the Navy in 1914, and had been closely connected with their development ever since. His last exploit was to cross and re-cross the Atlantic in the R 34. The record of Commodore Maitland was therefore second to none in the Air Service, and the thanks of the country were due to such men for the Air Service as it existed at the present time, and for the future developments which were certain to be brought about.

The paper read was—

THE COMMERCIAL FUTURE OF AIRSHIPS.

By AIR-COMMODORE E. M. MAITLAND, C.M.G., D.S.O., A.F.C.

INTRODUCTORY REMARKS.

I am very glad indeed to have the opportunity of addressing the Fellows of the Royal Society of Arts this afternoon on "The Commercial Future of the Airship."

A great deal has been said of late both in the press and elsewhere on the many uses to which the aeroplane can be put for commercial purposes, but very little has as yet been said about the airship or lighter-than-air side of aerial development. It is my object therefore this afternoon, in the short time at my disposal, to put before you as briefly as possible some of the undoubted advantages which the airship can claim to possess over the existing forms of transport for commercial purposes.

There is a further reason why I welcome this opportunity. The Royal Society of Arts has always taken the keenest interest in furthering and generally assisting the advancement of every department of science in connection with the Arts, manufactures, and commerce of this country, and the confidence and support of its Fellows will go far in helping on the ultimate progress of both the lighter and heavier-than-air branches of commercial aerial development.

Introduction.

The airship has two distinct uses—service and commercial.

The chief service functions of the airship are, broadly speaking, extended and fast patrol, convoy and scouting duties, for which the rigid and non-rigid airships each have their use.

The commercial function of the airship is rapid long-distance transport, and for this purpose the rigid airship is the more suitable type. It is with the commercial future of the rigid airship that I propose to deal to-day.

A question of great practical importance in the preliminary consideration of airships is the interchangeability between the service and the commercial airship. The airship, although already developed to the stage of great utility both for service and commercial purposes, is not yet highly specialised, and its rapid conversion from one use to the other is a matter of comparative ease. The hull in both types will, for many years to come, be the same, and it is, broadly speaking, merely a matter of replacing the commercial accommodation with bombs, machine-guns, etc., to convert the commercial rigid into a most efficient service airship. This interchangeability is far more marked than in sea-going vessels. The airship of to-day, so far as its adaptability is concerned, should be compared to the sailing vessel of Elizabethan time, ready at her country's need to become a ship of war and capable of as rapid conversion. This question of the interchangeability of the service and commercial airship is of extreme importance, as on it depends the logical and economical method of future development.

The close association between the Navy proper and the mercantile marine has been proved beyond question an unqualified success in the Great War. Many of the auxiliary vessels, from mine-sweepers to auxiliary cruisers, which were previously anything from trawlers to liners, were of extreme war value. There is no doubt that the policy of a Royal Naval Reserve saved the country considerable expense during peace time, by allowing the naval forces in war time rapidly to expand to a strength which would have otherwise have been impossible. An almost exact parallel can be drawn in the case of the airship. The number of surplus air personnel not required in peace, but of vital necessity in the event of war, can be kept economically in training by the existence of a commercial airship service. Economy will be essential in all matters for many years to come, and I hope I have made it quite clear that the necessary reserve of airships and personnel to meet the exigencies of war can be economically provided by a commercial airship fleet.

Development and Effect of Transport and Communication.

Everything in civilisation ultimately depends on transport and communication, which may be termed the machinery of civilisation, and if civilisation is to progress, transport and communication must be developed.

The study of the effect of transport and communication on history is of absorbing interest, both in indicating the line along which they should be developed in the future, and the benefits humanity may expect to obtain. If ancient history is studied from this point of view, the almost mathematical relation between size of empire and ease of transport and communication becomes apparent. Probably, the most outstanding example is that of the Roman Empire, and the gigantic development in road transportation achieved during its existence.

An example of the effect of transport and communication upon history in more recent times is the difference between the effects of the American War of Independence and the Boer War. In the first case, much bloodshed and bitterness of feeling between Great Britain and America resulted, taking over a century to heal. In the second case, twelve years after the fighting ended, South Africa was one of Great Britain's most loyal partners in the World-war.

The two countries America and South Africa are practically equidistant from Great Britain. The statesmen of to-day are presumably no wiser and greater than those of two hundred years ago. I say this with the greatest diffidence. The great factors which have changed are transport and communication. Slow and difficult communications caused misunderstanding. Rapid and easier communications led to understanding and mutual adjustment.

Transport has similarly altered the whole character of war. Wars began as small club or bow-and-arrow affairs between neighbouring villages which, as transport facilities improved, joined themselves into states and countries, thus extending the magnitude of their wars. Almost invariably wars, in the last thousand years, have been waged between countries and not between isolated parts of a country, culminating in the World-war.

Looking into the future, history thus seems

to indicate that as civilisation and the machinery of civilisation—transport and communication—develop, some form of central government will ultimately arise which will control the whole world. At the present time, however, it is true to say that no stable form of central authority, whether it be a League of Nations or anything else, can be maintained unless existing transport and communication facilities are considerably improved.

Limitations of Existing Means of Transport.

Just as in the case of an airship, sea-going vessels increase in performance with increase in size, and it is seen that between the great centres of population, notably between America and Europe, where high speed transport is in great demand, the largest liners are used to meet the exacting requirements of high speed and long distance.

To build a liner with the necessary speed for the Transatlantic service, it is essential to provide a very large hull to carry the powerful engines and large amount of fuel required. Owing to the necessarily very large size of these ships, an enormous number of passengers must be carried, so great a number, in fact, that it is impossible to operate these large liners at a profit anywhere except between the very greatest centres of population. Between centres of lesser population there would not be sufficient demand for the large amount of comparatively expensive accommodation.

This limitation is illustrated in the case of the service between this country and Australia. Recently, owing possibly to the advent of aircraft with their high speed, a determined effort was made by Australia to shorten the time of passage between Australia and this country. Apparently the steamship companies are quite unable to provide any material improvement in this direction, as they point out that to produce such improvement it would be necessary to construct ships of such a size that they would be out of proportion to the volume of traffic.

In the case of airships of the very largest size contemplated, the number of passengers, mails, etc., carried would be so small compared with large liners that they could be run over routes where the traffic would not warrant the use of these very large liners.

It is, therefore, on the main sea routes that the airship will have its great opportunity, and I hope to show later in the paper that it can operate on such routes at commercial prices.

Successful competition between aircraft and existing means of land transport is a much more difficult matter than over sea, owing to the higher speed of land transport; and though ultimately aircraft may compete successfully for the most rapid transport requirements, it is unlikely in the near future that air transport will be a serious rival to the existing forms of land transport in developed countries.

For routes over both land and sea combined, aircraft have a distinct advantage, owing to the time wasted in changing from train to ship. Over this type of route commercial aerial activity was, as we all know, first instituted in the case of the London-Paris and London-Brussels aeroplane passenger and mail services.

The Need for High-speed Transport.

It cannot be too strongly emphasised that the unit in life is time, not distance; and the distance between two countries is in practice measured by time. Out of the six main factors in transport, the claim of aircraft for an assured future is based on speed—that is, reduction in the time taken by transport.

Transport is governed by six essential factors:—(1) safety; (2) regularity; (3) carrying capacity; (4) comfort; (5) speed; (6) cost.

The relative importance of these factors varies according to the special object in view, and even similar goods transported over the same route may require different types of transport.

The state of the existing means of transport is a vital consideration in developing any new form of transport. To compete with the existing forms of land transport, where goods can be conveyed at sixty miles an hour and over (varying with the state of the development of the country), the speed of any new type of transport obviously must be greater than is necessary to compete with sea transport where the present speed is less than half as fast as on land. Trans-shipment from train to surface craft still further reduces the mean speed of existing transport and favours air transport.

Meteorology and the Choice of Airship Routes.

The choice of airship routes depends so very largely on the prevailing weather conditions and position of the permanent winds that the two subjects must be dealt with together.

I would like to emphasise the importance of accurate meteorological information for all forms of aerial transport. Winds of 40 miles per hour will often be encountered. These will

usually be local in area and will vary greatly in force and direction at different heights above the ground, and if accurate meteorological information is available these winds can frequently be used to assist the airship instead of constituting a hindrance. If full use is made of these winds, both in regard to original choice of routes, and in the actual flying over these routes, the speed made good over the ground can be made to exceed the actual air speed. As meteorology and our own flying experience develop, the winds should ultimately become less of an enemy and more of a friend.

Winds may be divided into two classes—permanent winds and variable winds. The permanent winds are the more important in original choice of routes, and consist chiefly of the trade winds and the westerly drifts. Generally speaking, the winds just north or south of the Equator are easterly and the winds near the poles westerly, so that a ship flying east would endeavour to choose a route in latitudes from 15° to 30° north or south, and when flying west in latitudes between 45° and 60°.

In the chart on the screen showing proposed airship routes of the world this tendency is easily seen. Thus, the route from England to Australia crosses the easterly winds practically at right angles, and turns east from the Cape, making use of the permanent southern westerly drift, or "roaring forties." The return journey is made nearer the Equator to use the easterly trade winds or easterly slants. The Atlantic route is similarly dealt with.

There are also many other less important permanent winds and also seasonal winds, which can be made use of, and will slightly modify the routes during different periods of the year.

The variable winds are the winds which are directly due to depressions, and can only be used provided accurate meteorological information is available. The ability to use these variable winds depends largely on the speed of the airship, as the pilot will often find it necessary to push through a narrow belt of strong wind in order to gain the advantage of a favourable wind later.

As mentioned later, electrical storms form a potential danger to all forms of aircraft, but as the area in which such disturbances are prevalent can be very accurately charted, the routes will be chosen so as to avoid these areas and thus reduce this danger to a minimum.

Reliable weather forecasts necessitate a large number of accurate observations being taken over very extended areas, and to run an organisation especially for this purpose would be extremely costly. If, however, arrangements were made for all sea-going ships fitted with wireless, also the various shore wireless and cable stations throughout the world, to take and transmit meteorological readings, it would probably be possible, in time, to organise an adequate meteorological service for little cost, special meteorological stations only being required in a few isolated positions.

Commercial Capabilities of Airships.

Having dealt very briefly with the fundamental aspects of sea routes, land routes, and routes over both sea and land, I now propose to consider the capabilities and limitations of airships with regard to the essential transport requirements.

Safety.—This term must, owing to the nature of all forms of transport, be purely relative. Even in the most "safe" form of transport, there is always some small risk. The airship is definitely the safest method of air transport, and if the statistics are studied for the pre-war commercial airship flying in Germany, the very extensive war flying of the German Zeppelins, and the 2,500,000 miles flown by the British airships during the war, it will be seen that, excluding enemy action, the loss of life is extraordinarily small. The danger in soundly-built well-equipped airships flown by competent personnel is so small that in my opinion it will come to be regarded as nothing more than an every-day risk.

In the case of sea-going ships during the last hundred years, the safety has been very greatly increased, due mainly to the increase in size and the use of more powerful propelling machinery, enabling the modern ship to meet the worst storms without much fear of foundering or of being driven on to a lee shore. The same improvements are to be expected in airships, and the larger airships of the future, fitted with more powerful and reliable machinery, will necessarily be still safer than the airship of to-day.

Modern airships have proved themselves capable of flying through practically any type of weather. There is no doubt, however, as already stated, that at present the most violent types of electrical storms are an undoubted danger to all forms of aircraft.

Fortunately, however, although the wind speed in the centre of these disturbances has

been known to reach as much as 300 miles an hour, the actual speed of such a storm over the ground seldom exceeds 50 miles per hour, and with ordinary navigation there is no reason why airships should blunder into the centres of such storms. At the worst, the danger from violent electrical storms appears to be less than the danger of rocky coasts and shallows to the sea-going ship.

Another important factor in the safety of airships is that all minor engine repairs can be carried out whilst flying. Also, owing to the number of separate machinery units, serious engine failure is reduced to a minimum.

Fog does not constitute a real danger to airships. With present methods of navigation it is not necessary to see the ground in order to navigate accurately between bases. The bases, however, should be situated in localities comparatively free from fog, to prevent delay in landing.

Regularity.—If transport by air is to possess anything more than a very limited future, it must be possible to know beforehand when the machine is going to leave and approximately when it is going to reach its destination. Regularity in this direction is essential. The chief cause of irregularity for airships up to the present has been wind, the main difficulty being the handling of ships on the ground, and the impossibility of taking them in and out of their sheds in a cross wind of much over 20 miles per hour. This difficulty has now been solved by the development of the mooring mast. With the mooring mast it will be possible for airships to embark and disembark passengers and freight with sufficient ease to meet practical requirements. It will be realised, however, that the selection of the site for all landing bases should always be largely influenced by the local weather conditions, which are not always favourable at the great centres of population.

Irregularity in length of passage due to adverse winds encountered during flight is now the more serious problem. Bad weather is usually confined to small areas, and, for this reason, much greater difficulty will be experienced in maintaining regularity over short routes. For the long routes, however, the various weather disturbances will tend to even themselves out, and no insuperable difficulties are anticipated in achieving regularity over correctly chosen routes. An example of regularity obtained even over a short route is afforded by the German airship "Bodensee," which recently carried out sixty flights between Friedrichshafen and Berlin in 64 days, although she was a new and comparatively untried type of airship.

Carrying Capacity.—I think the carrying capacity of rigid airships can be best illustrated by the accompanying Table:—

	Bodensee (German).	*R 34* (in commission).	*R 38* (under construction).	*R X.*
Length (in feet)	590	639' 5"	695	740
Capacity (in c.f.)	700,000	2,000,000	2,700,000	4,000,000
Tonnage	21·3	60·7	82·0	121·5
Maximum Speed (in m.p.h.)	80	58	70	80
Economic Cruising Speed (in m.p.h.)	60	50	60	60
**Freight Carried* (in tons)—				
For 1,000 miles	·28	9·38 (65)	23·26 (160)	34·64 (240)
" 2,000 "	—	5·26 (37)	15·00 (105)	22·28 (155)
" 3,000 "	—	1·14 (8)	6·78 (47)	10·0 (70)

* The figures in brackets show the equivalent number of passengers which should be carried, assuming 7 passengers to the ton.

A good idea of the passenger carrying capacity of airships may be obtained from this Table. The numbers of passengers given are of course only approximate, and will be limited by the amount of accommodation which could be provided. A maximum of about 100 to 120 passengers is considered quite feasible, the balance of the freight being carried in mails, parcels, and high-grade merchandise.

The following Table shows the increase in performance between a 2,000,000 and 10,000,000 cubic feet capacity rigid, allowing only for the increase in performance due to increase in size.

A still further marked increase in performance can, however, be confidently predicted due to improvements in design and to slightly more economical structure which will be practical in the larger ships.

PERFORMANCE TABLE.

		Rigid of 2 million c.f. capacity.	Rigid of 10 million c.f. capacity.
Length		645 feet	1,100 feet
Diameter		79·5 feet	135·5 feet
Gross lift (at 68 lb./1,000 cubic feet)		60·7 tons	303·6 tons
Disposable lift (60 per cent. gross lift)		36·4 tons	182·2 tons
Crew, ballast, food, etc. (15 per cent. gross lift)		9·1 tons	45·5 tons
Dischargeable lift (45 per cent. gross lift)		27·3 tons	136·6 tons
Maximum speed		78 m.p.h.	78 m.p.h.
70 M.P.H. (normal full speed)	Maximum range*	67·9 hours 4,750 statute miles	115·5 hours 8,000 statute miles
	H.P. developed†	1,700	5,000
45 M.P.H. (comparison speed)	Maximum range*	218 hours 9,820 statute miles	364 hours 16,400 statute miles
	H.P. developed†	530	1,580

* Fuel and oil consumption has been taken on the basis of ·53 lb. per B.H.P. hour.
† Thrust H.P. has been taken as equal to 70 per cent. of B.H.P. at full speed, and 60 per cent. at 45 m.p.h.

higher than that outside, so that if there are any leaks in the side of the car, warm air will be passing out, rather than cold air passing in. This will prevent draughts, and ensure an even and suitable temperature.

Comfort.—Comfort in aerial transport is essential if it is to have any extended future. The advantage of this speed is completely thrown away if the passenger on landing is physically or nervously exhausted, and has to recuperate before carrying out the object of his journey. In the large airships this need never be. Ample accommodation can be provided, both sitting accommodation during the day and sleeping accommodation at night.

The slides show the interior arrangement of a proposed passenger car. Special attention has been given to the importance of giving each passenger a good view, and the windows are so arranged that they can see both outwards and vertically downwards should they wish to do so.

Passengers sit facing each other with a table between them, rather like a large Pulman car. They can arrange the chairs and tables for "bridge" as they feel inclined. Sleepers will be provided in the shape of bunks which fold down and allow the passengers to sleep athwartships. My experience up to date is that one sleeps uncommonly soundly in an airship. On the first night of our journey in R 34 to America, I went to bed at 9 p.m., and slept soundly till 9 a.m. next morning.

The whole of the passenger car will be heated by steam generated from the engines.

Air will be admitted at the forward end of the car, where it will be warmed over radiators. The pressure inside the car will be maintained slightly

The car will be arranged so that it will not be necessary to restrict smoking any more than in a railway carriage, as the car will be completely isolated from any possible risk of fire from gas or petrol.

A kitchen with at least as good accommodation as any railway restaurant car will be provided, and our experience to date is that one's appetite in the air is extremely good.

One is struck by the absence of vibration and noise in a large airship, and the absence of smoke or dirt generally is a distinct asset.

Compared with transport by sea, the almost complete absence of sea-sickness is an important consideration. Being a shockingly bad sailor myself, I can sympathise with others, and I can assure you the motion such as there is in a large airship is so slow that there is no excuse whatever for sea-sickness.

Pleasures of Travelling at Low Altitudes.—I could speak to you for hours on this subject, but must necessarily cut this very short and get on with the more serious subjects in the paper. I shall never forget, however, the feelings not only of myself, but of every member of the crew of R 34 as we passed over Nova Scotia on our outward journey to New York last June. We were all feeling rather jaded, having been 59 hours on end over those weary wastes of water in the Atlantic, and the joy we felt at again passing over terra firma is difficult to describe.

And such a country we found spread out

beneath us. Huge expanses of dense forest on every side with hardly ever a sign of habitation—lakes, rivers, and here and there a tiny clearing where an enterprising settler had succeeded in penetrating. We were only 800 feet above the trees and going very slowly against a head wind, and there appeared to be no detail that we could not see. We could see the trees each settler had cut down during the previous winter neatly stacked and looking exactly like little bundles of asparagus. We could see where he got his water, the extent of his housing accommodation, and the amount of land he had cultivated. We could tell the nature of the soil. We got quite an insight into the rainfall of the country; the types of trees which did best; the bird life; depth of the lakes and so on; the natural drainage of the country stood revealed, and last, but not least, the glorious smell of those pine woods acted as a refreshing tonic and put new life into us.

I am afraid that I am not good at describing the pleasures of airship travel at low altitudes, but I hope that everyone of you will soon experience these for yourself.

Speed.—The time taken over the whole journey is the important factor, and the actual air speed is not the sole consideration, although obviously of great importance in reducing the time taken.

In considering long journeys of 1,500 to 2,000 miles, the intermediate landings for refuelling or for trans-shipment, if relays are provided, must necessarily greatly increase the time for the whole journey. Further, the question of flying throughout the night is a most important factor in the time required for the journey. Airships have a great advantage in the fact that they maintain a continuous air speed throughout the twenty-four hours, and owing to their great range have no intermediate landings. A continuous air speed of 60 miles per hour is reasonable to assume. It should also be remembered that the airship, by deviating from its course, can take advantage of favourable winds or slants, or, at the worst, the effects of unfavourable winds can thereby be very considerably reduced. It is, therefore, safe to assume that on the average this air speed will be made good over the ground. Where trade winds, monsoons, and westerly drifts can be made use of, which will be the case on many of the routes, the speed made good can and will be considerably increased.

Assuming, therefore, an air speed of 60 miles per hour, and allowing for the probable effect of wind on the various routes, our principal Dominions can be linked up independently of bases in foreign countries as follows:—

Journey.	Intermediate Landings (half-day halt allowed).	Duration of Flight.	Present Mail Transit.
England to Egypt	0	2 days	4-6 days
England to India (*viâ* Egypt)	1	4½ ,,	14 ,,
England to South Africa (*viâ* Egypt)	2	6 ,,	17-19 ,,
England to Australia (*viâ* South Africa)	3	10 ,,	25 ,,

Night flying is of the greatest importance, and it is here that airships are of special value. In fact, it may be stated that airships can be more easily and efficiently flown at night than in the daytime. If a passenger can leave after dinner, sleep comfortably on board, and reach his destination in time for breakfast next morning, where, owing to existing means of transport, it would have been necessary to spend, say, twenty-four hours in the train or boat, a great saving is achieved. Thus, one complete business day would be saved, provided always that the accommodation is sufficiently comfortable not to impair the efficiency of the passenger. The journey between London and Copenhagen is an admirable illustration of this.

Cost.—If I were to be asked suddenly to-day "Is the big airship a commercial proposition or is it not?" I should hedge a bit and say, "Now, this is rather a difficult question you've asked me!" But, having recovered from my astonishment, I should reply: "I am convinced that the big airship will be a commercial proposition, but I am not in a position to say that it actually is to-day, for the very good reason that it has not yet been proved one way or the other." Airships have not yet had an opportunity of showing what they can or cannot do commercially. Up till now they have only been used for military purposes in this country. I say advisedly "in this country," because in Germany they have been tried out very considerably for commercial purposes, and the answer they would give in that country

to the question I have so carefully shirked would, without doubt, be in the affirmative.

I will now endeavour to give you some idea of the cost of the rigid airship transport. I think you will agree with me that at the present stage of development of the airship this is a most difficult subject, as although many notable flights have been carried out by our own and German rigid airships under war conditions, yet these flights have only proved that there are great possibilities in the airship for commercial purposes, and have not produced sufficient data to enable actual running costs under commercial conditions to be stated. Considerable experience, however, has been gained during the past three years which is sufficient to warrant certain conclusions, and on the assumption that these conclusions are correct it will be possible to form some idea of the cost of this form of transport.

I propose to consider an airship of 2,750,000 cubic feet, similar in size to airship R 38, now building at Bedford in the Government airship dockyard. As I have previously pointed out, an airship of this size would be capable of carrying fifteen tons for a journey of about fifty hours' duration at a continuous air speed of 60 miles per hour. I propose to assume that this airship would fly about 2,500 hours in the year, and on an average would make good a ground speed of only 45 miles per hour (although I am personally confident that a ground speed of nearer 60 would be made good). This would make the yearly ground mileage covered about 112,500 miles. This amount of flying allows the airship to be laid up for three months in the year. From past experience it is considered that this will be considerably exceeded by airships operating on long distance routes.

The Cost of Airship Transport may be divided into: (1) the cost of the airship; (2) the cost of the base; (3) cost of operating the airship; (4) cost of running the base.

1. *The Cost of the Airship.*—The war cost of an airship of 2,750,000 cubic feet (R 38) is approximately £400,000, but this cost must not, I feel, be taken as a guide to the future cost of construction. To justify this statement I must point out in the first place that the airship industry is a comparatively new industry. Progress in design was rapid and construction was slow, so that airships were obsolete long before they were completed. Standardisation of production was, therefore, impossible. Progress in design also led to alterations and improvements during construction which, of course, meant delay and consequent increased cost. For these reasons, amongst others, airships in this country took anything between fifteen to twenty months to build, whereas in Germany, where development permitted a degree of standardisation, airships of about 2,000,000 cubic feet (R 34 size) took only three to four months to build. I therefore feel, and I am not alone in the matter, that as soon as something approaching a regular airship construction trade is established, the cost of a commercial airship similar in size to R 38 will be under £200,000. I must also add that future airships will be of more rugged and simple construction than those built in the past, with the object of attaining low first cost cheapness of maintenance, and a longer life. I therefore propose to take the cost of such an airship at £200,000.

2. *The Cost of the Base.*—A commercial airship base will consist of housing sheds, gas plant, workshops (situated in the annexes to the sheds) for fabric workers, carpenters, engineers, and allied trades. Landing rights over surrounding ground will be required, the extent of which will depend on local conditions. (I should mention here that any ground reasonably flat, the quality of the surface not being important, is suitable for landing.)

The cost of establishing such a base with a shed to house two 2,750,000 cubic feet airships, with all necessary equipment and plant, including a fair margin for such services as drainage, water supply, roads, but excluding cost of land, accommodation for station personnel or hotel for passengers, would be about £550,000 on present-day prices. I may point out in passing that housing sheds can easily be lengthened to meet development, provided they can be built sufficiently high and wide in the first instance.

A similar base, but with shed to house one ship, would cost £400,000.

An additional £25,000 would be required to erect and equip one mooring mast at a base.

A mooring station would consist of a mooring mast complete, gas plant, and small office and store accommodation. The size of the gas plant would depend on the amount the base is used, but a base with gas plant to produce sufficient gas for, say, two airships calling once a week, would cost about £45,000 on present prices.

The cost of the bases may appear high. It must be remembered, however, that only about five bases will be required to allow services to be run to all parts of the Empire. Bases will gradually be increased in size, and extra sheds will become necessary for repair purposes as traffic increases.

An argument invariably produced against airships is the prohibitive cost of their bases. It is interesting, therefore, to take a wide glimpse into the future. Let us make, for example, a liberal estimate of the possible future airship requirements of the Empire, and assume that this is completely met by a fleet of, say, 120 airships. This enormous fleet, with the aid of mooring masts, could be efficiently operated from five bases mentioned above, allowing for six sheds at each base. The capital outlay involved for these bases and attendant mooring stations would be something in the neighbourhood of £10,000,000.

To get the right prospective one must compare this capital outlay to the hundreds of millions laid out in permanent ways for railways, and to the enormous sums expended in docks and harbours for shipping.

3. *Cost of Operating the Airship.* — This may be divided into: (1) maintenance; (2) depreciation; (3) crew; (4) gas; (5) fuel.

Before any idea of cost of maintenance and depreciation can be obtained, it is necessary to state the probable life of an airship and its part. For this purpose the airship may be divided into: (1) fabric; (2) engines; (3) hull. With regard to fabric this may be sub-divided into: (*a*) outer cover; (*b*) gas-bags. Present experience enables the life of the outer cover to be placed at one year (2,500 hours flying), and that of the gasbags at two and a half years.

With regard to engines, owing to the fact that airship engines are not run at their full power, except in emergencies, the life can be placed at 2,500 hours, or one year.

With regard to the hull, the opinion of those best qualified to judge, places the life at not less than five years. Tests of the duralumin of No. 9 rigid after three years' use showed no weakening power. The life of the hull I therefore propose to take as five years.

1. *Maintenance.*—Under this heading are included the necessary repairs and overhauls to the fabric, engines, and hull, and replacement of fabric and engines during the life of the airship. The sum required under this heading is estimated at £40,000 per annum, or 20 per cent. of the first cost (£200,000), and this sum will be included in the operating costs.

2. *Depreciation.*—Assuming a five years' life for the whole airship, a sum of £40,000 per annum will be required, which will enable the airship to be replaced at the end of its estimated life (five years), and this sum will be included in operating costs.

3. *Crew.*—Allowing salaries slightly in excess of those now paid for equivalent work on service airships, the yearly cost of the crew would be £9,000.

4. *Gas.*—From experience during the war with present day methods of producing gas, assuming that the plant would be kept reasonably fully employed, the cost should not exceed 15*s*. per 1,000 cubic feet, which would be a net cost including maintenance and depreciation charges on the plant. The consumption of gas, assuming 2,500 hours (112,500 miles) flying per year, may be taken as 16,000,000 cubic feet, which would cost £12,000, or 2*s*. 2*d*. per mile made good over the ground.

5. *Fuel.* — Based on present day contract prices for petrol and oil, the cost under this heading throughout a year may be taken as 5*s*. 6*d*. per mile made good over the ground. I may mention here that R 34 in her Transatlantic flights averaged 1⅓ gallons of petrol per mile made good.

The above charges may be summarised as follows:—

(1) Airship maintenance . .	£40,000
(2) Airship depreciation . .	40,000
(3) Flying crew	9,000
(4) Gas	12,000
(5) Petrol and oil	30,937
	£131,937

or, on the yearly flying basis assumed, this would amount to 23*s*. 5*d*. per mile.

6. *Cost of Running the Base.*—A description of a base has already been given, but the cost of running such a base must now be considered. One hundred and twenty skilled men would be sufficient to run the gas plant and do all repairs to visiting airships; a further 50 unskilled workmen would be required for rough work. Allowing £5 per skilled and £3 per unskilled man per week, this would amount to a yearly charge of £39,000. I propose to allow a round sum of £12,000 for overhead charges (for such items as salaries, office expenses, etc.). Thus, the yearly cost of this base would be £51,000. Of the 170 men whose wages are included in this figure, I estimate 90 would be available for

landing parties. However, until landing to a mooring mast is in general use, this number would not be sufficient, and I must therefore allow for a further 200 unskilled labour for this purpose. Although this labour might in certain places be engaged as required, I propose to base my costs on the assumption that they must be permanently employed. Assuming they are also paid £3 per week, this would mean a further yearly expenditure of £31,200, bringing the total yearly expenditure to, say, £82,200.

I do not wish to enter into a discussion on the very important question of the ownership of bases, and I therefore propose, for the purpose of this paper, to assume for example that the Governments concerned would erect these bases and lease to a company for a yearly rental of six per cent. of the cost of erection. I would like to add here that the rental suggested should be more than sufficient to cover depreciation, maintenance, and repair charges. In my opinion, these bases would be national assets, and a large cash return on the cost of erection could no more be expected from such an outlay than from money spent in harbour works, such as breakwaters, channel dredging, etc.

The total yearly cost of the base, including the rental suggested above, will therefore amount to £116,700.

A mooring station, such as has been described, would require about twenty skilled men, which would include gas workers, engineers, drivers, clerks, etc. A further ten (unskilled labour) would also be required. Allowing a wage of £5 and £3 respectively, this would entail a yearly cost of £6,760, to which must be added depreciation, maintenance, and overhead charges. I propose to allow a total of £12,000 for the running of this station.

The yearly charges of bases and mooring stations on these assumptions may be tabulated as follows:—

	Double shed base. £	Mooring station. £
Rental (6 per cent. on £575,000)	34,500	5,240
Overhead charges	12,000	—
Personnel (permanent) . . .	39,000	6,760
Landing personnel	31,200	—
	116,700	12,000

Cost per ton-mile.—I have now outlined the probable "all in" costs for a complete airship service. To reduce the cost of running the base to cost per mile, operations on an actual route must be considered. I do not want to take some case which is only capable of fulfilment in the distant future. As I have already stated, airships in the future will undoubtedly only use their sheds for repairs, and in this way the percentage which each ship must bear of the terminal costs will be considerably reduced. I propose to assume that each ship operating will have its own shed accommodation, and I will therefore consider the case in which there are two bases, each with one double shed, also one mooring station, and that airships actually under construction (R 38 type) are employed.

I must mention that in order not to complicate my conclusions, I have assumed that one company is running both airships and bases.

I have allowed a sum for working capital, but I have not shown any charge for, may I call it, head office expenses, advertising, etc., but on the other hand, neither have I allowed for any revenue from special charters, advertisements, and many other ways in which a commercial airship company would earn additional revenue.

The route I propose to take is England—Cairo—India. I am assuming the two stages of the journey will each take fifty hours. I also allow a half-day stop at Cairo. England and Cairo would each have a double shed, and India would have a mooring-out base, which I have shown at Karachi. The four airships would each fly 2,500 hours per year, which it will be remembered, allows for a three-months' lay up for each ship every year. This would permit of a weekly service being run each way from England to India.

The cost of the service on the assumptions taken is as follows:—

Capital Expenditure—

	£
Cost of four airships, at £200,000 each	800,000
Cost of mooring station at Karachi	45,000
Working capital	200,000
	1,045,000
Interest on Capital Expenditure and Reserve Fund (15 per cent.)	156,750
or, say	157,000

which is equivalent to 7*s.* per mile flown over the ground.

I have neglected the whole question of insurance, as it is impossible at present to include a reliable estimate of the probable rate.

Cost of operating the airships, as previously stated, 23*s.* 5*d.* per mile flown over the ground.

Cost of running the bases per annum—

	£
English base	116,700
Cairo base	116,700
Mooring station, Karachi .	12,000
	245,400

which is equivalent to 11*s.* per mile made good over the ground.

Tabulating these costs I arrive at the following:—

Interest on capital expenditure . .	7*s.* per mile made good.
Cost of operating the airships . .	23*s.* 5*d.* ,, ,, ,,
Cost of running the bases	11*s.* ,, ,, ,,

or, an "all in" cost of 41*s.* 5*d.* per mile made good over the ground.

As I have already stated, each of these four airships would carry, as a conservative figure, 15 tons of commercial load, for a journey occupying 50 hours, which would make the "all-in" cost per ton-mile, 2*s.* 9½*d.* for such a journey.

Allowing seven passengers to the ton, which for practical purposes amounts to each passenger being allowed 1 cwt. of luggage free, and 1 ton of mails at 6*d.* per oz. for each stage of 50 hours, the following table is of interest:—

airship flying has been highly tested in Germany with successful results, and over the routes shown on the chart, with the assistance of the mooring mast, I have every reason to believe that regular services will be maintained.

Finally, as regards cost, my estimates have been based on a British airship actually under construction, and also on what I consider to be conservative assumptions.

Progress in airship performance has been most marked during the last few years, and each successive class shows great improvement over its predecessor. I feel, therefore, I am fully justified in assuming a further increase in performance in the 4,000,000 cubic feet airship, such as could be designed having regard to the many improvements which would be incorporated both from the point of view of better performance and cheaper construction. The reason I did not base my estimates on this class of ship was that she is not being built, although she could be constructed and housed in existing sheds. If, however, a cost per ton-mile is worked out for such a ship, making reasonable

England to	Airship.			Steamer.
	Approximate Time of Transit.	Mails (1 ton carried).	Passengers.	Approximate 1st Class steamer passenger fare.
Egypt	2 days	6*d.* oz.	£50	£45 to £50
India	4½ ,,	1/- ,,	100	£65 to £70
South Africa	6 ,,	1/3 ,,	120	£70
Australia	9½ ,,	2/- ,,	190	£115 to £128

The above figures are based on airships actually under construction (R 38 class), showing a profit of 15 per cent., and are based on the carriage of 75 per cent. of the possible passengers.

Conclusion.

In conclusion, it may now be fairly stated that the airship itself can be regarded as having successfully emerged from the experimental stage, but we have yet to prove the airship to be of commercial value. To prove it we must try it. I think you will agree with me there are good prospects of success.

The criticisms invariably levelled against the airship are slow speed, irregularity, and high cost. I hope I have clearly answered these three criticisms.

With regard to speed, it has been shown that over long distance routes such as I have mentioned, the airship, far from being slow, sufficiently reduces the present time of transit to alter entirely our accepted views of distance.

Then, as regards regularity, commercial allowance for operational improvements, every material reduction from the 2*s.* 9*d.* per ton-mile previously quoted, will result. I estimate the "all in" costs of such an airship at 1*s.* 9*d.* per ton-mile.

It is common knowledge that one of our chief national assets of to-day is our mercantile fleet, and I feel sure that a British commercial airship fleet of the future will be of similar value. It will assist in maintaining the security of the Empire, and will also provide the means of bringing our scattered Dominions in closer touch with the Mother Country.

[During the reading of the paper, Lord Londonderry was called away to the House of Lords, and the Chair was taken for the remainder of the meeting by Major-General Sir Frederick Sykes, K.C.B., G.B.E., C.M.G., Controller-General of Civil Aviation.]

DISCUSSION.

The Chairman (Sir Frederick Sykes), in opening the discussion, congratulated the author on his most interesting paper and on the wonderful

photographs he had shown. With regard to the question of mooring masts *versus* sheds, the author said that some people were rather pessimistic in regard to expenditure on sheds, and perhaps he was one of those to whom the author referred. It was true that he thought the big sheds which were at present necessary were a handicap upon airship development under the present financial conditions, but the author said that the mooring mast was gradually easing the pressure with regard to sheds, and there, he thought, lay a tremendous possibility of help for the future of airships. It was before the war that a mooring mast was first tried at Farnborough, when No 1 Squadron, Military Wing, Flying Corps, was there. The author then had to conduct experiments with the little airships made at that time, and as far as he remembered, although useful results were gained from those experiments, the noses came away from one or two of the ships on the masts. Much progress has been made since that time, and he was quite certain that the mooring mast would be of great value, but he thought further mechanical developments should be aimed at in regard to airship sheds. If the airship of the future was to be put upon a commercial basis, mechanical means must be devised to save the somewhat large ground *personnel* that was at present necessary to manœuvre ships into the sheds when the wind was at an awkward angle for doing so. The Germans had made developments in that respect to a certain extent, but even they, after a great deal of work, still found vast difficulties in regard to the matter. He thought, however, that it was a proposition which the inventive genius in this country could overcome if it was called upon to do so. He fully agreed with the points that the author raised in regard to the necessity for commercial airships. In the same way that the Mercantile Marine provided a reserve for the Navy, civil aviation would assure a reserve to Service aviation. Airships had made a great advance, but he thought there was still a great deal of experimental work to be done, and he felt it was on a commercial basis that airships could be used both to assist the experimental side of the Service, and also to develop the airship on its proper transport lines.

Major-General Sir William S. Brancker, K.C.B., A.F.C., said he was rather sorry that the author had not mentioned the heavier-than-air side of aviation, because his neglect to refer to it might encourage the idea that heavier-than-air aviation and lighter-than-air aviation were serious rivals. Personally he was convinced that was not so, but that they were essentially supplementary the one to the other. As the author had shown, the airship was eminently suitable for long-distance journeys over wide expanses of sea or deserts or undeveloped country, whilst the aeroplane, which was capable of considerably higher speed, was essentially a short-distance vehicle which he thought would be the collector and distributor for the big airship services when they were started. The airship and aeroplane had very much in common, in that at the present moment those interested in the development of either could prove that it must be a paying concern in the future. At the same time it must be realised that there were two serious enemies to be faced by both; first the weather, and, secondly, the question of finance, which was an extraordinarily difficult matter at present.

Sir Alan Garrett Anderson, K.B.E., said the paper was an extraordinarily interesting one, written by an admitted enthusiast, and the evidence the author had given must be discounted in the light of that knowledge. He believed, however, that all the author had said about the possibility of navigating airships was true. He did not think there was any inherent impossibility in their navigation, or that there would ultimately be found to be any impossibility in making them pay. He agreed with General Brancker that they did not compete in the least with the heavier-than-air machines. The voyager in an airship obtained a feeling of complete security —one did not notice any motion at all; moreover, there was one peculiarity that the author did not mention, namely, that there ceased to be any wind, because the airship was one with the wind. When travelling at fifty knots there was always a steady fifty-knot breeze; one did not pass from a calm to a storm and so on. He thought the chief drawback to travel by air would be the monotony that would be experienced when going long distances at a high altitude. Airships had now passed through one experimental stage, but further experiments were necessary before the public could be asked to subscribe money on a commercial basis. They would want to know more, for instance, about the figures the author gave with regard to depreciation; he himself said in the paper that progress had been so rapid that a ship became obsolete before it was built, and that, of course, upset any calculation of costs. Millions of pounds had been spent to bring airships up to their present state of development, and there was an immense amount of material available, and he therefore thought that in the national interest the Government should carry out further investigations, either themselves or through other people. In a very few months it would be possible to learn whether electrical storms could be avoided, how long the engines would run, and all the other things that a commercial man wanted to know in order to see if he could make the airship pay. As soon as it was understood how to make it pay, someone would go to the Government and say: "For so much a year I will relieve you of the whole cost of maintaining your airship fleet, and you shall have these commercial ships in time of war," and very soon after that they would simply pay in the ordinary way. He did not think the cost of the bases or the expense of each ship need frighten anyone. The cost of £500,000 for a base, or, say,

£2,000,000 for equipping a long route with bases, was not so much as the cost of one big liner. Ocean ships required lightships, lighthouses, dredging channels, etc. Until it was known, however, that airships would be able to run regularly, which was the essential thing, people could not be asked to subscribe. The Government should go ahead at once. The most expensive thing they could do at the present time was to dawdle, and in regard to airships, as in many other enterprises, courage and economy went hand in hand.

Major G. Hurlstone Hardy said that, contrasting the prospects of commercial aviation with the transport of the present day, shipping and railway carriage, he was not convinced by the optimistic ideas that had been put forward. There were two difficulties with regard to airships to which he wished to refer. One was the impossibility of locating where an airship happened to be when under adverse and comparatively unknown control by the wind. When sight was lost the navigating power of the compass was reduced to a minimum. One only knew the direction in which the helm had kept the ship going, and a side wind might take it miles away. That had been proved in the case of the three aeroplanes that set out from North Wales for Dublin and were never heard of again. It was conjectured that they got into a cloud fog so that they could not see the sea or the land, and that they drifted south of Cork and out into the Atlantic. Another case in point was that of the last German airship attack on London, when of the large number that arrived in England some three were brought down, others landed in most distant places, and some were never heard of again. He did not feel at all satisfied that navigation could be carried out in a cloud fog. The other point, to which he wished to refer, was the author's estimated cost of 2*s.* 9*d.* per ton-mile. The reconstruction of the country demanded more extensive commerce than had ever been known before; transport for the necessities of life was required in much larger bulk than ever before, and it ought to be in pence and not in shillings per ton mile. When one considered the outlay necessary on landing stages and all the other things connected with airships it would be seen that the expenditure when contrasted with other forms of transport was very great — it was just the difference between a commerce of luxury and a commerce of democratic necessity. Ships had, with feasible repair, a useful lifetime of sixty years or more; railway engines and rolling stock served for, say, thirty years, and road vehicles for a little more or less. But the lifetime endurance of aeroplanes and airships should be reckoned respectively in weeks and months rather than in years, inasmuch as repairs engendering safety in such frail craft were not feasible in any way comparable to those ordinarily carried out in structures built on more solid designs. Counting cost against cost in connection with volume of traffic, the figures would work out enormously in favour of naval commerce and intercourse. He agreed as to the prospects of aviation for exploration and for other special purposes, but there were such severe limitations on its commercial prospects as would discountenance remunerative expectation.

Commander E. S. Land, C.C. (U.S.N.), wished to congratulate the author on his fascinating paper, which rather brought to one's mind Jules Verne's "Twenty Thousand Leagues under the Sea" and Kipling's "Night Mail." The things described in those books had now been materialised in the submarine and the airship. In America there was a certain class of man sometimes called a "promoter," the kind of man who would furnish the ocean if someone else provided the ships. The author was prepared to furnish the airships and it appeared that the British and American Governments were prepared to furnish the air. Pioneers in any line must expect to run up against rocks, and that was what the pioneers of aviation were doing at the present time. One point in which he was particularly interested was interchangeability of commercial and military airships. He thought it was easier to convert a military airship into a commercial airship, and *vice versâ*, than it was to convert an old-time sailing ship into a man-of-war. Two matters had to be considered in that connection: first, material; and, secondly, *personnel.* With reference to the question of mooring masts *versus* sheds, he understood the Germans still adhered to the rotary shed proposition. He did not think commercial aviation could make proper progress without Government help. The Government had helped in every transportation scheme that had ever existed. The best rail-road system in the United States was not built by private capital alone, but was assisted by Government capital. The general attitude towards the subject seemed to be one of indecision, and if a decision was not speedily arrived at our late enemies would leave us "asleep at the switch."

Colonel E. Gold said he did not think from the point of view of the mechanics of the atmosphere there was a great deal of danger to the airship of the future, but it was quite certain that there would be many occasions in an airship service between India and England when an airship arriving in this country would not be able to reach a definite fixed place, such as Pulham. That difficulty could be overcome by having mooring masts not only at Pulham, but also along the route across the Continent; then aeroplanes could come and take the passengers for the rest of the distance and not keep them waiting for the wind to fall at Pulham. With regard to the equatorial region, he was not quite clear that the electrical difficulty, that was to say, the difficulty of discharge inside the airship or through the covering of the gas holders, had been met. Probably, by careful observations, even without an elaborate system of warning, an airship

would be able to avoid the centre of tropical revolving storms, but it could not avoid getting into regions where there were very great variations in the electric potential, and that might produce discharges from the ship. There was one meteorological point on which the author did not lay stress, and that was the advantage an airship would have in being able to avoid very high temperatures when travelling through equatorial regions. An airship travelling from this country to India could do so in temperatures not exceeding 80° F., and the passengers would never be subjected to those discomforts which arose from being shut up in a cabin with a temperature of 110° F. A great deal could be done in airship transport by utilising what was already known about the general wind, and also by utilising the winds in different layers in the equatorial regions. Roughly speaking, if the wind was west it would be a west wind all the way up, but if it was an easterly wind it would normally change into a westerly wind up above. In the extensive regions near the Equator, where there were easterly winds down below, there would usually be westerly winds up above, or at any rate the easterly winds would decrease. The airship would be able to take advantage of that, and so utilise the energy of the sun translated into motion in the atmosphere. The existence of mankind depended on the energy it obtained from the sun, and at the present time the energy obtained direct from the sun should be used in every practicable way, and the stored-up energy of the sun, such as in coal, should be kept as long as possible for use where the direct energy could not be employed. Airships provided an opportunity of doing that by making use of the wind, thus making an economical use of the energy that was being received in such vast quantities day by day from the sun.

Wing Commander T. R. Cave-Browne-Cave, C.B.E., said the paper had been particularly interesting to him, because, although he was fairly well acquainted with what had been done in regard to Service airships up to the present time, he had had nothing to do with deducing from those data what could be done with airships in a commercial way. The author stated very clearly the data on which his calculations were based, the deductions from those data were then arrived at by a method which was stated, and thus definite conclusions were obtained. If one agreed with the data and could not find any flaw in the method of deduction, one must accept the conclusions. That was his position with regard to the paper, although the results obtained, such as those shown in the tables, were probably distinctly surprising to the majority of those present. With regard to the question of whether the airship was still in an experimental state, he thought that, although there was still an enormous amount of experimental work to be done, it must be realised that sufficient was now known about airships and the difficulties they experienced to be able to tell along what lines research was required. The amount of *wasted* experimental effort should in future be very small indeed. One rather remarkable figure given in the paper was the cost of the airship. The cost of an airship such as the R 38 was about £400,000, but the author suggested that the cost of a similar airship in the future would be about £200,000. That seemed a very considerable reduction, but he thought it was a reasonable one. In the construction of airships by the present methods a very large proportion of the cost was allocated to labour. The present methods of construction were so extremely primitive compared with what they would be in the future that experience in construction was bound to lead to enormous economies. For instance, the gas-bag of a ship was now covered by hand with gold-beater skins, each covering a space of only about 5 in. by 10 in. or 12 in., and that would be done by machinery in the future, which would mean a considerable reduction in cost. With regard to the difficulty that had been mentioned of finding out one's position when in an airship, that was done quite irrespective of one's dead reckoning. One method was by directional wireless and the other by taking sights as employed in the Navy. The case that had been quoted of the three aeroplanes that set out to go to Dublin was not entirely to the point, because, if those machines had any means of determining their position at all, which he thought was very doubtful, they had very difficult conditions in which to use them. Those conditions did not apply in an airship. One could determine one's position far more easily in an airship than in a destroyer or in many merchant craft. The airship had the advantage that it was able to go to what altitude it liked in order to get a clear horizon, whereas a destroyer or other surface ship which got into a fog might have to slow down for that reason. With regard to the question of danger from lightning, he might quote from the trials of R 24 when moored to a mast. In that case the airship was connected to earth through the mooring mast, down which there was a water main. Whilst there a thunder-storm of quite exceptional violence passed right over the station. The lightning in the neighbourhood of the ship was so intense that although there was no other illumination in the ship it was possible to read instruments clearly at night. Considering that the thunder-storm was quite exceptional in its violence, and that the airship was connected to earth and yet was not affected by the lightning, he thought the system adopted at present of bonding together all the various metallic parts of the ship must be regarded as satisfactory. The figure of cost given in the paper had been worked out generally in the same manner as had been done for heavier-than-air propositions, and he thought it would be extremely interesting to compare in detail the basis on which the author's costs had been worked out with the basis on which figures had been

worked out for the corresponding heavier-than-air suggestions.

Mr. H. White Smith said a great deal had already been done in regard to airships under military conditions, and it was now necessary to know more about them from a commercial point of view. It was to be hoped that, either with Government assistance or by private enterprise, something might be done to institute what might be called an experimental line of commercial airships, possibly from this country to Egypt, which was a route that seemed very suitable for such a project. There were airship sheds in this country and also, he believed, in Egypt. Such an experimental route would furnish data on which to judge whether commercial airships could be run successfully. On such a route the airship had an advantage over the aeroplane because it could go the whole distance straightaway, whereas the aeroplane had to pass through France, Italy, possibly Greece and other countries, and the people operating the aircraft of those countries would want to take their part in the project, thus raising possible international difficulties. Such a route would also have an advantage in that it would link up with the proposed heavier-than-air experimental service which would be instituted from Cairo to Karachi.

Air-Commodore Maitland, in replying to General Brancker, said he did not mention aeroplanes in the paper because he was trying to confine himself entirely to the airship problem, but he quite agreed that the airship and the aeroplane must work together. They were going to be of the very greatest help the one to the other; in fact, he believed they would be quite indispensable to each other. The big airships would do the long oversea routes and a great many of the long-distance overland routes, and the aeroplanes would radiate out in every direction, both from the airship bases and also from their own bases. He quite agreed with Commander Land that the Germans would leave us behind in the matter if we did not "get a move on." The Germans were very enthusiastic about the airship and were certainly making good progress, which would be increased when they got greater opportunities for going ahead. The reason the Germans did not use mooring masts was that their weather was a great deal better than that in this country, and so they could get their airships into the sheds very much more easily than we could. In spite of that, he believed that when the usefulness of mooring masts had been demonstrated in this country the Germans would follow suit and erect them in Germany. He agreed that transport per ton mile should be in pence and not in shillings, but we must start with shillings and perhaps would be able to bring it down to pence later on.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

NUTS AND MEDICINAL PLANTS IN COLOMBIA.

In the course of a lengthy report on the economic resources of the Cartagena district, the United States Trade Commissioner at Medellin gives the following figures of the exports of forest products from Cartagena in 1918, all of which were gathered by the negroes and natives of the interior, the work extending as far as the headwaters of the Atrato River:—

Balsam copaiba	7,365	lb.
Canine oil	11,401	,,
Cedar and mahogany	1,200,639	ft.
Chicle	86,585	lb.
Ipecac	47,181	,,
Ivory nuts (tagua)	4,063,011	,,
Palm-kernel oil	65,076	,,
Rubber (balata)	395,318	,,
Sisal fibre	20,882	,,
Tannic extract	733,751	,,

Another product that deserves mention is the nut of the corozo palm. This palm is the same as the "cohune" of Central America, and is found in great abundance throughout the Bolivar plains and as far west as the Atrato River. There is an unlimited supply of raw material. When pastures are cleared for cattle the corozo palms are left for the gathering of the seeds. The gathering of the nuts presents no particular difficulty. Two harvests are obtained yearly after the palm has reached maturity, which is attained at the age of four or five years. The nuts are very rich in food value, the oil having been used by the aborigines for centuries. The extraction runs about 25 per cent. of pure oil per weight of raw nuts after drying. About 25 lb. of the nuts, which grow in large bunches near the ground, can be expected from each palm annually.

The tagua nut is one of the principal articles of export of Cartagena. The chief supply comes from the region of the Atrato River to Cartagena for export, although the Pacific coast of Colombia exports large quantities also.

The forests of Bolivar and the regions of the Sinu and Atrato Rivers, particularly the latter, are rich in medicinal plants, such as the ipecacuana, or the ipecac of commerce, sarsaparilla, cinchona bark or quinine, cascara sagrada, and many others. About £10,000 worth of these products are shipped each year from Cartagena to the United States. There are also several palms which produce gums and varnish material, such as the famous ceroxylon palm, but, so far, little or nothing has been done in this region toward the collection of these gums in marketable quantities.

COMMERCIAL USES OF MANJAK IN TRINIDAD.

Manjak is said to be more abundant in Trinidad than in any other part of the world—in fact, with the exception of Utah, Cuba, and Barbados, there are understood to be no other important known deposits. In case of a large demand arising for

manjak, Trinidad probably offers the best opportunity for its production and export as an article of commerce.

While Trinidad is rich in its resources of manjak, the mining of it is as yet only in an experimental stage, and such exports as have taken place have apparently been chiefly for the purpose of testing uses to which it may be put.

In Trinidad itself, writes the United States Consul there, manjak is very rapidly coming into increasing use. Its utilisation in connection with the oil industry is especially important, manjak being produced in close proximity to the oil wells of the island. It is boiled locally with oils at high temperatures, and made into compounds and paints for use in the oil fields for practically every purpose for which a preservative is required—for pipelines, boilers, chimneys, sprocket wheels, pinions, and other ironware, machinery, etc. Entire pipelines are painted with it, and apparently, wherever it is used, the metal, which would otherwise quickly deteriorate in the hot and damp climate, has its life almost indefinitely prolonged. When applied in a liquid state the manjak quickly and readily hardens into a tough, unbreakable, and rubberlike coating. It has a low viscosity, is not affected by ordinary heat, is a most excellent insulating material, and is impervious to both water and air.

The most important use of manjak, and the one for which it has won a reputation for immense saving of money, is in connection with rotary drilling for oil. A soft compound is used on the joints of the pipes between the casing threads and drill stem threads, and this prevents either water, sand, or grit getting into the threads, and so preserves them from being stripped or worn off. It not only acts with particular efficacy in keeping such pipes water-tight and air-tight and free from corroding influences at the joints; but also, having qualities as a lubricant, it facilitates the work of joining and separating the pipes. It has been found much superior for such purpose to white lead or any other substance previously used, and results in very great economy.

The Government of Trinidad is now making important use of manjak in painting the under parts of bridges, and in other cases where protection is required from water; and a Trinidad company has secured excellent results from the use of manjak paints and compounds on steel smokestacks, trucks, fenders, and buffers, galvanised iron cans which are submerged in brine, and iron and steel work in connection with power-house and car building. The company also uses it successfully as an insulating varnish on armatures and electrical connections, and in gear cases of mechanically-propelled vehicles. It has proved especially valuable in connection with overhead canvas-coverings for vehicles, as protection from the hot tropical sun and rain.

The manjak deposits of Trinidad are found within a distance of only about three miles from San Fernando, the second largest town of the island, and within about ten miles of the famous asphalt lake at Brighton. Manjak is much like asphalt in its chemical composition; but while the melting-point of asphalt is low (100° F.), a temperature of over 400° F. is required to melt manjak. It is almost a pure bitumen. It looks like coal, is odourless, and is very hard and brittle, having a pencillated structure easy to separate in its long grains. It is found in long seams between layers of clay.

Manjak was mined in a small way in Trinidad previous to the year 1900, until a serious accident occurred from explosion of gas, resulting in large loss of life and so discouraging the proprietors that mining operations were discontinued. In 1913, however, mining operations were resumed by a company, which, by making use of modern safety appliances—especially safety lamps—has averted any further accidents. There are now five shafts, one of which reaches a 37-foot seam at a 400-foot level. The area where the mining operations occur comprises about 1,600 acres, one-half mile from the Gulf of Paria. The operations could be greatly extended should the business conditions warrant it.

It has not been found profitable to export manjak from Trinidad in its crude state, the price received of only about thirty-five dollars per ton hardly covering the cost of mining—an expense which is increased by the necessity of thoroughly timbering every tunnel and opening because of the loose formation of clay. However, by compounding the manjak with mineral oil, the special preparations thus made have been found to command very good local prices, and to make the mining operations quite profitable so far as they go. There is still considerable experimentation with different mixtures and different kinds and weights of oil for specific purposes, and the manjak which has lately been exported to the United States has been sent there for the purpose of testing whether American oils would prove more economical and useful for mixing purposes than Trinidad oils. It is the intention shortly, adds the American Consul, to erect a plant, either in the United States or in Trinidad, for the manufacture of a variety of manjak paints and compounds for all the special purposes for which they may be required.

THE CHUQUICARA RAILWAY OF PERU.

Work was commenced in July of last year on the construction of the Chuquicara Railway, a branch of the Chimbote Railway, which, leaving this line at 75 kilometres, will run in a northerly direction up the valley of the Chuquicara River, with its immediate objective, the Ancos coalfields, 25 kilometres (15½ miles) distant. Ultimately, the line will pass within about 30 kilometres of the Magistral copper district, through the town of Santiago de Chuco, within 10 kilometres of the Chimborazo copper deposits, and through the towns of Huamachuco and Cajabamba. This region and that lying still further to the northward is one of the richest mineralised sections of Peru.

The contractors for the construction of the section from Chuquicara to Ancos expect to complete the work by the beginning of 1921. According to a report by the United States Vice-Consul at Callao-Lima, the Chuquicara Railway is typically a mountain railway. There are four tunnels in the first 10 kilometres, and 27 retaining walls in one 3-kilometre section. One section of 4 kilometres is said to equal the most difficult section of the Central Railway, and preliminary work is being carried on with men suspended from ropes over the mountain walls.

The abutments of the bridge to be built over the Santa River at Chuquicara have been completed. The bridge will have a length of 131 ft. Like the Chimbote Railway the gauge of the Chuquicara branch is 91 centimetres, but the permanent way is being adapted to normal gauge in the event of it becoming desirable to alter the gauge in the future.

The financing of this extension is being carried on by the Government with a portion of the revenue from the tobacco monopoly. The entire revenue of this monopoly was allocated to railway construction by the railway law passed in 1918.

The Ancos coal deposits which will be reached by the Chuquicara extension are semi-anthracite, averaging roughly 78 per cent. in fixed carbon, 14 per cent. volatile matter, and 8 per cent. ashes. It is used in place of coke by some of the mines in this region, though coke is of course preferable. All of the coal claims in the Ancos deposit have already been taken up.

GENERAL NOTES.

JAPAN AND THE RESTRICTION OF ARMAMENTS.—In a recent issue of the *Proceedings* of the United States Naval Institute there are printed translations of a number of articles which have appeared in the Japanese press on the subject of that country's "eight-and-eight" naval building programme, and discussing her position—for, as a member of the League of Nations, Japan has signed the covenant recognising the necessity for the reduction of armaments. The Tokio *Jiji*, a pro-Government organ, states that Japan's naval programme is not new but dates back to a time shortly after the termination of the Russo-Japanese war. At that period, the scheme known as the "eight-and-eight" fleet (eight battleships and eight battle-cruisers) was generally recognised by specialists to be the minimum limit of Japan's naval equipment, and if it had not been for financial or political obstacles the plan would have been completely carried into execution several years ago. Accordingly, it is thought that Japan can increase the "eight-and-six" fleet (actually in process of making) into an "eight-and-eight" fleet without provoking the suspicions of other Powers. The opinion of the Japanese Navy Department in regard to the question of the limitation of armaments seems to be as follows: It is understood by every Power that Japan has a special position in the Far East, and is charged with the responsibility of preserving the peace of the Orient. Secondly, Japan is justified in aiming at an "eight-and-eight" standard because during the war all European nations extended their armaments, but Japan was not able to achieve even the pre-war minimum—therefore it is impossible for her to reduce her programme. Japan has no aggressive purpose, but the "eight-and-eight" programme is a minimum for meeting her responsibilities in the Far East and ensuring her self-defence.

THE FOUNDATION OF AN INSTITUTE OF PHYSICS.—The need has long been felt for a corporate body, analogous to the Institute of Chemistry, which would represent the profession and strengthen the position of workers engaged in physics, and which would also form a bond between the various societies interested. At present the physicist is hardly recognised as a member of one of the professions, but the vital importance of many developments of physics during the war and the certainty of its growing importance, both in science and industry, are bringing about a change in this respect. It is one of the aims of the new Institute of Physics to secure recognition of the position and value of the physicist, and it is felt that such recognition can only be obtained by the co-operative action of all the physicists in the country. The Institute has been founded by the co-operation in the first instance of The Faraday Society, The Optical Society, and The Physical Society of London, and the first Board is constituted from representatives appointed by the Councils of these Societies. It is hoped that in the course of time other Societies will associate themselves with the Institute. Members of the Institute who are also members of more than one of the co-operating Societies will obtain a reduction to the subscription to those Societies. There will be three classes of members: Ordinary Members, Associates (A.Inst.P.), and Fellows (F.Inst.P.). Only the two latter classes, membership of which will require full professional qualifications, will be Corporate Members. The Institute has already received promises of support from leading physicists, and the initial expenses are covered by a Guarantee Fund amounting to over £1,200. The first President of the Institute is Sir Richard Glazebrook, K.C.B., F.R.S., Sir Robert Hadfield, Bart., F.R.S., is Treasurer, and Professor A. W. Porter, F.R.S., Honorary Secretary. The other members of the Board are: Dr. H. S. Allen, Inst. Commander T. Y. Baker, R.N., Prof. F. J. Cheshire, C.B.E., Dr. R. S. Clay, Mr. W. R. Cooper, Prof. W. H. Eccles, Major E. O. Henricé, Dr. C. H. Lees, F.R.S., Mr. C. C. Paterson, O.B.E., Major C. E. S. Phillips, Dr. E. H. Rayner, Mr. T. Smith, and Mr. R. S. Whipple. Mr. F. S. Spiers has been appointed Secretary to the Institute, and further particulars and Forms of Application for Membership may be obtained from him at 10, Essex Street, Strand, W.C. 2.

Belgian Railways.—At the beginning of last year, according to the *Railway Gazette*, the total number of Belgian locomotives actually fit for service only amounted to 279. By the end of 1919 this number had risen to 2,700. The effect of this increase was to make it possible to operate 50 per cent. of the pre-war passenger service and 65 per cent. of the pre-war number of goods trains. In addition, 675 new locomotives were ordered last year. Altogether, 9,400 passenger vehicles and 57,800 goods wagons of various types were repaired during the year, and 9,000 new wagons were ordered. Perhaps the most striking fact in the whole of the year's working was that in December, 1919, it was possible to run some 1,100 goods trains a day, which is forty times the number operated in January of the same year.

Portable Houses for Seville.—According to the American Consul in Seville, rents have become so high that many poor people are forced to leave the city, and it is felt that the demands for higher wages would cease, or at least be reduced, if labourers could find houses at a moderate rental. As there is practically no lumber in Spain for building wooden houses, and the expense of constructing them of brick is prohibitive, it has been suggested to the civil authorities that portable houses might be imported from the United States. The city owns a large tract of land along the Guadalquivir River, and it is planned to erect houses of from two to four rooms on this property for the use of the labourers, the occupants paying rent to the city for the use of these houses. At present a thousand such houses are being considered, although more will probably be needed later.

MEETINGS OF THE SOCIETY.

Indian Section.

Friday afternoon, at 4.30 p.m. :—

June 18.—Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.) The Right Hon. Lord Meston, K.C.S.I., LL.D., will preside.

Cantor Lecture.

Monday evening, June 7th, at 8 p.m. (lecture postponed from April 26th) :—

Walter Rosenhain, B.A., D.Sc., F.R.S., Superintendent, Department of Metallurgy, National Physical Laboratory, "Aluminium and its Alloys." (Lecture III.)

Syllabus.

Special Uses of aluminium alloys—Castings for automobile and aeroplane parts—Castings for aero-engines—Pistons and piston alloys—Properties at high temperatures—Automobile and aero-cylinders—Other engine parts—Structural uses—Rigid airships, aeroplane spars, and wing-coverings—Possible future developments.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 7 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. W. Rosenhain, "Aluminium and its Alloys." (Lecture III.)

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Professor Dr. G. A. F. Molengraaff, "Ocean Research in the Dutch East Indies."

Tuesday, June 8 ... Colonial Institute, Central Hall, Westminster, S.W., 8 p.m. Miss F. B. Lysnar, "New Zealand."

Wednesday, June 9 ... University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Professor A. J. Toynbee, "Egypt and Mesopotamia (Fourth Millenium to Sixth Century B.C.)."

Geological Society, Burlington House, W., 5.30 p.m. Dr. C. G. Knott, "Earthquake Waves and the Elasticity of the Earth."

Electrical Engineers, Institution of (Wireless Section), at the Institution of Mechanical Engineers, Storey's-gate, S.W., 6 p.m. Mr. M. M. Latour, "High Frequency Machines."

Thursday, June 10...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Mining Engineers, Institution of, at the Geological Society, Burlington House, W., 11 a.m. 1. Professor H. Louis, "Compensation for Subsidences." 2. Mr. W. Maurice, (*a*) "The Fleissner Singing-flame Lamp." (*b*) "The Wolf-Pokorny and Wiele Acetylene Safety-lamps." 3. Mr. G. Oldham, "The 'Oldham' Cap Type Miner's Electric Safety-lamp." 4. Discussion on papers already published: First Report of the Committee on "The Control of Atmospheric Conditions in Hot and Deep Mines." Mr. D. S. Newey, "A New Method of Working Thick Seams of Coal at Baggeridge Colliery." Mr. T. G. Beckins, (*a*) "Protractors." (*b*) "Magnetic Meridian Observations: A Method of Utilising the Kew Observatory Records."

Metals, Institute of, at the Institution of Mechanical Engineer's, Storey's-gate, S.W., 8 p.m. Professor C. A. F. Benedicks, "Recent Progress in Thermo-Electricity."

Optical Society, at the Imperial College of Science and Technology, South Kensington, S.W., 7.30 p.m. 1. Miss A. B. Dale, "Accuracy of Setting." 2. Dr. J. S. Anderson, "A New Method of Immersion Refractometry."

Historical Society, 22, Russell-square, W.C., 5 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Mr. E. L. Joseph, "Ventilation and Air Purification as applied to Modern Concrete Buildings."

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Captain A. N. J. Whymant, "Chinese Customs and Etiquette."

Friday, June 11 ... Malacological Society, at the Linnean Society, Burlington House, W., 8 p.m.

Astronomical Society, Burlington House, W., 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Journal of the Royal Society of Arts.

No. 3,525. VOL. LXVIII.

FRIDAY, JUNE 11, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

FRIDAY, JUNE 18th, at 4.30 p.m. (Indian Section.) SIR VALENTINE CHIROL, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.) The RIGHT HON. LORD MESTON, K.C.S.I., LL.D., will preside.

INDIAN AND COLONIAL SECTIONS.

FRIDAY, JUNE 4th; THE RIGHT HON. E. G. PRETYMAN, M.P., in the chair. A paper on "The Oil Resources of the British Empire," was read by PROFESSOR SIR JOHN CADMAN, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On Monday evening, June 7th, DR. WALTER ROSENHAIN, D.Sc., Superintendent of the Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, delivered the third and final lecture of his course on "Aluminium and its Alloys."

On the motion of the CHAIRMAN, Engineer Rear-Admiral SIR GEORGE GOODWIN GOODWIN, K.C.B., a vote of thanks was accorded to Dr. Rosenhain for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

EXAMINATIONS.

The results of all stages of the examinations held from March 22nd to 31st have now been sent to the centres concerned.

In the Advanced Stage 1642 papers were worked. Of these 237 were awarded first-class certificates, 656 second-class certificates, and 749 failed.

In the Intermediate Stage the number of papers worked was 5,108, with 677 first-class and 2,650 second-class certificates; the failures numbered 1,781.

In the Elementary Stage 9,496 papers were worked. The passes numbered 6,103, and the failures 3,393.

In 1921 the first, or Easter, examination will commence on Monday, March 14th, and will finish on Wednesday, March 23rd. The second, or Whitsuntide, examination will commence on Monday, May 2nd, and finish on Wednesday, May 11th. Detailed time-tables will be issued shortly.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 28th; The Right Hon. LORD DESBOROUGH, K.C.V.O., in the chair.

THE CHAIRMAN said it was his privilege to introduce the lecturer, Brigadier-General Charles H. Sherrill, who was to lecture on a most interesting subject. His inducement to take the Chair on that occasion arose more from his personal connection with Brigadier-General Sherrill than from the subject of the paper. He had had the pleasure of meeting the lecturer when he was doing very good work at the International Chambers of Commerce in Paris the year before the war; and he knew him as one who did excellent service in training some considerable portion of the huge army which eventually sailed from America. He had devoted a life-long study to the subject of stained glass, and had written at least two books on the subject, "Stained Glass Tours in France" and "Stained Glass Tours in England." He might mention that he himself had had some beautiful stained glass which had been taken out of the old manor house of Ockwells in the county of Berkshire, and he had had the privilege of giving that stained glass to be put back into the old manor house when it was restored. His joy in being able to do that was somewhat tempered later on, when a dealer told him that he would be very pleased to offer him £24,000 for the glass. It consisted largely of old

coats-of-arms, one of them being the arms of Henry VI.; and as Henry VI. was deposed somewhere about 1461, the chances were that the glass dated back even before that period. Most people were interested in stained glass, and he thought the Society was very fortunate to have someone who could speak on stained glass with so much knowledge, authority and enthusiasm as the lecturer.

The paper read was—

A STAINED-GLASS TOUR.

By Brigadier-General Charles H. Sherrill, LL.D., of New York.

It is rather as a traveller, a mere sightseer, that I should come before your honourable Society to-day, and not as one laying claim to any especial knowledge of the charming craft whose product we call "stained glass." The books I have written upon English, French, and Italian glass have been meant only as guide-books, intended to facilitate and encourage the viewing of fine old windows, not only by those already interested therein, but also by others who, finding tours laid out for them all ready to hand, might thereby be induced to see for themselves some of the beauties left to us by the window-makers of the Middle Ages. So glorious are those combinations of colour and light, that I am convinced that if only more people could be enticed to look upon them, their inherent charm would so lay hold upon these casual observers as to make them as devoted enthusiasts as I myself have become.

In that spirit let me come before you to-day, asking you to accompany me upon a stained-glass tour, which, I hope, will prove but a preliminary to more extended ones by not a few of my hearers. We will cross the Channel several times, for, alas! like true love, the course of ancient glass never did run smooth in either England or France. Italian glass began much later than the French, ripened more quickly, and ended earlier; while in Germany the craft, beginning early, developed methodically with no serious interruptions, and ended late. We will begin by looking at some twelfth and thirteenth century examples of the *peintres-verriers'* art in France, where those two periods produced so many and such fine examples of their art, whilst little or none was being made on this side of the Channel.

Those artistically fruitful years were followed in France by the dark days of the fourteenth and fifteenth centuries, when the so-called Hundred Years' War so long outlasted its title, and when the constant harrying of France by English forces, combined with plague and uprisings of peasantry, checked the output of such artistic luxuries as stained-glass windows. But, fortunately, both for us and the craft, we need only return across the Channel to find here in your island home a veritable outburst of coloured windows, lasting all through the fourteenth and fifteenth centuries, changing in expression, however, as your architecture developed through the budding and blossoming of your decorated and perpendicular styles.

By the time the sixteenth century arrived, your glass men would seem to have shot their bolt, and to have almost ceased from practising their profession, so slight is their output thereafter. The Renaissance, so vitalising a movement on the Continent, did not seem to show such a compelling revival of art initiative with you as it did with the French, which, perhaps, is but natural, for the Italian wars of Louis XII. and Francis I. had not only shown their soldiery the ancient glories of Italian art, but had also, through the trophies they brought home with them, fired the imagination of French artists in all fields of production. You lacked these military missionaries of classic art, and therefore we must once more leave England and cross the Channel to follow our studies. Again, the crossing will be rewarded by sight of a wealth of windows, but this time entirely classic and no longer Gothic in their detail and feeling. With all that France can rightly boast of its triumphs in sixteenth century Renaissance stained glass, plus a few English windows, we will end our rambles. After all, five centuries make rather a long journey for one afternoon; indeed, I can only hope your patience will endure till its close.

So markedly did the different styles of glazing alter with the changing centuries or periods, that it needs no profound student to recognise the approximate date of a mediæval window. During the sixteenth century, the French glaziers had the obliging custom of dating their work, either quite openly or else with artistic coquetry—as in the case of a window at Les Iffs, where the date is marked on a coin held by one of the figures. Heraldic blasons, so much more frequent in England than in France, are very helpful in fixing not only the time of manufacture, but sometimes even more than that, for it is the shields set out upon Gloucester Cathedral's East window that tell us that it commemorates those gallant English knights who fought at Crécy. Because the St. Edmund

window in Bristol Cathedral shows the arms of Humphrey de Bohun, Earl of Hereford, slain in open rebellion in 1322, and does not bear those of Piers Gaveston, murdered in 1312, we can safely date the glass somewhere between those occurrences, say 1320. Because in one of the towers of Knole, that delightful and stately home of old England, a morsel of glazing, high up in a tracery light, shows the double bowknot of Bishop Bourchier of Canterbury, we know that this portion of the ancient pile is at least as old as his tenancy there, which was 1456–86. Blasons are not so helpful in France, both because their heraldry was not so precise as the English, and also because an edict in 1792 caused the destruction of many of them. And this destruction was continually going on through the centuries, sometimes chargeable to misfortune alone, but frequently to deliberate act. The Huns near Rheims have not been the only vandals from whom this handicraft has suffered. Aubrey's "History of Surrey" records that during the Reformation "one Blesse was hired for half a crown a day to break the painted glass windows of Croydon." At Lincoln the citizens practised shooting with the cross-bow at the Cathedral's windows, while at Great Malvern they quite simply threw stones at them! As early as 1330, the Commune of Assisi had to impose a fine of five lire for throwing stones at their great church's windows. When Rome was besieged by the Bourbon in 1527, its numerous ancient windows were broken up to get their wealth of lead for bullets. And sometimes peace was as destructive as war, for when Charles V. was being crowned Emperor by Pope Clement VII. in Bologna Cathedral, the salvoes of artillery broke much of its old glass. At Salisbury, during Wyatt's ruthless restoration, we read that "whole cartloads of glass, lead, and other rubbish were removed from the nave and transepts and shot into the town ditch, then in course of being filled up; whilst a good deal of similar rubbish was used to level the ground near the chapter-house." It is somewhat consoling to learn that in 1632 the Recorder of Salisbury, found guilty of destroying the Creation window in St. Edmund's Church (in order, forsooth, to let in more light!), was imprisoned, fined £500, and made to apologise to the Bishop of Salisbury. After reading the boast of "Blue Dick Culmer," the Minister at Canterbury Cathedral during the Commonwealth, of his "rattling down proud Becket's glassie bones with a whole pike in his hand, when others present would not venture so high," we may be pardoned the anachronistic wish that the knights who slew Becket there had chosen Culmer instead.

Glass of the twelfth and thirteenth centuries was made up of much smaller bits than are later seen, and because this meant, to hold them in place, a labyrinth of light-obscuring lead lines, and also because even uncoloured glass was then less translucent than it is to-day, dimly lighted interiors were the natural result. The little figures that peopled the panes in those early days were collected together in groups within borders shaped like medallions, so this orderly arrangement resulted in their type being called "medallion glass." English medallions tended to be smaller than their French cousins, because Early English lancets were narrower than contemporary French embrasures. In Italy the medallions were more varied and fantastic in their shapes than in either England or France. Sometimes this glass is called mosaic, because made up, as is mosaic, of such small bits of glass. Thirteenth century glass is famous for its jewelled glitter, caused by the diminutive panes breaking up and combining the rays of light. This was not the result of chance, for in the twelfth or preceding century the pieces of glass were distinctly larger, which, of course, meant correspondingly less labour in winding about the supporting leads. Perhaps the finest of all the very early windows is just on the right as you enter the nave of Le Mans Cathedral.

(1*) Note the early Norman arch to the window embrasure, and the very broad border then customary. In England, the round Norman arch over a broad embrasure soon gave way to the Early English lancets, narrow and pointed at the top. In these latter, only narrow borders were possible.

(2) Closer inspection reveals that this scene is the Ascension. The drawing on these very early windows is so exactly like that on contemporary enamels and on mosaics, and stained glass begins as such a finished art, that there is no doubt it owes much to the enamel draughtsmen and to the earlier ones of mosaic. These very panes were among those that softened the light falling upon the baptism of your Henry II., for it was in this church that in 1133 Henry Plantagenet was christened, and we know that this glass was already in place, for it was the only window that survived the great fire of 1120.

(3) Next we see a bit from the oldest known

* The figures refer to the slides thrown on the screen.

window of St. Denis Cathedral, in whose vaults lie entombed so long a line of early French sovereigns. The abject figure at the bottom is Abbot Suger, who gave the window. Later on the donors grew to be far less modest. Note the bands of lettering, done by scratching upon blackened strips of glass. At this time the glass was coloured through and through in the pot, and is called pot-metal glass. Surface pigment was used only to delineate the features, and occasionally to bring out folds of garments. This pot-metal glass persisted much later in Italy than elsewhere.

(4) This other early St. Denis panel shows a Tree of Jesse, a design whose popularity endured throughout the entire life of mediæval stained glass. The vine springing from the loins of Jesse becomes more and more ornate as the centuries advance. Notice that we have here a much-peopled border, which was infrequent except in the case of Jesse windows. The lower right-hand figure was the donor of the window, and he holds its model in his hand, as was often customary.

(5) This glimpse of the choir chapels in Bourges Cathedral gives some idea of the lighting effects produced by medallion glass, truly "a dim religious light," which is here as excellently displayed below as, above them, greater illumination is afforded by the long row of forty-five small roses and the stately garrison of tall single figures.

(6) This Chartres window shows how the glazier combined different shapes of medallions so as gracefully to complete his space composition. The interstices he filled with what is called strap-work, generally of red and blue bits, so interwoven together as to produce a grape-juice purple, more mellow in colour than a single pane of purple. The four thousand figures on the 174 windows here still filled with their original thirteenth century glazing, tell in the minutest detail the life of the time. The windows along the nave aisles were presented by different trade guilds of the city, and fully set out their life and occupations. If the gorgeous set of thirty-six kings that used to adorn the Rheims clerestory justified its title of Royal Rheims, then surely at Chartres this glass, pulsating with colour, preserves for us the great heart beat of the mediæval middle classes.

(7) Angers Cathedral is especially interesting for the glass sightseer because he can there, more readily than anywhere else, compare the larger pieces of these twelfth century windows in its nave with the tiny-morselled ones of the thirteenth century in the choir, and see for himself how the latter glisten and glitter, while the early ones show but flat colour, warm in tone though it be.

(8) When Louis IX. (St. Louis) succeeded in obtaining a fragment of the true Cross, no more suitably sumptuous a receptacle could he imagine for it than a sanctuary whose walls should be sheets of light-admitting colour, and so there was built for him in three years' time (1245 to 1248) the Sainte Chapelle of Paris, where to-day it stands protected from the modern street life of that gay capital by the serious buildings of the Law Courts. This bower of light steeped in colour should be visited on a cloudy day, for the pursuit of stained glass is as truly a rainy day sport as is that beloved of Izaak Walton and other fishermen. On a sunny day the glass towards the sun will seem thin in colour, while that on the shady side will be dull and flat-toned.

(9) The north rose of Notre Dame is not only a *chef-d'œuvre* of lacelike stone-work and of design, but also very deceitful in its colouring, for although, thanks to the deft juxtaposition of its red and blue panes, it is a purplish window, it really contains no purple glass. Frequently these great wheels of light and colour enjoyed pleasantly familiar names. At Amiens the westerly, northerly, and southerly ones are called the Rosace of the Sea, of the Winds, and of Heaven respectively. The northerly one at Chartres is the Rose of Heaven, while at Lincoln the two roses are called the Dean's Eye and the Bishop's Eye. The skillful wall-adjustment of these great rosaces in French cathedrals is most delightful, and frequently, as here at Notre Dame, the giant wheel is balanced below by a gallery of sturdy worthies of the past.

(10) Such a line is to be seen just below the northern rosace of Chartres Cathedral. Note that in the early faces the glass is not white but brownish, making these gentry appear rather too sun-burned for Caucasians. This tint was better than would have been the untinted glass of the period, for it was not white but greenish. These great figures, "like watchmen on a leaguered wall," were frequently stationed around French clerestories during the thirteenth century, and served the useful purpose (by reason of their larger pieces of glass, and therefore less leads) of letting in from above much more light than was permitted below them by the mosaic medallion panes.

(11) The graceful symmetry of the Sens

Cathedral medallions is completely satisfying. It is no wonder that Thomas à Becket fell in love with them! We make this rash assertion confidently, for we know that he lived in Sens from 1166 to 1170. Pope Alexander III. spent two years at Sens immediately before that, and therefore both these famous churchmen saw the great architect, William of Sens, there developing the pointed arch, which meant the new Gothic architecture to all those church dignitaries who came thither from all over Europe to visit the Pope, and returned home to spread the gospel of Gothic. Later, in 1174, when the choir of Canterbury Cathedral was rebuilt, William of Sens was brought over to supervise the work, and the unfortunate architect met an untimely end by falling from a scaffold before his task was completed.

(12) That William brought his glassmen over with him needs but a glance at the early Canterbury windows to reveal. In those below and around "Becket's Crown," at the extreme easterly end of the choir, we see blood-sisters of those in the Sens choir chapels, and always the same well-balanced disposition of the medallions within their borders, which will continue broad in the French manner until the wide Norman windows yield to the narrower Early English lancet. These windows date from the middle of the century.

(13) A closer examination of the detail in these medallions shows spirited action on the part of their small inhabitants, and from them much is to be learned of the customs of their day.

(14) On the north side of Canterbury Cathedral's Trinity Chapel there is a very simple arrangement of the stories up and down the panes. It makes quite a human touch in Chaucer's "Canterbury Tales," when he has his pilgrims, as soon as ever they have entered the cathedral, fall to studying out the legends on the glass. His choice of title for this poem was a shrewd one, for he knew well how very many folk all over the kingdom had made this pilgrimage, and would therefore wish to read his "Tales."

(15) Quite different and particularly graceful is the fanlike adjustment of the panels employed on this chapel's southerly side, and one far from easy to compass. The mellow richness of the old reds and blues here are delightful.

(16) Although this chapel is not of sufficient width to allow the spectator to enjoy the glitter of the early glass, which needs a greater distance to develop, a recompense is found in the opportunity for close inspection and study of the Bible stories nowhere else surpassed. We cannot do better than follow the example of Chaucer's sightseeing pilgrims.

(17) At the very top of one of these windows there appears the only extant picture of the famous golden shrine, which contained the martyred prelate's mortal remains. It shows the saint issuing from the left end. So highly was this shrine venerated, that we are told that during the Jubilee of 1420 no less than one hundred thousand pilgrims visited the city in one day, and their gifts to it totalled a huge value. We know that so late as Henry VIII.'s time, he was able to find and seize twenty-six cart-loads of booty from about the shrine. It is a striking comment upon the charmed life borne by this glass that, notwithstanding its fragility, it should have preserved the only picture of this world-famous shrine. It must have been a true likeness, for it was so close to the original that any but a careful copy would have failed to tell its story to the pilgrims.

(18) One of the greatest glories of glass anywhere in the world is the group called "The Five Sisters," at York. That city, whose Minster alone contains over 25,000 square feet of ancient glazing, ranks with Rouen and Troyes as a great glass centre, and, like them, has many examples from each of the centuries when the art was at its best. These "Five Sisters" are of a type called *grisaille*; they told no story like those of the medallion type, but, on the other hand, they did not obscure so much light, and were therefore more practical. In England, your glaziers were fond of relieving the monotony of the *grisaille* panes, not only with occasional glimpses of colour, but also by outlines of plants, leaves, or vines. Here we have the leaves of the benet plant. There was also much fine old thirteenth century *grisaille* in Salisbury Cathedral, where, you will remember, there was a window for every day in the year, a door for every month, and a pillar for every hour. Old Thomas Fuller called it "an almanac of architecture."

(19) Another whim of these early artists was to use tints which, though seemingly inappropriate, were nevertheless so deftly adjusted to the general colour scheme as to be entirely satisfactory. Many a visitor to Poitiers Cathedral has gone away without realising that, in its gorgeous Crucifixion window, the cross is red and the hair of the Saviour blue! I know a sixteenth century window by Marcillac, in Arezzo, where the clouds are pink, but one does not notice it, so ingeniously readjusted is his

colour scheme. Figures as large as this one at Poitiers and as those at Chartres, were stationed along the clerestory lights of Rheims Cathedral, representing the first thirty-six kings of France, while just below each was the Archbishop who crowned him. On July 1st, 1429, these ancient worthies, already two centuries old, looked down upon the coronation of Charles VII. with Joan of Arc hard by. This splendid series were destroyed by the Huns, as were also the fine old windows at St. Quentin. Even that cold-blooded brute, Philip II. of Spain, when besieging St. Quentin in 1557, had decency enough to order his artillery to avoid breaking the ancient glass; but he only spared it for a later destruction by the "kultured" Prussians.

(20) While in Poitiers one should visit the church of St. Radegonde, not only because of its interesting glass, but because we can there study the transition from the thirteenth to the fourteenth century styles. The borders now become narrower, coloured medallions are being placed upon *grisaille* backgrounds so as to admit more light, and the upper part of the window is receiving more consideration, and therefore more graceful treatment. The figures on this window, taken together, form a picture of the Last Judgment.

(21) Speaking of better lighted interiors, it is to Troyes and its dainty eggshell of a church, St. Urbain, that one must go for perfection in this regard. Once upon a time there was a son of a modest shopkeeper there, named Jacques Pantaléon, who, marvellous to relate, became Pope of Rome. He never forgot his birthplace far away to the north, and there upon the site of his father's shop he caused to be erected, in 1263, a church with walls of stained glass supported by innumerable flying buttresses—one of the marvels of moyenage architecture. Here we have medallions to tell their sacred stories, but surrounded by fields of *grisaille* flooding the place with light.

(22) In the Cathedral of Troyes one finds the medallions in all their glory completely monopolising the choir chapels. They are of a richness one might expect in a city where all Europe yearly assembled for one of the greatest fairs of the Middle Ages—a fair of such significance in luxuries as to have embalmed it in our phrase "troy weight," still used by modern jewellers. Troyes windows became so widely known that one of them, a nave clerestory light from the Church of St. Jean, was demanded as part of the ransom of Francis I. after his capture at the battle of Pavia.

(23) Tours Cathedral is another in which one can study the product of the closing years of the thirteenth century. The borders are now distinctly narrow, and even then sometimes the medallions intrude upon them. This feature is best studied at Coutances in Normandy. The interior at Tours always impresses one as unduly narrow, and the reason is that the architect did not here avail himself of the usual device of slightly increasing the interior's width as the walls rose, done to offset the gradual contracting of the perspective to one looking up from below.

(24) Although our visit to France is now drawing to a close, because, with the arrival of the fourteenth century, there will be little in France to compare with its wealth of windows in England, the Cathedral of Sées and the great church of St. Ouen at Rouen will repay a visit before embarking for England. St. Ouen is almost completely glazed in one style, and the harmonious whole is most agreeable.

(25) Within the medallions and above the small figures we have, perhaps, all along been noticing little roofs, rather sketchy, but serving to indicate that the scene was indoors. These roofs are destined to develop and play a great part, not only in the drawing of our subjects, but also in the manufacture of the glass and in the amount of lighting it permits. At St. Ouen one sees pinnacles appearing above the people—of course, in the Gothic style then prevailing. Notice that there are as yet no pedestals, and that the figures and their canopies (as these sentry-box structures are called) do not yet aspire to fill the entire window space.

(26) Indeed, at St. Ouen, the canopy is still so unimportant a factor in glazing, that it is sometimes entirely omitted and the coloured figures set quite frankly against a *grisaille* background. Nowhere will we find so complete a series of patriarchs, saints, apostles, bishops, and abbots. It is not surprising that the English should at that time have so greatly admired French glazing. Five hundred square feet of French glass was brought over for Exeter Cathedral in 1302–4, and when more was needed in 1317, they sent to Rouen for it. Nor was this a passing fashion, for the contract to glaze Beauchamp Chapel, Warwick, made in 1447 by the Earl's executors with John Prudde of Westminster requires that there be used "Glasse from beyond the seas and no Glasse of Englande," so Prudde fetched his material from France.

(27) At Tours we will see an un-French sort of fourteenth-century window, for it is rich in

colouring like its contemporaries across the Channel, where no revulsion from the dim interiors of the fourteenth century had been necessary, because English skies had early taught the need of an adequate amount of *grisaille* to admit light. While the French, early in the fourteenth century, swung abruptly to light tints, deepening as the fifteenth century came on, the English (not needing the lighting reform) developed naturally from still strong hues inherited from the thirteenth century on through the fourteenth century, to lighter ones in the fifteenth. In sunny Italy deep colour continued throughout.

(28) Merton College, Oxford, has its chapel glazed entirely in the early fourteenth-century manner, and there the richly coloured figures within equally gay canopies are carried in one great band all around the interior, with much *grisaille* both below and above them, while at the top, the windows reach a handsome culmination in a style that truly deserves its name of "Decorated." These tracery lights were needed as a balance above to the groups of lancets below them, which by this time had come to replace the single lancet of the Early English period.

(29) The balance of colour and light in this work, provided an entirely satisfactory interior lighting. We are now coming to a period when a pane often had one colour on one side and another on the other. The French were experts at this and called it *verre doublé*, or lined glass. It was effected by re-dipping a partly blown bubble of glass into a pot containing liquid glass of a contrasting hue—for example, red into blue or yellow into red. When the bubble was cut open and held up to light, the effect of the first combination would be purple, and of the second orange. This process had always been used for red glass, the ruby being always thinned down in tone by a coat of uncoloured glass. Nor were the French contented with but two layers, for I know a fifteenth-century pane at Quimper, down in Brittany, that has six such layers or coats of glazing.

(30) Note the labels starting in front of the faces and swinging gracefully over the head and down the back. The decorative possibilities of these written scrolls or labels were nowhere so well worked out as in Germany. Sometimes one encountered written music similarly introduced, as at Warwick, and at Conches and Caudebec in Normandy.

(31) The treatment of the great East window in Merton Chapel is very pleasing, and this will remind us that, although the huge rose windows of France are for beauty and number unrivalled elsewhere, England may be equally proud of her wealth of splendid East windows. Their great expanse and the beauty of their treatment are as distinctively English as are the great wheel windows, French, or the unencumbered circular apertures called *ochio* (eye window), Italian, or windows showing great depth to their interpenetrated architecture, German.

(32) To visit a bower of light that rivals the Sainte Chapelle of Paris or St. Urbain at Troyes, we must return to York Minster and penetrate to its handsome octagonal Chapter House. Here one sees a glazing that perfectly suits the cloudy skies more frequent in this northern district than in sunny France. The east end of the small Dorchester church near Oxford is the nearest rival of the Chapter House in point of lighting. There the stone mullions of the window bear figures which, together with those upon the glass, make up a Tree of Jesse, the mullions themselves serving as the vine. The use of window mullions for this purpose here is as unique as is the woolen frame-work of a house in Joigny, France, likewise depicting a Tree of Jesse.

(33) This York Minster Chapter House dates from the time of Edward II. and III. Your "Decorated" period can show nothing better than the treatment here of the window tops, destined later, in the "Perpendicular" period, to lose their individuality and become stiffly regular and part of the window below them.

(34) The glazier has here employed four bands of late medallions in colour drawn across a field of *grisaille* enlivened with occasional touches of red and blue. This *grisaille* leans to grey rather than to the more usual greenish hue, and moreover, the quarries are cut into irregular shapes, less monotonous than the commoner diamond panes.

(35) No less delightful than the lofty brightness of the Chapter House itself, is the charming L-shaped vestibule leading thereto, entirely glazed at the same time and in the same manner. Its tall lancets are crowded with archaic figures and crude canopies.

(36) Very early in the fourteenth century there occurred a chance discovery destined to revolutionise glazing. In some way (and many claim the credit) it was found that chloride of silver, melted and dropped on glass, would colour the surface golden at that point. This was called yellow stain, and was promptly employed to depict hair, especially of angels, to enrich costumes, etc. But most important

was the effect it had upon the development of the canopy, for no longer was it necessary to lead in bits of yellow glass where needed, and therefore the simulated stone structures could be much more easily enlivened and extended by yellow stain than was theretofore possible. It is upon the Bell-founders' window, along the north aisle of the York Minster nave, that there appears the earliest use I know of yellow stain. Winston dates this window 1306 or 1307.

(37) A closer examination shows many pleasing details, among others the appropriate use of bells, so frequent throughout the border. This window, perhaps the finest of its type in all England, was the gift of Richard Tunnoc, Lord Mayor of York, who died in 1330. Above his effigy appears a small picture of the window.

(38) The fine West window, 56 ft. high by 25 ft. wide, presented in 1338 by Archbishop Melton, is as elaborate an example as the "Decorated" period can show of tasteful curvilinear elaboration of a window top. It should be noted that all the nave's aisle embrasures but two, and also all but two of its clerestory ones, retain their original glazing. Indeed, we have here the most extensive remains of English work of the early fourteenth century.

(39) The Lady Chapel of Christ Church, Oxford, shows a considerable advance in the "Decorated" period over what we recently saw at its neighbour, Merton College, for here the canopies are beginning to display a wider sweep and freedom, although still imposed upon a field of *grisaille*.

(40) The borders here are in agreeable proportion to the rest of the window, and the glazing of the tracery lights not so exaggerated as is often seen at that time.

(41) A similar treatment, but one more elaborate in design and richer in colour, is seen in that delightfully glazed sanctuary, Evreux Cathedral, in Normandy. Nowhere else at that time does the border receive so much attention. We have here a favourite French variation of *grisaille*, the so-called quarries, or diamond-shaped (*carré*) panels of uncoloured glass. They were not only easy to lead, but also their formal designs break up the surface agreeably, especially when touches of colour were judiciously introduced, which was often the case. Sometimes quarry windows were surcharged with gay heraldic blasons, but generally quarries filled in the space above and below the canopies, which as yet do not occupy all the lancet.

(42) Returning to York we find in the north wall of St. Dennis' nave an interesting example of an early "Decorated" canopy pushed tight up against the top of the lancet, forecasting how the glazier will presently come to fill the whole of its surface with his picture, and entirely exclude the *grisaille*.

(43) This complete filling of the window with the canopied figures is admirably exemplified in the Antechapel lights at New College, Oxford.

(44) These really mark the transition from the "Decorated" to the "Perpendicular" period, for although the canopies have sufficiently developed to have acquired pedestals and to fill the entire embrasure, there is still no perspective shown in their architecture, which is quite flat. Besides, the surface colour is not only smeared on with a brush in the "Decorated" manner, but also stippled on in that of the "Perpendicular" school. We see but a single figure within each canopy instead of the groups that will come later.

(45) The nave of St. Dennis Church, York, shows another advanced example of the "Decorated" canopy light, embellished by a rich border which was lacking at New College.

(46) No more elaborate minarets and spires are to be found in the canopies of this period than in the south-easterly window of St. Martin, Micklegate, York, even though they do not boast of pedestals. Notice that so insistent is the glazier that his *grisaille* shall admit its full quota of light, that the donors' figures thereon are only outlined instead of being full coloured as usual. These donors are going to grow in importance, until in the sixteenth century in France we shall find them unduly intruding upon the religious subject of the window, and even exceeding in size its principal personages. Indeed, at Montmorency, near Paris, Guy de Laval, the donor, occupies the central panel of the Crucifixion window; while at Champigny-sur-Veude, in Touraine, the chapel windows showing thirty-six kneeling donors, all members of the Bourbon Montpensier family, clearly prove how much more attention was then paid to such portraits than to the historical or religious subjects of the window. The English glaziers, however, never lost their sense of proportion in this regard. In Italy donors are almost never seen.

(47) A detail of the two right-hand panels here shows the church's patron saint dividing his cape, in strict accordance with tradition. This window is rendered especially brilliant by the generous use of red in the background.

(48) The south-east window of York Minster chancel is a gorgeous example of this period's

glazing, although the mullions of the tracery lights are not so fortunate in their form or their contents as some we have already seen.

(49) The most charmingly glazed of the many small churches of York is All Saints, or All Hallows, as it is sometimes called. Here to the left we can see the space below the "Decorated" canopied saint filled in with a small scene in colour, instead of the pedestal then coming into fashion. Note that the elaboration of uncoloured panes in the canopy tops on the left lets in as much light as does, on the right, the *grisaille* above the less developed canopies below. The right-hand window is, of course, earlier than the other.

(50) A detail from one of the northern lights here shows that perspective is now beginning to appear in the drawing of the canopy.

(51) But now it is time to turn from the "Decorated" to England's greatest period in stained glass, the "Perpendicular," lasting from 1380 to 1500, or from just before the last Plantagenet was succeeded by three Lancastrians and they by three Yorkists, until the accession of a Tudor (Henry VII.) marked the end of the War of the Roses. We shall remember as the chief characteristics of the "Decorated" period, the decorative treatment of the tracery lights, deeply rich colouring, the introduction of yellow stain, the development of the canopy but without a pedestal, glass with several layers of different colour, increased use of leaves, vines, etc., and shading smeared upon the surface. Now we come to shading which is stippled on, to increasingly lighter and softer tints in England (whilst an opposite tendency is seen in France), greatly elaborated canopies in both lands, and in England stiffly parallel mullions and loss of independence by the tracery lights. The most impressive of all this new period's product is the amazing East window at York Minster, 78 ft. by 32 ft. in expanse. Its only rival is that in Gloucester Cathedral, 72 ft. by 38 ft., commemorating the English knights who fought at Crécy. So huge is this York window that one hardly notices the gallery leading across the face of its 200 panels of figures. We know all about its construction, for the original contracts, dated 1405, are preserved and call for its completion in three years. It is no wonder that its citizens voted a tun of French wine to the Roundhead Fairfax for protecting their ancient windows when he besieged and took the city. No such decency was displayed by the Huns outside of Rheims, even though it was the best equipped city in the world for purchasing immunity with wine.

(52) At St. Martin's, Coney Street, York, the West window, given in 1447, shows an elaborately complete embrasure of "Perpendicular" construction, complete with the outswinging curved mullions in the traceries to avoid too monotonous an uprightness. Below, where the shadow of an adjoining building might have robbed the figures of their brilliancy or interest, the space is intelligently filled with elaborate quarries.

(53) The detail of this window repays inspection, as showing excellence of drawing and shading. This reminds us that opera glasses will frequently prove useful on stained-glass tours, and will reveal to us many of those quaint details in which mediæval artists revelled. For example, the golden tongues of flame in the Pentecostal window, or the Fall of Manna one at Montfort l'Amaury, near Paris, or the ruby glass used for the Red Sea through which the Israelites are crossing, at Caudebec near Rouen.

(54) We must not be kept from visiting All Soul's College Antechapel at Oxford by Prideaux's comment in 1674, that "it is a scandalous place and full of fast gentlemen." It has carefully drawn and coloured lights in the full "Perpendicular" manner. The pedestals have so much perspective as to make them very near to the German Interpenetrated style.

(55) Quite unique is the "Prick of Conscience" window at All Saints, York, showing under their squatty canopies the fifteen last days of the world as described by Richard Rolle, who died in 1349, while below are nine devout donors, kneeling in a row. The story begins at the lower left-hand corner and goes to the right, following the order usually then employed by glaziers. There are, of course, occasional exceptions to this general rule; as, for example, in the south choir aisle at Great Malvern, where, though the story develops from left to right, it begins at the top instead of at the bottom.

(56) Another famous window in this same church is one called "The Six Corporal Acts of Mercy," of which, perhaps, the most popular is the upper central one—"Giving Drink to the Thirsty." In its elaborate canopies and well-balanced scenes, this window is much more conventional than the unusual and catacomblike treatment of the "Prick of Conscience" window. In France this elaboration of light-admitting canopy reached such a point that at St. Lo they monopolise fully four-fifths of the entire embrasure, leaving but little for the solitary

saint in colour marooned in the midst of their shimmering magnificence. These windows were presented to the citizens by Louis XI. after their gallant repulse of the Bretons. In sunny Italy the canopy work continued to be done in strong rich tones, although this was, of course, partly due to copying the richly coloured marbles there so much used. On Marcillac's windows in Arezzo we see green malachite, red porphyry, polychrome marble, and much gaily coloured pavement.

(57) In the lowest central light of the East window of Holy Trinity, York, that sacred subject is depicted as three men each of about the same size, which is, so far as I know (and I have notes on over 20,000 windows) the only case of such a portrayal of the subject.

(58) St. Taurin, at Evreux, is another fine example of late fifteenth-century glazing, especially in the apse, for remember that in crossing the Channel we have robbed the glazier of the great flat expanse at the east end of English interiors, and that we are once more back in the home of the curved apse. Across the back of each canopy runs a richly decorated curtain, then rigorously required by the conventions. In the fourteenth century there was seldom more than one figure within each canopy, but now we have large groups of them. Some canopies here are very incongruously inhabited, as, for example, that group which shows the saint rescuing a lady from some sharp pointed flames while five smug onlookers piously approve the discomfort of the exorcised red imp.

(59) Perhaps the most ornate window of the entire period in France is that in the chapel of of Jacques Cœur at Bourges. That rich banker, Treasurer of France, who financially befriended Charles VII., left behind him not only a sumptuous residence in that city, but also this surprising window, where splendid costumes vie with the glittering star-spangled ceiling of the most elaborate Gothic dome ever attempted in glass painting. The way in which the picture disregards the mullions and sweeps across the whole embrasure forecasts a common practice in the sixteenth century.

(60) It is well that we have crossed the Channel because, having now reached the sixteenth century, the fewness of its examples in England, even including the magnificent and, perhaps, unsurpassed interior of King's College Chapel, Cambridge, are as nothing compared with the wealth of windows then everywhere blossoming in France. We shall now find larger scenes, more use of perspective, greater diversity of colouring, enamelling of paint upon the surface, carelessness in allowing leads to stray about instead of confining them to outlines, and classic instead of Gothic canopies and architecture generally. A window at Troyes, of the Tree of Jesse type, shows that although the pictures are now painted in a bolder spirit, the old curving tracery lights, long since Perpendicularised in England, still persist in France. In France the descendants of Jesse almost always appear as blossoms on the vine, but their earlier English prototypes usually stand within small cartouches formed by its convolutions.

(61) The gorgeous southerly rosace in Sens Cathedral, depicting the Last Judgment, shows how skilfully the Renaissance glaziers could accommodate themselves to any sort of embrasure. This and the northern rosace were done by three great glass artists, brought hither for that purpose from Troyes in 1500. The French *peintre-verrière* was always more independent of the architect than his colleague in England, where the narrow, almost spindling lancets provided during the Early English period as clearly modified the glazier's cartoons, as in the Perpendicular period did the stiffly upright panels below and the equally upright pill-boxes above in the tracery lights.

(62) It would not be respectful to the city in which your distinguished Society has led so long and so useful a life did I close with no reference to certain really fine examples of sixteenth-century glazing to be seen here in St. Margaret's, Westminster, and St. George's, Hanover Square. In view of the number of weddings that take place at St. George's, it is, perhaps, appropriate that the old glass across the chancel should be a Tree of Jesse.

(63) This Flemish glass, originally made for a church in Mechlin, Belgium, has been tastefully readjusted to its new home in the three eastern embrasures, but that it was originally a Tree of Jesse and all one window is quite clear.

(64) The labels and the portions of the vine alone would prove that fact. I know of no Jesse anywhere possessing such large figures, for they are even larger than at St. Etienne in Beauvais, where, oddly enough, appear contemporary portraits such as Francis I. and Henry II. instead of Biblical worthies. So in the Wine Press window in the Sacristy of Saint Etienne du Mont, Paris, one can recognise the features of Pope Paul II., Charles V., Francis I., and Henry VIII. At Vincennes Jean Cousin placed Diane de Poitiers among the Holy

Martyrs on one of his gorgeous windows. Henry II., who appears near-by as a Knight of St. Michael, must have had small sense of humour to have countenanced such a disposition of his friend!

(65) The East window of St. Margaret's, Westminster, is not only beautiful, but also it has probably suffered more vicissitudes of travel and ownership than any window in the world. On the right side is St. George, and below him the only authentic portrait we have of Arthur, Prince of Wales, while across from him, in the lower left-hand corner, kneels Katherine of Aragon, Prince Arthur's *fiancée*, and, after his death, first wife of his brother, Henry VIII. Above her head is her badge, the pomegranate. It was because of this reminder of his wife's former betrothal to his brother that Henry VIII. started this window on its travels.

(66) It was ordered in Dordrecht, Holland, in 1499, by Ferdinand the Catholic and Queen Isabella, as a gift to Henry VII. to commemorate their daughter's marriage to his son, Prince Arthur, and was destined for the Henry VII. Chapel at Westminster Abbey. It took five years to make, and meantime Prince Arthur died in 1502. His brother, Henry VIII., did not place it in the Westminster Abbey Chapel, but gave it to the Abbey of Waltham. Upon the dissolution of religious houses in 1540, the Abbot transferred it to his private chapel at New Hall, Essex, which, strangely enough, later passed to Sir Thomas Boleyn, father of Queen Katherine's successful rival. Upon his death Henry VIII. seized New Hall on behalf of Anne Boleyn's daughter, Elizabeth. Later, Queen Elizabeth gave New Hall to the Earl of Essex, who sold it to the Duke of Buckingham, and his son sold it to General Monk, who preserved the glass in chests safe from the iconoclastic zeal of the Puritans. John Olmius, New Hall's next owner, sold it for fifty guineas to John Conyers of Copt Hall, who resold it in 1759 to St. Margaret's for £420.

(67) A number of Dutch glass painters, the Crabeth Brothers, Von Linge, and others, worked in England towards the close of the sixteenth century and even a little later, and one of the best specimens of that school's handicraft is to be seen in Wadham College Chapel, Oxford. It is placed in older embrasures, as the Perpendicular mullions reveal.

(68) By this late date glaziers had come to indulge too frequently in painting their pictures on the glass surface and then firing them, giving a sort of enamelled result. This was vastly easier than the laborious leading-in of numerous bits of coloured glass to make up the picture.

(69) This enamelling of glass has, however, two serious drawbacks. One was that where shadows were required, the glass was so obscured by paint as to lose its translucence, and the other was that, in the course of time, bits of this enamelled paint peeled off.

(70) This is unfortunately noticeable, not only in the Wadham windows, but even more so in one at the north-eastern corner of the nave in Christ Church Chapel, Oxford. These later paint-obscured panes make us sigh for the rich pot-metal glass of the early men, who, when they needed dark tones, laboriously leaded in bits of deeply-coloured glass, which gave the required hue without obstructing the light.

So ends our little journey up and down England and France, and now for a few parting words. It would be a fine thing for the cult of ancient glass if such a company as are here assembled could be persuaded to see for themselves the treasures of mediæval colour still preserved after so many centuries for the delectation of us moderns. My poor pictures give no idea of how the originals can and will delight you. They themselves must be seen to acquaint you with their real glories in "the bugle cry of red, the limpid confidence of white, the repeated hallelujah of yellow, the virginal glory of blue-all, the quivering crucible of glass" (Huneker's translation from Huysman).

If you will permit what may seem a digression from the purely artistic standpoint of considering stained glass, it seems to me that the subject opens a window into the field of metaphysics, something which is now receiving more of the attention it deserves than formerly. Stained glass is not only a decoration for a window, not only an artistic addition to architecture, but it is a manifestation of matter being penetrated by something *not* material. It not only illumines, brightens, and decorates interiors of buildings, but it has other metaphysical properties as yet but little understood. We know from experiments conducted at the Sorbonne, Paris, not long before the outbreak of the war, that glass of certain colours distinctly encouraged the growth of certain vegetables. Why? That remains yet to be determined. In Aubrey's "Anecdotes and Traditions" we read: "The curious oriental reds, yellows, blews, and greens in glasse-painting, especially when the sun shines doe much refresh

the spirits. After this manner did Doctor R. revive the spirits of a poor distracted gentleman, for whereas his former physitian shutt up his windows and kept him in utter darknesse, he did open his window lids and let in the light, and filled his windows with glasses of curious tinctures, which the distempered person would always be looking on, and it did conduce to the quieting of his disturbed spirits."

Here is something which one may dismiss with the slighting observation that it is quaint, or recognise as pointing to a *terra incognita*, as yet not "dreamed of in our philosophy." In that amazing book, "The Education of Henry Adams," the autobiographer, himself a learned lover of ancient glass, insists that the entire history of the world should be divided into but two epochs—firstly, that before the discovery about 1893 of the X-ray and of radio-activity (which period he styles the Sensual Epoch); and, secondly, the Super-Sensual Epoch, which, after those great discoveries, turns all our scientific investigation towards the Fourth Dimension, out beyond the limitations of the five senses. Stained glass, considered from this super-sensual angle, affords a fascinating outlook into the Fourth Dimension, and at its very threshold reminds the sightseer that to become something more—to become a seer—he must admit that things material are, like our windows, shot through and beautified by something beyond the material, and therefore subject to higher laws.

I have recently been in Japan, and there, last autumn, in the crysanthemum show at Hibiya Park, Tokyo, I saw more than one example of a great plant burdened with scores of blossoms which, although of contrasting colours, all sprang from the same root. This surprising result was, of course, obtained by an elaborate system of grafting stems from different plants on to a central one. This particularly interested me because I myself am such a product, for although of old Devonshire stock, I am also half Dutch through my mother's family. Just as it was both interesting and instructive in Tokyo to yield to the many-coloured lure of the great chrysanthemum plant, and trace back from the brilliant blossoms to their junction with the parent plant, so I conceive it widely profitable for all of us Anglo-Saxons to permit—nay, to encourage—the gaily-hued charm of your old windows to lead us back to the study of the days before our ancestors branched out from our common homeland in the British Isles.

DISCUSSION.

MR. MORRIS DRAKE said he did not think there was anything to be said about the paper, except to express gratitude for the very straightforward description of the developments of glass and for the extraordinarily interesting pictures illustrating that development. The pictures showed exceptionally fine examples. The only example he should like to have seen added was "La Belle Verrière," at Chartres. But with that one exception the lecturer had managed to capture pictures of every important window in the west of Europe. He had been much interested in the paper and had enjoyed it immensely. As one went through the story of stained glass one always came to the middle of the fourteenth century. Prior to that period there was the French stained glass, and after that period the English. With the one exception from Canterbury he thought the first half of the pictures shown that evening were entirely French, and after that, with the exception of one or two examples, the pictures showed a steady development in purely English windows. It was rather a queer thing to reflect on that turn-over in the middle of the fourteenth century, and he might point out a very curious parallel at the present moment. About the year 1350 there was almost exactly a counterpart of the social conditions that existed to-day. At that time the country was fresh from wars in France, the pestilence was raging (to-day influenza), labour troubles were abundant, and legislation was trying to keep labour in its place. To anyone who had been engaged in the recent disturbances on the Continent nothing was more remarkable than the fact that during two periods of the war the reports of the daily movements of the army might have been taken out of the pages of Froissart. For the ordinary every-day Englishman to see men in steel caps and leather jerkins on the banks of the Somme was opening the pages of Froissart again. Following the period he had just mentioned there was a perfect fever of building, from the middle of the fourteenth century to the end of the fifteenth. Dating from that period there was a type of tower common in Devonshire, which was known all over the world, and in the adjoining county of Somerset a window so well known as to be called a Somersetshire window. He thought there would be an outburst of building now following on the recent disturbances, and there would be a re-birth of architecture such as took place then. All craftsmen engaged in architecture and the allied arts should immediately set their houses in order. The glass painters had recently done their best to set their own house in order by forming the Society of Master Glass Painters, and he hoped they would be able to gain recognition from the Royal Society of Arts and some aid in attaining their aims, which were to encourage a knowledge of stained glass and an increase of skill in its practice, and preserve and keep in the country our heritage of ancient glass. English glass was irreplaceable,

and it was going out of the country in a very large amount. There was a window at South Kensington at the present moment, three panels of fine very early thirteenth or perhaps twelfth century work. The fourth panel was in a collection in Norfolk, and that panel was in great danger of going to America. He was very glad to see the author come to England and study English examples, but he did not see why he should have them to study in the Metropolitan Museum at New York. If the new Society could do anything to keep the glass in this country and induce people to come here and look at it it, would serve a double purpose, and if the Royal Society of Arts could help in that direction the new Society would be exceedingly grateful.

Professor J. M. Thomson, F.R.S., did not feel he was at all in a position to say anything upon the subject except to thank the lecturer for the extremely interesting paper he had given and the compact historical way in which the matter had been presented. He would not venture to soar into the metaphysical question of the effect of coloured glass upon human beings mentioned towards the close of the paper, but he knew that coloured glass had a distinct physiological effect. In conducting photographic classes at King's College, where the developing room was lit by large windows of ruby glass, the red light exercised in many cases an effect on the pneumogastric nerves of the students. At the commencement of the Term some of them had to leave the room on account of a feeling of sickness. After some time they became accustomed to the light, and the feeling of nausea passed off. As a Member of Council he sincerely thanked the lecturer for the extremely able and interesting paper he had given.

Mr. Reginald Hallward wished to add his thanks to the lecturer for the very remarkable series of reproductions he had shown. He should have been glad, however, if a little more could have been said with regard to the particulars of the method of production, because after all that lay at the root of the question of their beauty. If it were possible to have said something as to the way craftsmen in the earlier periods worked, how far the work was personal to themselves, and how far it was carried out by firms with a large number of glaziers, it would be of value. It might be within the knowledge of many that there was in existence the original contract for the famous east window at York Minster, and the Chapter of that day showed a perception of what should govern the production of good work. They made it a condition in the contract that the artist should carry out the work himself. He was to receive twenty-five pieces of silver extra if he did it in a certain time, the time given to him being very ample. No one wished literally to interpret that an artist should do his own work and should have no help at all, because that might be impossible with a glass window which might be perhaps 70 feet high; but the temper and spirit in which the work was done absolutely governed the work when it was completed. When he heard that the Guild of Master Craftsmen in Glass was being formed he attended a meeting, and quite anticipated that he should hear, as in the old Guilds, some consideration given as to the terms in which glass painters carried out their work. He should not expect them to be limited companies or that the genius of one man should be worked through glaziers and painters. He was not offering an expression of view that work was not done now as honourably and sincerely as he should expect his own work to be admitted to be done; he only asked those who cared for the prospects of stained glass to consider the whole matter. It had been said that the object of the new Society was to improve the quality of glass. It seemed to him it was necessary to adopt methods by which better results could be produced. Unless some limitations of employment and some understanding existed that the work of the Guild was subject to some approval, or that a member must pass out of the Guild if he merely became an employer and not a producer, some such conditions as operated in the Guilds of mediæval times, the Guild would become a complete farce on that side of its work, although on the side of the question of the protection of glass in this country he had no doubt it would do very useful work. As an old worker in glass whose work had some reputation in the country he saw no hope of any progress except by the worker himself retaining his own independence and producing work by his own hand with only such little assistance as was absolutely essential to the doing of it.

Mr. Noel Heaton said the paper had awakened many happy memories of the originals, and also had revived a very great regret, because it so happened that in the summer of 1914 Mr. Drake and he decided to take a trip together to study the old French glass, but that trip was stopped by the war. They drew up an itinerary, and came to the conclusion that they could not get through the tour in the one year. In their itinerary they were very largely guided by the author's excellent book, "Stained Glass Tours in France." The very finest example of glass in the French cathedrals was that at Chartres, and in their first tour they made Chartres their starting-place, and finished up at Troyes, and on the journey took some 400 photographs of glass. They came back with the firm intention of going over the following year and finishing the job, starting from Amiens, and, as a matter of fact, they both of them did go to France in 1915, but on a very different errand. He had never seen the results obtained from the first portion of the tour until he saw some of the slides shown that afternoon. If they had gone to Amiens and Rheims and Soissons first they would have obtained valuable photographs of the glass that had been destroyed. He himself was more particularly interested in the technical side of stained glass. The lecturer had shown one or two

examples of the extraordinary vandalism that occurred in the old days, and that was not altogether a thing of the past. He remembered at York being told that there was a certain church in that city which had a very fine fifteenth century window, and the churchwarden decided that it was out of date. Someone who was interested in stained glass asked that when it was taken out it should be given to him. The window was taken out, smashed up, and handed over in fragments under the impression that he wanted the lead. Fortunately that sort of thing was passing away, thanks to the activities of men like General Sherrill, who were impressing on the public the great beauty and value of stained glass. He was sorry that the appreciation of such glass was very much keener elsewhere than in England, because, if care was not taken, there would be very few examples left in this country. Twenty years ago people would not look at thirteenth century stained glass, whereas now collectors would give almost any price for it. He thought very few people ever saw a stained glass window in the proper sense of the word. Anyone who wanted to know what stained glass was had to view it in a very leisurely fashion and spend time on its study. For seeing the "Five Sisters" at York one must sit just within the door at sunset in order to see how beautiful the picture was; as the building became dark, the window lit up, and throbbed and glowed in a wonderful sort of way.

The Chairman, in proposing a vote of thanks to the author, said the thanks of the meeting had been accorded so thoroughly and eloquently by very nearly every one of the preceding speakers, that it was hardly necessary for him to enlarge on the theme beyond saying that the Society was more than grateful to General Sherrill for coming and placing his wonderful life-long and most accurate knowledge at the disposal of the meeting. He was happy to think that General Sherrill had in the records he had shown some permanent memorial of such delicate and fragile work.

The motion was carried unanimously.

General Sherrill briefly responded, and the meeting then terminated.

TRAINING OF HYDRO-ELECTRIC ENGINEERS.

In March, 1919, Professor A. H. Gibson read before the Society a paper* in which he pointed out the necessity for developing water powers within the British Empire, and, as a corollary to this, the need for providing in this country opportunities of training for Hydro-Electric Engineers. While definite courses are conducted in such institutions, for example, as Cornell and McGill Universities, and in many of the Continental technical institutions, very little is done in the British universities and colleges, compared with, say, the courses of instruction in the study of steam engineering. As a consequence of this, the design and manufacture of hydro-electric machinery have generally been entrusted to Continental firms, and of the few really large hydro-electric installations, for which British establishments have been responsible, the greater part of the hydraulic machinery has been made abroad.

In these circumstances it is interesting to learn that Sir W. G. Armstrong, Whitworth and Co., Ltd., have now taken up the manufacture of water turbines, and have established a Hydro-Electric Section of their Civil Engineering and Contracting Department. They are, therefore, in a position not only to deliver water turbine units, but to undertake the hydro-electric plant construction. One of their chief difficulties, however, is that which was adumbrated by Professor Gibson, viz., the difficulty of obtaining British-born hydro-electric engineers.

It would appear that this new departure presents a very favourable opportunity to the many who have taken up the study of water power in recent years, as a result of the greatly increased interest in the subject, to turn their acquired knowledge to good purpose, and to increase it further. Fellows of the Society may know of Engineers who may be looking for such opportunities in the Hydro-Electric world, and a very useful purpose would be served if they would bring this matter to the notice of such individuals.

THE BRITISH INSTITUTE OF INDUSTRIAL ART.

The first exhibition of the British Institute of Industrial Art was opened at 217, Knightsbridge on May 31st. The fact that the Institute, with Sir Hubert Llewellyn Smith as its chairman, has been established by the Board of Trade and the Board of Education, with a view to combining for the first time the educational and the productive sides of industry, leads one to hope that it will efficiently deal with the vital problem of how to bridge the gap that despite all previous efforts still exists between the artist and the manufacturer.

That art can enter industry as an aid to production, ensuring that excellence of design and workmanship which will best lead to *quality* production, hardly requires demonstration. And equally obvious is the corollary, that quality production, by which labour and raw material are used to the best possible purpose, ensures successful competition on the world's markets; a vital matter for our country at all times, and especially at the present juncture.

An effort has been made to demonstrate in this first exhibition that the co-operation of artist and manufacturer already exists, and can be extended. Attractive furniture (not of the "arty" type, but

* "British Engineering and Water-Power Development (The Training of Engineers)," *Journal*, Vol. LXVII., pp. 255-9.

serviceable and simple enough); a wide range of textiles (from the sumptuous three-pile velvets invented by Sir Frank Warner and Macclesfield's best silks, to the hand-woven wools from Ditchling or the printed cretonnes from London and the North); decorative panels (by Rowley and others made of quite ordinary woods, but wrought with uncommon skill); Armitage's carved and gilded frames (only comparable in their gilding to that by such masters in another craft as Grally Hewitt); Hall Thorpe's attractive hand-coloured prints, gorgeous Morris tapestries, one of which represents "The Arming of King George," after Bernard Partridge, all come to show how "things of beauty" may vary in material as well as in style, and be available, not for the lucky few only, but for all.

The first gallery of the exhibition is devoted to exhibits by individual craftsmen, where works may be purchased and carried away. In the Trade section one sees porcelain, pottery and earthenware. Doulton of Lambeth and Doulton of Burslem show their finest works side by side. Mr. Bernard Moore shows us his rouge flambe and other unique pieces, and near by we see the pure porcelain of Minton: Pilkington shows new and interesting tiles, in addition to larger works by Forsyth and others. Messrs. Josiah Wedgwood contribute four distinct types of work, all splendid examples of the potter's craft. The simple ware manufactured with skill and taste by Carter of Poole, and the work of numerous exhibitors from Stoke introduce to the public ceramics of good design, colour and workmanship within the reach of all.

In the Textile section, Messrs. Warner and Son, Messrs. Robersons, Messrs. Morton, Messrs. Tomkinson and Adam, and Messrs. Harrods exhibit large and entirely different exhibits, and in another gallery cretonnes and printed goods of varying kinds make a gay display. The chief exhibitors in the latter section are Messrs. Ferguson, Messrs. Turnbull and Stockdale, Mr. Foxton, Messrs. Stonards, The Ramsden Wood Print Works and Messrs. Story. The Design and Industries Association also have a collective group of interesting work.

The problem of beauty in all objects of the home is proved thereby not to be one of cost. Nor is it one of handicraft *versus* machine production; indeed, in many cases we find that unless the desired works be produced by machinery and in quantities, the prices will remain so high that for all practical purposes the problem remains unsolved. Here, again, it is the duty of the designer to bear in mind the conditions of machine production, to conform to them, and to avail himself of their possibilities to the utmost. There is not a large display of cabinet work, but space has already been requested for the next exhibition by intending exhibitors who through business pressure are unable to be represented this spring. Beside the sumptuous productions of Messrs. Higgs and Hill, designed by Charles Spooner, and the unique work by the late Gimson, and Waals, his successor, it is interesting to see the more simple work by such men as Palmer Jones.

While in the galleries, it was pleasant to hear an authority state "that a new organism had sprung to life and started its task with purposeful earnestness." In addition to the Exhibition an Information Bureau has been opened, which supplies practical data of all kinds to artists, to manufacturers, to buyers and to students. Travelling exhibitions and various forms of propaganda at home and abroad stand next on the programme, and will, it is hoped, considerably extend the range of the Institute's usefulness. Since the opening of the Exhibition the Institute has been approached by two leading bodies in the country with a view to future co-operation, which would seem to indicate that the efforts of the Institute are being favourably received. The galleries will remain open on Tuesday and Thursday evenings and on Sunday afternoons, and it is hoped that it will become increasingly popular through the support of all lovers of art as applied to industry.

[It is hoped that all readers of the *Journal* will support this much looked forward to Exhibition scheme now that it has thrown open its doors. It will be remembered that the question was first publicly discussed at the Society's Rooms in October, 1918. As the *Times* pointed out in its columns on 28th May last, "the problem before the Institute goes to the roots of civilisation," and Fellows are particularly requested to interest the nation in the objects set out in the above article, and thereby link up more closely than ever the aims of the Institute with those of our own, which after all are one and the same.—ED.]

MANUFACTURE OF COCONUT FIBRE IN TRINIDAD.

There are three factories in Trinidad producing coconut fibre. The process of production, according to a report by the United States Consul in Trinidad, is as follows:—

The husks are first battened down in concrete tanks and soaked in water for about five days, after which they are passed through a crusher composed of a pair of cogged rollers pressed together by heavy springs. The cleaning mill consists of a rotating drum about thirty inches in diameter, fitted on the periphery with steel spikes. In front of this drum there is a pair of small feed rollers, through which the husk is fed and held against the rotating teeth. The husk is passed through these rollers as far as possible without letting go of it. It is then drawn back and turned end for end. After that it is turned over and the operation is repeated. The long-staple fibre, generally known as the brush fibre, remains in the operator's hands, and the short-staple fibre, known as mattress fibre, is drawn into the machine. So far as the long-staple fibre is concerned, it is now finished except for drying.

The mattress fibre, containing all the refuse, is

taken from under the cleaning mills and put in the willowing machine, which is an inclined revolving drum covered with half-inch wire mesh, and containing revolving beater drums mounted on a shaft which rotates in the opposite direction to the drum. The fibre is then spread out in the sun to dry, which in fair weather can be done in a day. Finally, it is hydraulically pressed in bales, measuring 20 by 20 by 40 inches, and weighing about 180 lb.

The commercial prospects of coconut fibre are not promising, owing to the increased cost of manufacture and the rapid fall in prices obtainable. The increased cost of manufacture is due to the high cost of fuel oil and the excessive freight rates. It is stated that the cost of freight amounts to one-third of the gross value of the fibre shipped. On the basis of the information available, the production of coconut fibre in Trinidad is not regarded, under present conditions, as a very profitable undertaking.

PRODUCTION OF CANDELILLA WAX IN MONTEREY.

There are great quantities of Candelilla shrub in the Monterey district. It is found chiefly in the Montemorelos and Galeana districts, in the north-eastern part of the State of Nuevo Leon, also in the Bustamante and Villaldama districts, in the northern part of the State. This shrub is grown entirely without cultivation. The average shrub is about 25 inches high; some plants, however, are about 40 inches in height.

While there are, says the United States Vice-Consul at Monterey, several factories making candelilla wax in that district, there was only one large one in operation last year (with a daily output of about 662 lb. of wax) due to the low price of the product in the United States. Another large factory in Monterey is reported to be in contemplation.

After the shrub is pulled out of the earth it is placed in wooden tanks of water which is heated to the boiling-point. At the moment of boiling a certain proportion of sulphuric acid is put in the tanks. As soon as the acid comes in contact with the wax it comes to the surface and is collected and put in receptacles until it congeals; it is then put in another tank where steam is used to dissolve the wax, adding sulphuric acid a second time. The wax is then in a refined state and is allowed to harden in certain moulds. It is then ready for shipment. The wax can also be extracted by direct fire.

THE COMMERCIAL SITUATION IN ITALIAN LIBYA.

Italian Libya now comprises the two Provinces of Tripolitana and Cyrenaica, and lies along the north coast of Africa, between Tunis and Egypt. The extreme northerly point of Libya is at about 33° north latitude; the southernmost point is unknown, as the territory runs south into the unmapped Sahara indefinitely.

All of Italian Libya was taken from the Turks and Arabs in 1911. The whole interior and a considerable stretch of coast-line was recaptured by Arabs, Turks, and Germans during the war. But on April 24th, 1919, a final armistice was signed by the Arab chiefs, who had continued tenaciously to carry on hostilities long after Turkish and German aid had been withdrawn. By the terms of this armistice Italy gained full possession of Libya, as described above.

Only an estimate may be made of the population of Libya. A guess would place it at about six millions, of which perhaps 30 per cent. are Arab, 40 per cent. Negro, 20 per cent. Jewish, and rather less than 10 per cent. European, comprising Italians, Greeks, and Maltese. The Berbers—the original inhabitants of the country before the great Arab invasion of the eighth century—are so intermixed and merged with Arabs, Negroes, and Jews, that they can rarely be distinguished. The Arabs proper—Bedouins along the coast, Tuaregs and savage tribes inland—dominate absolutely.

Commerce is almost entirely in the hands of the Italians at present, though Maltese and Jews act generally as their agents in trade with the natives. The commercial language and currency are Italian English, however, may be used in correspondence, though Italian is naturally to be preferred.

According to data submitted by the office of the United States Commercial Attaché at Rome, since 1887 there has been a serious decline in the volume of trade of the country, due largely to the deflection of the caravans from the interior from Tripoli, their old gateway. Tripoli, 1,200 kilometres due north of Lake Tchad, has always been the natural Mecca for the caravan trade. The route is comparatively easy; at no point is water more than three days from well to well. Although the tribes of the desert have always been comparatively friendly in this region, it must be remembered that the Bedouin is by inheritance and training a brigand. Before any real security of passage may be assured, a competent and adequate military force must be posted all the way from Tripoli to Tchad. In the past caravans of 500 camels and 200 men have been attacked, despoiled, and dispersed; and since the Italian occupation in 1911 these depredations have increased, until now practically no caravan trade remains. In Cyrenaica a few small caravans still arrive. In Tripolitana the arrival of a single unimportant caravan of twenty camels in June last was considered remarkable.

Outside of the caravan trade the chief exports of Libya are sponges, woollen cloth, henna, hides (chiefly of sheep and goat), and esparto grass, which is used in the manufacture of fine paper. All these articles are still exported in some quantity.

During the war the three most valuable products of Cyrenaica—viz., barley, esparto grass, and sponges—were entirely neglected; in 1917 the

exports of woollen cloth and goat skins were the only ones of real importance.

Other valuable products of Libya in the pre-war period were sheep, goats, camels, oxen, horses, skins, Sudanese leather cushions, wool, ivory, salt, cereals, ostrich feathers, butter, and dyewood. There is no doubt that the exports of sponges, esparto grass, barley, hides, wool, and live sheep and cattle may again assume considerable proportions.

To sum up the present commercial situation in Libya, a comparison of the import and export figures of the best year and the worst year during the period of Italian occupation is given, the official statistics for Tripolitana and Cyrenaica being combined: Imports in 1913 were valued at £1,349,000, and in 1917 at £2,332,000. Exports amounted to £188,000 in 1913, and £201,500 in 1917. In the latter year Libya was, therefore, in the unenviable position of having to import goods to almost twelve times the value of its exports.

The future development of Tripoli and Bengazi as principal cities—and of Derna, Tobruch, Misurata, Zavia, and Zuara as minor ports—remains dubious. The development of the great interior, one enormous stretch of Sahara Desert, appears impossible. Railways exist only along the coast, and those for but a few kilometres east and west from Tripoli and Bengazi. Roads there are practically none. To construct railways or build roads across the desert is also impracticable, as the sand shifts rapidly before the driving desert winds, and sandhills 200 feet high will move a quarter of a mile in a few hours. One railway has been constructed for a length of thirty kilometres due south from Tripoli to Suani Ben Adhem, but the trains run irregularly on account of the difficulty of keeping the line clear.

Only in the oases is agriculture possible, and any system of irrigation seems not feasible on account of the absolute flatness of terrain and the lack of watersheds or natural reservoirs of any sort. Water is to be found in the desert at 50 to 300 metres below the ground level, but desert wells can distribute their water over only a few score square metres of land.

The restoration of the caravan trade would do much to rehabilitate the commerce of Libya.

CORRESPONDENCE.

CARBORUNDUM.

I beg to draw your attention to a paragraph appearing on page 459 of the *Journal*, of May 28th, headed "Carborundum." The information contained bristles with inaccuracies, seeing that confusion has been made between the nature and properties of Carborundum and Corundum, which are two entirely different substances.

Reference is made to a Corundum plant at Niagara, it being obvious that the word Carborundum should have been used in this instance. To make it clear, I would point out that Carborundum has substantially a chemical formula CSi, being a Carbide of Silicon, whereas Corundum is substantially pure fused Alumina (Aluminium Oxide), having the formula Al_2O_3. Corundum is not, as stated, in any sense of the word related to the diamond, nor is it necessary for the preparation of synthetic gems such as sapphire, ruby, etc., that great pressure should be exerted, it being only necessary to provide sufficient heat to melt the alumina completely.

W. L. TURNER.

[After the paragraph had been put into type the blunders it contains were noticed, and instructions were given to the printer to distribute the type. Unfortunately these instructions were not carried out, and the paragraph was used to fill up a vacant space at the last moment before going to press, the printer assuming that it had been passed for press, which it certainly had not been.—ED.]

GENERAL NOTES.

DUTCH ROADS AND TRANSPORT EXHIBITION.—A Roads and Transport Exhibition will be held from 15th to 26th September, 1920, at Scheveningen, The Hague, in connection with the first Dutch Roads Congress. It has the support of the Netherlands Government, the organising Committee including Ministers of the Crown and leading Burgomasters, in addition to the chief technical experts. The development of road transport in Holland during the war years was very great, and from being a more or less negligible factor, it has now become a subject of considerable importance. Exhibits are to range from motor lorries and stone-crushers, tar sprayers and concrete mixers, to tyres and signposts, fuel and road-making material, and will also include such smaller accessories as maps and motor clothing. The industries concerned in this list are hardly represented at all in Holland itself. There are no lorry manufacturers, and only two makers of motor tyres. These facts illustrate the value of the opportunity open to British manufacturers of developing an entirely new market.

PROPOSED PORT FOR BHATKAL.—At the request of the Mysore Durbar steps are being taken to construct a harbour at Bhatkal, to provide a sea outlet for the State of Mysore. According to the Department of Overseas Trade, the formation of this harbour has been suggested for some time, and is one result of the commercial expansion of Mysore, which has been increasing for some years past. Schemes for the construction of the harbour have been submitted, including the provision of breakwaters to provide a safe approach during the period of the South-west Monsoon. Accommodation will be furnished for very large vessels, both in the inner and outer harbours.

MOTOR CARS IN NOVA SCOTIA.—The use of motor vehicles has been steadily increasing throughout the Province of Nova Scotia. During the period from 1st January to 10th September, 1919, licenses were issued for 9,770 motor cars and 177 motor cycles. Separate records are not kept of the issue of licenses to pleasure cars and to trucks, and it is therefore impossible to give the exact number of each of these classes of motor vehicles which may now be in use in the Province. Local dealers report the past season as having been a very satisfactory and successful one and state that the prospects are very favourable for heavy sales next season. One factor, according to the American Consul-General at Halifax, which has militated against a more extended use of motor vehicles has been the condition of the roads and highways in certain portions of the Province. Special attention is now being given to the question of better roads by the Provincial Government, and the sales of motor cars will unquestionably be favourably affected by the extensive work now being done in the way of road construction and maintenance. The popular demand is largely confined to fairly light cars of the less expensive makes. Importations from the United States are comparatively small, the majority of the cars sold being supplied by the Canadian branch factories of American concerns or by Canadian manufacturers. Most of the motor cycles sold here are, however, imported from the United States.

BEET SUGAR AND FRUIT-DRYING INDUSTRIES IN AUSTRALIA.—For the purpose of developing the beet-sugar industry Australia has inspected such factories in America, and intends incorporating the most up-to-date machinery for the treating of sugar beet into an Australian plant. The University of California has been asked to select a quantity of the best beet seed for the production of this sugar beet. The Victorian Government has also purchased from America a fruit-drying plant, by the use of which all danger of the Australian fruits being spoiled by rain in the process of drying is to be obviated.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 14 ... Transport, Institute of, at the Institution of Civil Engineer's, Great George-street, S.W., 5.30 p.m. Sir Joseph G. Broodbank, "To-day's Problems in Port Administration."

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. The Very Rev. Dean Inge, "Freedom and Discipline."

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. E. Cressy, "Great Engineering Adventures."

Faraday Society, at the Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. A. Fleck, and T. Wallace, "Conduction of Electricity through Fused Sodium Hydrate." 2. Dr. H. F. Haworth, "The Measurement of Electrolytic Resistance Using Alternating Currents." 3. Mr. J. L. Haughton, "The Measurement of Electrical Conductivity in Metals and Alloys at High Temperatures." 4. Messrs. N. V. S. Knibbs and H. Palfreeman, "The Theory of Electrochemical Chlorate and Perchlorate Formation." 5. Mr. J. B. Firth, "The Sorption of Iodine by Carbon." 6. Mr. F. H. Jeffery, "The Electrolysis of Solutions of Sodium Nitrate using a Copper Anode." 7. Dr. A. M. Williams, "The Pressure Variation of the Equilibrium Constant in Dilute Solution." 8. Miss N. Hosali, "Description of Models Illustrating Crystalline Form and Symmetry."

TUESDAY, JUNE 15...Grotius Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Lord Shaw, "The League of Nations."

Anthropological Institute, 50, Great Russell-street, W.C., 8.15 p.m. Professor F. G. Parsons, "Distribution of Hair and Eye Colour in the British Isles."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. The Secretary, "Report on the Additions to the Society's Menagerie during the month of May, 1920." 2. Professor J. E. Duerden, "Exhibition of, and Remark on, Ostrich Eggs." 3. Miss J. B. Proctor (a) "On a Collection of Tailless Batrachians from East Africa made by Mr. A. Loveridge in the Years 1914-1919"; (b) "On the Type-Specimen of *Rana holsti* Boulenger." 4. Mr. R. I. Pocock, "On the External and Cranial Characters of the European Badger (*Meles*) and the American Badger (*Taxidea*)." 5. Mr. R. J. Tillyard, "The Life History of the Dragonfly."

WEDNESDAY, JUNE 16...University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Professor A. J. Toynbee, "The Middle East—(Lecture III.)—Persian Empire and Hellenism (6th century B.C. to 6th century A.D.)."

Meteorological Society, at the Royal Astronomical Society, Burlington House, Piccadilly, W., 5 p.m. 1. Mr. W. H. Dines, "The Ether Differential Radiometer." 2. Professor S. Chapman and Mr. E. A. Milne, "The Composition, Ionization, and Viscosity of the Atmosphere at great Heights."

Electrical Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 6 p.m. Discussion on (a) the Paper read by Sir Dugald Clerk before the Royal Society of Arts, "Distribution of Heat, Light, and Motive Power by Gas and Electricity"; (b) the "Report on the Coal-gas and Electrical Supply Industries of the United Kingdom to the President of the Institution of Gas Engineers."

THURSDAY, JUNE 17...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. (Sir Joseph Banks' Centenary Meeting.) 1. The General Secretary, "Banks as a Traveller." 2. Dr. A. B. Rendle, "Banks as a Patron of Science." 3. Mr. J. Britten, "Banks as a Botanist."

Chemical Society, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Professor J. C. McLennan, "Helium."

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Mr. M. C. Jame, "Chinese Philosophy."

FRIDAY, JUNE 18... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir Valentine Chirol, "The Enduring Power of Hinduism." (Sir George Birdwood Memorial Lecture.)

Sanitary Engineers, Institution of (Summer meeting), Holborn Restaurant, W.C., 11.30 a.m. 1. The President, "The Institution and Its Future." 2. Mr. A. J. Martin, "Sanitary Socialism."
2.30 p.m. 1. Mr. T. Robertson, "Poured Concrete Construction." 2. Mr. G. W. Chilvers, "Health, Wealth, and Housing." 3. Mr. A. P. I. Cotterell, "A Glimpse at Domestic Engineering in some of the Eastern States of America."

Journal of the Royal Society of Arts.

No. 3,526. VOL. LXVIII.

FRIDAY, JUNE 18, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-sixth Annual General Meeting, for the purpose of receiving the Council's report and the Financial Statement for 1919, and also for the election of Officers and new Fellows, will be held, in accordance with the By-laws, on Wednesday, June 30th, at 4 p.m.

At the Annual General Meeting the Council will propose the following Resolution:—

1. That By-Law No. 56, relating to the annual subscription of members be altered and amended by the substitution of the word *Three* for the word *Two*.

2. That By-Law No. 59, relating to Life Compositions, be altered and amended by the substitution of the word *Thirty* for the word *Twenty*.

The By-Laws, as amended, will then read as follows:—

By-Law 56.—"The Annual Subscription of every member shall be *Three* guineas at least."

By-Law 59.—"Any member may commute or compound for all future payments, and become a member for Life, by payment of a sum of not less than *Thirty* guineas."

(By order of the Council),

GEORGE KENNETH MENZIES,
Secretary.

PROCEEDINGS OF THE SOCIETY.

TWENTIETH ORDINARY MEETING.

WEDNESDAY, MAY 12th; MR. HALSEY RICARDO, F.R.I.B.A., in the chair.

The paper read was—

ROLLS OF HONOUR.*

By GRAILY HEWITT, B.A., LL.B.

When I was asked to read a paper here, the subject suggested to me was War Memorials; and I was at once in a difficulty, for I could not define to myself what a war memorial may or may not be; and if I decided to speak only of such things as without a doubt *are* memorials, I must at once appear too limited or too technical to claim any general interest. The best I could do seemed to me to make some attempt to clear the air about the matter, and then, with apology for narrowness and technicality, to go on to deal with that form of memorial with which my craft, as a scribe, seems to be concerned, hoping you will neither think me presumptuous on the one hand, nor too dreadfully dry on the other.

For apparently many people seem to think, and I do not venture to disagree with them, that anything may be a war memorial, if you intend to make it so—as a public garden, or a bed in a hospital, or a swimming bath, or a scholarship. And indeed one feels that, in the highest sense, our England should be turned into one grand memorial, and that we should best commemorate the sacrifice and glory of our heroic dead if we could realise effectively that splendid dream of William Blake's: "I will not cease from mental strife, nor shall my sword rest in my hand, till we have built Jerusalem, in England's green and pleasant land." And every effort made towards that reconstruction we all have in our mouths, is a step towards this true memorial we desire. Yet we are well aware that, with too many of us, the chief concern is now the practical expostulation against the private injustices five years of war have produced in the adjustments of our daily lives. As if it must necessarily be always some one else's business to bear the

losses inflicted! As if submission (even to an injustice) may not be of the nature of memorial, and unselfishness now the true evidence that the lesson of our loved ones has not been disregarded! As if it were no come-down, after giving sons, brothers, husbands, to exclaim against a petrol tax! We dream we can efficiently record their unselfishness with a clock-tower or a drinking fountain, and proceed to ignore their example with calculations of the ways needed to put our own lives upon a pre-war basis.

The thing we have to commemorate is the glory of unselfishness. The true memorial is a higher standard of unselfishness. So only can we really record what the war amounts to. And unless we admit that, practically and permanently, we are all of us liable to fall, more or less, into the absurdity of that provincial councillor, who was reported in a local paper to have proposed at a parish meeting that a suitable memorial to his fallen fellow parishioners would be the substitution for the uncomfortable pews in his church, of the convenient tip-up seats one finds in the picture palaces. But after all, is his extravagance essentially different from those who design memorial chapels? What is the purpose of a memorial chapel? Shall we have prayers for our dead in it? Shall we even have regular services there, and read out their names lest they be forgotten? Shall we do more than make, at best, a beautiful bit of architecture, open it to visitors, and call it a war memorial? Or a stained-glass window? It is not a memorial without an explanation. Even a stone cross in a village is not a memorial of this war unless it has the identification of the years upon it, without which it remains the general symbol of Christianity. There seems hardly anything we may make, which can of itself be a memorial —without this sort of identification, that is, some reference by inscription. One may except statues, which can but be memorials of one, or a few, or a pillar like Nelson's Column, which is at once and unmistakeably self-explanatory. But who inevitably calls to mind our deliverance in 1815 when passing over Waterloo Bridge? We connect that with the London and South-Western Railway Co. It is next to impossible to imagine any new symbol of the grandeur of self-sacrifice, independent of some inscriptional explanation added to it. Indeed, the dictionary defines a memorial as "Something, as a monument or an inscription designed or adapted to preserve the memory of a person or an event deemed worthy of honour"—leaving one to exercise one's imagination as best one may.

So that while anything may be a worthy memorial if made with true motive, it were a bold man who should come here and speak of methods of construction; or even of the adjustment of suitable inscriptions to such a multitude of objects as may at once be called to mind. I asked, therefore, to be allowed to deal with such inscriptions only, as of themselves compose the entire memorial, that is, the making of records of men's names and deeds, individually or collectively, as by reference to a certain place or a certain regiment; since such records are simply memorials, and not objects of utility or convenience as well—what are called Rolls of Honour. Even so the subject is wide enough, for rolls of honours may be executed in stone or marble, brass or wood, vellum or paper, and may be of any size or shape for that matter.

Their essentials are a "legend" and a list, the legend setting forth of what the list consists, followed by the list. The legend is really most important, and yet it is usually little considered. Committees, formed for the purpose of making local memorials, too often find such difficulty in establishing full and satisfactory lists, that when these are complete no energy is left for consideration of suitable heading; and they content themselves with such words as "Men who fell in the Great War," with possibly the addition of a worn text to be added above or below; when immediately there is introduced a weary sense of stale emotion, the perfunctoriness of a conventional sentimentalism. There are now a dozen or more catchwords connected with these things, to which repetition has brought something like disgust. And one of the few fine phrases the war has given us—Kipling's "Who dies if England lives!"—has been worn to shreds in a newspaper. We seem to lack sense of the elevated use of words. Wisely, the Whitehall Cenotaph said nothing but "the glorious dead." But this very reticence was an acknowledgement of this inability, this literary or inscriptional ineptitude. It has at least avoided the possibility of staleness, it can never become undignified.

The local committee, however, has usually no diffidence in flinging a quotation on to stone or brass. We have all seen "Greater love hath no man than this, that a man lay down his life for his friends." Of the brave boys who are gone, is there one who would be ready to endorse the comparison this implies? Is it quite fair to the dead to overdo and add the tinge of exaggeration's insincerity to our honour? For however true this may be of some of them, there is this general implication of comparison with the typical self-sacrifice which imports that "little more" than truth.

But of most it is not true, and they made no such pretence. They risked their lives, and gave their lives, without any such assumption of altruism. One of our poor words, one of those self-conscious confessions of our verbal deficiency, perhaps expresses it. They did it because it was "the thing," because, as more than one of them has well said, there was nothing else to do. Their enlistment was, in fact, the loyal and ready expression of the social instinct we have achieved. And this has no doubt been fastened on by those others of us who have inscribed Horace's old tag of "Dulce et decorum est pro patria mori," without pausing to consider that the half of this at least is quite untrue. Of the million dead and missing, is there one who found the business of death "dulce"? There is now, moreover, added the suggestion of our society slang, that we consider it "sweet of them."

Besides which, most of us feel that a foreign tongue has no place in records so national. Our own tongue must do. It is strange that Shakespeare gives no help, and that so much that might be quotable from our Bible involves that comparison I have alluded to. Yet there are, of course, many verses applicable; and one of them is St. Paul's phrase "As dying, and behold we live," a curious precedent for the Kipling line I mentioned just now. Of our later writers, here and there may one pick a phrase, and a favourite one is Rupert Brooke's "Now God be thanked who has matched us with His hour." And one most beautiful verse is that of Laurence Binyon:—

They shall not grow old, as we that are left grow old:
Age shall not weary them, nor the years condemn.
At the going down of the sun, and in the morning
We will remember them.

But of all the poetry I have searched for help, there seems to me nothing comparable to those lines of Tennyson, from his ode on the death of the Duke of Wellington:—

A people's voice! we are a people yet.
Tho' all men else their nobler dreams forget,
Confused by brainless mobs and lawless Powers;
Thank Him who isled us here, and roughly set
His Britain in blown seas and storming showers,
We have a voice, with which to pay the debt
Of boundless love and reverence and regret
To those great men who fought, and kept it ours.

On the whole, however, it seems safest to omit such quotations—at least, if the inscription is very public, not in a book—and to confine the legend to a severe and literal statement of fact, leaving the fact to speak to those who can listen to facts, and avoiding all catchphrases such as "Great War," "European War," "World War," "King and Country," and, worst of all, "Supreme sacrifice." I have even met "shed their blood," and that dreadful "did their bit" formally inscribed. There seem so many to whom English, just English, is dry pedantry, to whom nothing makes an emotional appeal unless it appear in guise of slang or the petticoats of sentimentality.

I usually suggest something like this—even if I am not asked: "Of the parish of Blank in the county of Blank These gave their lives serving the King in the years of Our Lord 1914–1919," which seems to me accurate, entirely sufficient and conveying every implication necessary. When the roll is of *all* who served, and not the dead only, I put "served" instead of "gave their lives serving," and then distinguish the dead by gilding their names in the list, or by putting a gold cross before their names. Note that the word "these" conveniently includes both sexes. And I attach much importance to those words "served the King" or "serving the King." Occasionally a republican-minded client has absurdly objected to them, and has asked them to be altered to "served their country," which is a much weaker expression, meaning simply "helped to preserve it from its enemies." Serving the King implies this and much more than this, it implies serving the cause of Truth, Right and Honour. There is a grand traditional significance in the words. And our form of Government being what it is, they are the correct general words for employment in His Majesty's Naval, Military, and now Aerial Forces, and involve no politics whatever. The King is symbol and embodiment, and I confess personally to finding a noble ring in the words I would not go without.

Again, I constantly see the years mentioned as 1914–1919 or 18 or 20 as may be. This seems to me too colloquial for use for our purpose. After all our era is not worldwide; and there is a literal dignity in acknowledging this. So "Year of Grace," "A.D.," or "Year of our Lord" seems necessary. Moreover, by so stating it, we verbally connect the sacrifices recorded with that typical sacrifice, but modestly and indirectly. Here again the client has sometimes to be persuaded. For the heathen-minded is apt to consider he lives in 1920, or "the year 1920," without admitting that neither wording is accurate enough for a thing so formal as a memorial inscription. It is, in fact, an abbreviation. The legend above suggested seems appropriately sufficient in the case of a panel. But if the form of the memorial is that of a Book, the wording of its title, its preface or introduction, may well be considerably more than this. In the case of a school or other old foundation, it seems handsome to introduce at least some of the old school prayers, which the boys have grown up with and learnt to live by (or at least

have learnt to love as part of the dear old place and its ways). And in books much local or explanatory matter may also be introduced. Perhaps even on a panel one might add the words "at home and abroad" (though the words I suggest really include every field). And sometimes the theatres of war may need mention as Gallipoli, Palestine, Mesopotamia, France or Flanders, or indeed particular battles or actions.

And then the names. Is it unfair to say that the Church had a chance here, and has not taken it? In how few of our country parishes did the parson at once set about keeping record of his flock! In how many places is not the memorial even now held up for want of a reliable list! Of course it was difficult; the black sheep, the enemies of church-going were among the first to go, the least missed; and we all know the difficulty of defining the word "parishioner," even in parishes with a fairly stable population. Yet if the Church had done this thing well she might have retained some of that grip upon our lives she complains she has lost and is losing. This was a practical and valuable way of asserting her claim, that not one of these fell to the ground without a father's knowledge. It seems to have been nobody's business in particular.

Such lists as we make are, moreover, nearly always lists of surnames. It would be almost impossible to hope for a list with full Christian names. Outside our families we are all known by initials. Initials do not look well in a roll of honour. They have a dry perfunctory look. Men are baptised by name, not initial, and a roll of honour seems to demand a similar fulness. If, however, we must have initials at least we can put them in front of the names and not after, as is done so often by those who would sacrifice all to alphabetical *appearance*. I say *appearance*, because the alphabetical order is not altered by putting the initials first. Brown, F. L., Jones, G. J., and Robinson, W. M., are impossibly "indexed." And besides the names, in most cases people seem anxious to have the ranks and regiments mentioned to which the men belonged. And one usually falls in with the suggestion, since at once a decorative columnar arrangement can be adopted and an orderly plan formed. Yet one may wonder, perhaps, whether this little piece of the end of a life-history is better worth recording than much that went before. If is of little comparative importance whether a man was a Queen's Westminster or a Post Office Rifle. It might be much to know whether he gave up banking or baking, or linen-draping to lay down his life in Flanders. In one list I have made the names of the men's mothers and fathers were given. And this struck me as fine and just that their relatives should so claim the honour of record in company. Details of place and date of death seem naturally desirable, where known, and mention of actions, and battles, and wounds, and, of course, the initials of distinctions won, as V.C., D.S.O., M.C., D.S.M., M.M., etc. These may well be added in gold immediately after the man's name.

The fulness and amount of detail to be given usually settle whether an arrangement in columns or by paragraphs be preferable. When rank, regiment, name, and date of death are the particulars supplied, the arrangement by column may well be adopted, since an orderliness and decorative appearance is at once provided, especially if one or two of the columns be written in colour, leaving black for the names themselves. If, however, many details besides these are desired with each individual a small paragraph may well be allotted. Or, again, if nothing but the actual names are needed, and these are not numerous, a fine effect may be made with the extreme simplicity of writing them continuously as a single paragraph, and so making a decorative panel of the massed names. In this case the individual name is lost sight of in the general effect—a thing one's first thought rejects and one's second may well approve. A paragraph so designed and rendered entirely in gold lettering on vellum would make a fine panel.

Most usually, when the names are numerous and arranged by columns with rank and regiment, I have found it clarify the work to put them thus:—

Rank.	Name.	Regiment.
Blue.	Black.	Red.

reversing the colours for the Navy. And if this roll is one of service and not of the dead, the names of the living can be rendered in black, and those of the dead in gold. No note of explanation seems to me to be required. By this plan the names are brought down the centre of the page or panel, as may be, and may well be written larger than all else.

But in what order shall the names be set? In most cases an alphabetical order seems preferred, as if any other arrangement made for invidious preferences. Yet, why not? Indeed, before conscription came a roll of service seemed very rightly to be arranged in order of enlistment. Unfortunately this order was too rarely known to be available, and after conscription

it conveys no necessary information. By date of death is another possible arrangement, where the roll is of the dead only.

Or, again, the arrangement may be by reference to regiment. This is, however, awkward except where the list is a very large one, and the names fairly distributed among a number of regiments, or except where, in a parish, the men have all belonged to one or two regiments. And this is rarely the case. In the South African Roll for Capetown Cathedral this arrangement was adopted, the names were marshalled under regimental headings and under subheadings of rank, officers by seniority, non-commissioned officers and men alphabetically; and all regiments and names were treated equally, the order being that of the Army List. But in that case there were 22,000 names and more, and the whole of the British Army, I think, was represented. No other arrangement was possible.

As to the names of regiments, unless these be given in full (which is most inconvenient with the limited space usually available), there is always a difficulty. For most regiments have alternative and supplementary titles, or an official title and a popular one, and there seems to be no principle to go by. Indeed, the King's Librarian has informed me that there is no consistent usage, so that most rolls adopt the popular names, and the scribe must inform himself as to these. For instance, the Queen's Bays do not care to be called the 2nd Dragoon Guards nor the Royal Scots Greys, the 2nd Dragoons, nor the Black Watch the Royal Highlanders. Yet the three latter are all the correct short official titles, and the only names given in the scrolls for the next-of-kin now being issued by the War Office. So also the East Kent Regiment is more popularly known as The Buffs, the Royal West Surrey Regiment as the Queen's, the West Riding Regiment as the Duke of Wellington's, and so on; and one might imagine the horror of a sergeant of the London Scottish at being described as of the 14th County of London Rifles, or of a Queen's Westminster or a Post Office Rifle at 16th County of London or 8th City of London being considered sufficient. With some regiments the War Office is even now making alteration. The Welsh Regiment and the Welsh Fusiliers may now spell their name with a "c"; but the Welsh Guards will retain the "s." The Notts and Derby Regiment are, I believe, about to become officially, as well as popularly, the Sherwood Foresters.

A further point is the abbreviation and contraction of regimental names. We have written in initials during the war, and there was, no doubt, good reason. But on a roll of honour these initials look merely slipshod; and even contractions are only advisable to keep the arrangement fairly uniform. One must contract the Argyll and Sutherland Highlanders somewhat, as also the Oxfordshire and Buckinghamshire Light Infantry. But R.A.M.C., K.R.R.C., K.O.Y.L.I., R.G.A., R.F.A., R.E., and so on, seem on a record too much like slang. Official contractions are given in the Army List, but I am afraid they have not a very literary look.

As to the forms of rolls of honour, these seem to be the panel form (where the names are not too numerous, or space allows of several side by side) and the book form.

Panels may be single, or made up into diptychs or triptychs, or set in frames in a line of several. And they are no doubt usually chosen that all the names may be equally visible on one sight line or thereabouts. A book either shows but one opening, or, if accessible for turning, is liable to dirt and damage. Yet I feel that as a record it is preferable, and, where guarded by a case, will easily outlast all others. Indeed, a parchment book, kept dry and well used, is practically indestructible. There are many of us, too, who do not particularly value seeing the names as in a shop window. We want to know that they are there preserved for all time. That is primarily what such a record is for—not for exhibition. Strolling in Canterbury Cathedral lately I looked at the various military memorials in the nave, containing the lists of names of men killed in former wars. To their own generation they meant somewhat; but to the stranger these monumental panels looked dreary enough. They are not decorative, mostly hideous, with black rims, stupid carved cannons, and presiding goddesses. Are we going to fill our churches with such things by the hundred now?

Is not a book a handsomer thing? Not only can it be made more decorative in itself, but it will not disturb the architecture of the place nor obtrude itself to the offence of anyone. It is ever more interesting than memorials which display all their contents at a glance, with its suggestion of treasure gradually unfolded to the reader, and not worn away by time, or the very care which would preserve stone or brass by the necessary cleaning of them. And, further, a book would offer a delightful opportunity for usage—if ecclesiastical authority could be persuaded to countenance it. On some anniversary, as of Peace

Day, or oftener, in the years to come, the book could be read out from the pulpit to the congregation. It would seem to me that such a reading would be more likely to keep alive the record of the names than will the plastering of walls with lists which will shortly be no more than glanced at, as those in Canterbury were by myself. There is precedent for such usage in what is called the Bidding Prayer, enjoined by the fifty-fifth Canon of the Anglican Church in 1603, and still used occasionally, I believe, in some cathedrals and churches, wherein mention is made of benefactors passed away. Are not these dead heroes our greatest benefactors ?

Or, again, where the names are numerous, as in many large towns and cities, these may be divided by 365 or 12, and so many as result set to an opening or page of the book; and each day or month a page could be turned so that throughout the year the book would display every man's name in turn, and thus become a new sort of calendar of saints. And possibly the names could be ordered by reference to date of death, even yet more appropriately. Indeed, I have made one so. Such books could be kept on lecterns under glass against the wall or a pillar of the church.

Stone or marble lists are only suitable where the names are but few; otherwise these tend to be cut so small, as not to be cut well. A monument with ill-cut letters is at once a failure. And to me *incised* cutting is always preferable. The Imperial Roman inscriptions were always incised, and, indeed, most also of the Renaissance inscriptions, though the raised letter with its stronger effects is established by that time too firmly to be thrown overboard. This was not originally a stone letter but a metal letter (a metal worker's or die-cutter's letter), and was adopted for stone work in a mistaken care for conspicuousness, and then established by lovers of ostentation.

And in incised cutting nothing is so fine, because so well adapted for the tool, that is the chisel, as the Roman capital alphabet, those majestic majuscules evolved by true craftsmanship, and developed by sympathetic refinement —all impertinent experiments in turn eliminated as in other natural processes—through the ages.

But with brass one may be permitted to question their advisability. Brass is not beautiful in itself as fine stone or marble is beautiful. It has no grain or texture, no warmth and variety of colour, no translucency as of marble or alabaster. The beauty must be given by the writing and by the contrast of the colour of this, either the writing or the ground being blackened or coloured. And one always recognises in fine mediæval brasses that this effect was valued—what one calls "fine *colour*." And to get this an alphabet is necessary which shall not have the refined elegancies of the Roman inscriptional majuscule. The best examples, being those of Gothic times, are of course examples of black-letter. And black-letter, as is implied in its very name, was an alphabet of heavy strokes. Hence the ease of the noble effect gained with it. But nowadays one may hardly use black-letter without danger of illegibility in writing letters which do not belong to our modern life and literary conventions.

I venture to suggest that this double difficulty may be overcome by employing the Roman minuscules, with great thickness of stroke and packed very tightly. Used thus they will give great beauty of "colour," almost as effectively as the Gothic letters, and yet remain legible. Moreover, I have found that the graver prefers the rounded forms so provided to the angularity of the chisel-cut shapes, which are properly fitted only for stone work; which is only to say that one needs to consult the particular material one is working upon.

Italics seem to me unsuited for inscription, except, perhaps, on slate, where the difficulty of the material seems to suggest a fine, that is a thin, line. They are too essentially pen-forms, and thin pen-forms at that, not needed for stone, for which the Roman minuscule suffices, where a minuscule is really advisable, and quite out of place on brass, where thick work is wanted, which is contrary to their nature.

Then there are painted letters—that is, brush-made letters. Now, as a penman I have a sort of jealous dislike of painted letters. Letters are not painted things. The brush seems never to have evolved a real alphabet of its own in which its technique might have appropriately modified traditional form to its peculiar requirement. At best it but makes, and always has made, imitations of the more direct appearance of pen strokes, and its proper use would seem to be limited to those places, as walls or roofs and ceilings, where a pen cannot work. But where, as with most rolls of honour, the thing is a panel however big, and not necessarily written *in situ*, and so upright, there seems no occasion for brushwork, except on such surfaces as a pen cannot manage. Justification for using such surfaces would be very exceptional.

A pen can be made of any size for reasonable requirement, of reed or cane for large work.

The so-called "parcel pens" of commercial use give true pen-forms, which seem preferable to the laboured imitation of the brush. A pen certainly will not work with oil colour, but there are waterproof inks which are very serviceable, and only when the panel's surface needs to be an oil-painted surface, to be in keeping with the rest of the memorial, does a real necessity for the brush arise. Otherwise, where vellum is not used, a very good surface for the pen's performance can be made of a gesso well sized. On this the pen will work almost as well as on skin, and the gain to the writing is very marked. With this there is none of the almost inseparable feebleness, the faking and retouching of letters which the brush seems hardly able to avoid. It may be argued that this depends only upon the skill of the painter. But the penman knows it is not so, and that one might as well try to carve wood with a hat-pin or paint with a palette-knife as think to reproduce the derivatives of the Roman alphabet with aught but the tools which evolved them. It might very well have been otherwise. The Far East has brush-made writing, and one can, perhaps, imagine that the brush might have rendered our own alphabet with a developed technique of its own, applied perceptively and, in process of time, magnificently. Only this has not happened. For pen work, then, on a large scale gesso panels may be used, for one has to remember that vellum and parchment skins are not available larger than four feet by three at most. And these are best stretched—after one's work—upon stretchers as for painters' canvases. Vellum—that is, calf skin—is best, of course, but now very expensive. Parchment (that is, the split skin of sheep, lamb, or goat) does very well for smaller work. Until lately I found the unsplit skin of sheep (known in the trade as "grained forel") very useful; but now it is all used up for boots and shoes, I am told.

All skins have a "quality" no gesso, cardboard, or painted surface can approach. There is all the difference between transparent and opaque complexion. It is a constant wonder to me that artists do not make their black-and-white drawings on parchment for the advantage of this "quality." But skin has the further advantage that it has no grain to trip the pen. Moreover, if kept fairly dry, it is practically imperishable. The mediæval parchment books will easily outlast their contemporary architecture. Most modern churches, however, especially now, are apt to be damp at times. In such cases the framed rolls should be well protected by waterproof cloth backing, and the frame, where possible, kept from the wall with little corks at the corners. And, in particular, the glass in front should be kept from the surface of the skin by means of a mount (hidden, if need be, by the rebate of the frame), this mount raising the glass about half an inch from the skin, that cockling may not be encouraged by condensations on the glass, or raised gold used in the decoration of the MS. touched by it.

As to the decoration, I hardly venture to make suggestions. There are so many things I do not want. I do not want flags; flags are meant to wave in the wind, not to be draped and flattened to a design. I do not want cannon, nor khaki-clad figures, nor feminine angels pointing upwards, nor goddesses of Peace pointing downwards, nor Britannias mourning, nor any of the pomps and circumstance of funerals. The recent show of war memorials at the Royal Academy evidenced a great deal too much gloom. These records are lists of heroes. If we have to commemorate the loss of them we have also the gladness and glory to commemorate that Britain has bred so many thousand such; and another rather important thing, here so generally disregarded: that they won the war, that they are not only heroes, but victors. Theoretically I want them all to be written in gold on purple. And since, as a matter of fact, that particular combination is somewhat ineffective, I want at least colour as well as fine letter forms; and all such symbolism as our oak and holly and ivy and rose and hawthorn, and, of course, the bay can import, woven into wreaths and garlands or the very bodies of prominent letters, as in the true illuminator's manner, especially those calendars in the Psalters of old. And of course, wherever possible, heraldry. To accompany lettering there is no decoration so happy and sympathetic. Heraldry *is* almost lettering, the language of signs for words. It is unfortunate, however, that the regimental badges are mostly so poorly designed, and the designs by use now so stereotyped, that their introduction is rather a hindrance than a help. But even without designed or woven decoration we may have the help of colour. For colour not only decorates, but, as a matter of fact, also clarifies the arrangement (as I hope the few examples I have brought sufficiently suggest). And besides colour, gold. It is rather remarkable that, in spite of the centuries' denunciations of riches, we still gild the cross upon St. Paul's, and can separate all sordidness from our admiration for this beauti-

ful thing, and pay our highest honour with it. It is still *the* symbol of value.

Just a word of warning of very practical sort. To those who intend to set a roll of service in a church a "faculty" is needed, at least for anything of the nature of a fixture, and this "faculty" will not be granted if the roll contains the names of those still living. Why this should be so, Heaven knows. It means that our bishops hesitate to create a precedent even in times unprecedented. It has not been done before. Only if you are dead can your name be set in a church, and then you cannot, as a rule, be prayed for. And another still more practical. This craft of formal penmanship, though fostered latterly in our technical schools, largely under the enlightened influence of the London County Council, has not hitherto offered such an outlet as a means of livelihood as to encourage very many to adopt it. There has been no market for it. But now the occasion has come—and a market. But that occasion will not last. When these records are completed the market will probably be done. It therefore seems reasonable to suggest that rather than call for an increase in the number of scribes at once, who will in a year or two be thrown out of work, we were better advised to spread the work over a longer period and establish the few in more lasting occupation. At present there are some forty-odd scribes working upon the memorial scrolls I have mentioned for the War Office. These scrolls will probably be completed this year, and scribes trained and competent will be available for and needing other similar work. Is it too much to ask that committees of memorial records should not be in a hurry to have their works completed? After all, these things are not intended temporarily to aid a passing fashion, but to last. And to be in a hurry over them may not only mean that they may be hustled and ill-done, when we need them done with as much care and practised experience as may be, but also surely implies that we already feel ourselves in danger of forgetting. Are we going to forget these names unless we scrawl them up at once somehow?

DISCUSSION.

THE CHAIRMAN (Mr. Halsey Ricardo, F.R.I.B.A.) said the paper was a very pregnant one, and probably contained some things which were provocative.

Replying to some questions, the author said he knew several churches where there were lists of men who had served in the Army, but probably they were not fixtures, and so it had been possible to avoid the Faculty in that way. He did not know what was the correct way of putting the dates with regard to the war. The War Office at one time gave 1918, the date of the Armistice, as correct, and then January, 1920, as the official date. There was still, however, the Turkish matter going on, and that might complicate things. If it were the case only of the dead, the date of the Roll could be fixed by the date of the death of the last man on it.

MR. W. MORRIS said those who were responsible for advising Committees on erecting memorials were generally hard put to it to find sufficient money adequately to do the work, and that appeared to be the principal trouble in connection with recording the list of men who had served, apart from those who had died. If the 6,000,000, or whatever it was, were all recorded, the cost would be so tremendous that the quality of the work would naturally suffer. A parish that had to report 100 names of men who had died might possibly do something worthy with the money they were able to raise, whereas if they had to increase the names tenfold it would mean very indifferent work for the money at their disposal. Possibly the reason why a Faculty could not be obtained for the names of men who had served being placed in churches was that it was found safer to lay down a rule that only those who had died should be recorded, and also many of those who had served objected to their names being on the list, as they did not want to see them when they went to church. He would like to know whether the author had heard of the new idea that Mr. Wratten had been working on in connection with modern heraldry; he had very cleverly introduced all that could be said in tokens of heraldry—for instance, the badge of the regiment would be the crest so far as it could be applied, the years of service would be shown by chevrons, the rank would be for a captain three stars, and the colours of the regiment would be introduced. The College of Arms, however, had promptly turned the scheme down. The idea appeared to bring heraldry within the reach of commoners, and would cause people to take a very laudable pride in the history of their sons.

MR. W. H. GODFREY said there was no doubt that the essence of a memorial was both the beauty of expression and the method of putting it in the form of lettering. He had been much interested in the reference to heraldry. He had been invited to discuss the subject at the Art Workers' Guild shortly. The matter was put forward in the *Connoisseur* about twelve months ago, and was purely a notion for combining in one emblem the service record of each man, whether he was a member of the Army, Navy, or Air Force. For some time he had been trying to discover how to put the whole military service of one individual in one emblem, and then it occurred to him that the ribbons and badges a man wore were so

essential that, apart altogether from the beauty and importance of heraldry as heraldry, the same principle might be used that the heralds of the thirteenth century used in forming an emblem that would give succinctly the record of a man's service. He did not for a moment wish the idea to be put in competition with heraldry; the word "heraldry" was simply used because of the mechanical method of combining the badges and colours, and had no other heraldic significance. Where there was a particularly beautiful roll required, as, for instance, in the case of a college or private association, where full particulars of a man's service could be obtained, it was possible to make a beautiful symbol.

Mr. C. Harrison Townsend was glad that the author had widened his scope and considered the setting of the inscription, beginning at the very beginning of things. After all a memorial was an inscription, and everyone had some idea of the embellishment and setting of that inscription. A great debt of gratitude was owing to the author for so beautifully emphasising the importance of the inscription in a memorial.

The Chairman, in moving a vote of thanks to the author, thought the thing that had to be considered, besides the making of a memorial, was the retaining of the memorial in one's memory. He had been very much touched by Mr. Hewitt's notion of turning over the various pages of a book once a week or once a month, so that the names should be brought to remembrance. There was a natural tendency at the present moment to make great efforts, both pecuniary and enthusiastic, to raise memorials, and there would be a tendency by-and-by, when the wave of emotion was slacking, to think that we had "done our bit," and were not called upon to do anything more, and it would be a great pity if the memorials were allowed to get shabby or neglected. Something could be done, he thought, in the way of having periodical memorial services of a very simple kind; they need not necessarily be ecclesiastical at all, but such an arrangement as a meeting, say, on August Bank Holiday of the villagers at the memorial, bringing flowers and holding a simple service. It would have the advantage of ensuring that the monument was kept in decent condition and that the lettering was kept clear. It was really important to insist on the maintenance of the memorial after it had been made. With regard to heraldry, it was a kind of shorthand. It began in days when people could not read, and was very effective in showing who was who and how he came about and what his rank was. There was an immense amount of living heraldry to-day, as, for instance, the blazers of schools and football and cricket clubs, the colour of omnibuses, and the colour of pillar-boxes. Within certain bounds it was possible to play with heraldry and use it for definite purposes, and there was no doubt that it was a means of introducing a great deal of interest and colour and history which otherwise would take pages perhaps to explain. No one could have listened to the paper without being extremely interested and illuminated, because problems were dealt with which had hardly come into prominence yet, and to have an authority like Mr. Hewitt dealing with the matter was exceedingly instructive.

The motion having been carried, Mr. Graily Hewitt briefly returned thanks, and the meeting terminated.

THE CLOCK INDUSTRY OF NAGOYA.

In Nagoya are produced about 75 per cent. of the clocks manufactured in Japan, most of the remainder being made in Tokio. The industry grew out of the attempt of a mechanically-gifted native of the near-by town of Okazaki to duplicate a clock brought to Japan some years previously by one of the officials despatched by the Government to the International Exhibition held in Vienna in 1873. In 1886, after a year of constant effort, this man succeeded in making two clocks that could be regulated fairly well and kept good time. In the following year a clock factory was established in Nagoya under the name of the Jiseisha, but it was not until 1890 that its products were put on the market. In 1891 three more factories were opened, and at the present time there are nineteen factories in Nagoya, with 1,200 employees, devoted to the manufacture of various kinds of wall, mantel, and alarm clocks. By 1894 the number of clocks produced was sufficient to supply domestic demands and to permit of the export of a number to Korea and China. The following years witnessed a widespread distribution of Japanese clocks throughout the Orient, and they are now exported to all parts of the world.

According to a report by the United States Consul at Nagoya, it appears that before the war England and Switzerland almost entirely supplied the iron and steel materials from which the clocks were made. After the outbreak of the war, however, when European supplies ceased, limited quantities of wires and springs were received from the United States. This supply subsequently failing, the clock makers were obliged to turn to domestic sources, and by the time the war was half over the Imperial Iron Works at Yawata, Kiushiu, succeeded in making steel springs and wires of fair quality for use in the manufacture of second-grade clocks, which partially supplied the urgent demand. The same firm expected by April this year to be able to make tinplate and springs of good quality, but the clock makers are not sanguine that this expectation will be realised. Upon the cessation of hostilities they endeavoured to place orders with the firms in England and Switzerland with whom they did business before the war, but were disappointed owing to the difficulties experienced by these firms in resuming work, which made it impossible to guarantee definite delivery dates in filling orders.

The outbreak of the war naturally terminated

the export of German clocks to the Far East, and the suspension of this competition brought more orders than could be filled by the Japanese makers, handicapped as they were by the lack of proper materials. This is evidenced by the marked falling off in production during the year ended March 30th, 1917, as compared with the previous year, although at the same time prices rose about 50 per cent. In this connection it is interesting to note that the average price in the year ended March 30th, 1916, was 4*s.* 4*d.*, as compared with 10*s.* 3*d.* in 1919. While the increased cost of labour and materials is in part responsible for the higher prices, they are undoubtedly largely due to reduced competition.

The Nagoya customs figures show that while in May, 1919, almost double the number of clocks were exported to China, as compared with the corresponding month of 1918, in June and July only about 40 per cent. were exported, as compared with the same period of the previous year.

The clocks of different varieties and grades sell at wholesale for from 30 yen (yen = 2*s.* ½*d.* at par) to 100 yen per dozen, the cheaper varieties being sent to China and the South Seas. The dealers anticipate additional good markets for the low-priced clocks in South America and Africa. The higher-grade varieties are now finding a sale in Europe and America.

The following figures were obtained from the Aichi Clock Makers' Guild, showing production and distribution of their products during the four years ended March 30th, 1916–1919 :—

Year ending March 30th.	Domestic use.		Exports.		Total.	
	Number.	Value in U.S. dollars.	Number.	Value in U.S. dollars.	Number.	Value in U.S. dollars.
1916	71,313	110,423	273,278	249,104	344,591	359,527
1917	27,309	45,227	185,901	311,113	213,210	356,340
1918	34,606	73,967	271,183	458,701	251,789	532,668
1919	29,891	83,044	285,645	702,979	315,536	786,023

The destination of the exported clocks during the year ended March 30th, 1919, was as follows ;—

Destination.	Number.	Value.	Destination.	Number.	Value.
		U.S. dollars.			U.S. dollars.
China	183,888	510,046	Peru	421	1,074
Kwantung Province	42,045	100,258	Other South American countries	516	597
Hong-Kong	30,925	47,907	Egypt	1,079	1,488
Straits Settlements	6,932	11,026	South Africa	498	537
British India	2,601	5,707	Vladivostock	181	468

French India	583	1,332			
Philippine Islands	3,758	7,780			
Great Britain	1,767	1,908	Total	285,645	702,979

MINERAL WEALTH OF FINLAND.

A close study of the mineral wealth of Finland is being made by the Finnish Geological Commission, whose objects are: (1) to examine the extent, value, and utilisation of known mineral sources, and (2) to search for new deposits. Surveys have already been made regarding materials such as calcareous rocks, brick clay, whetstone material, bog ore, rare metals, and to some extent granites. A survey will next be made of iron ore deposits, and estimates of quantity and quality obtained. This will include also research into methods of refinement which will be done in a special laboratory.

According to a report by the United States Diplomatic Commissioner at Helsingfors, the following are the most important of the older iron fields in southern Finland: Pitkaranta, on Lake Ladoga, which contains large quantities of magnetic iron ore, mixed somewhat with sulphides; Kelivaara, an adjacent iron field with similar ore; Valimaki, in the parish of Sordavala, with ore which must be crushed and made white hot before use, but which yields particularly good pig iron: and Jussaro, a large part of which lies under the sea, where the low percentage of metal, in places so far worked, renders it still uncertain whether it can be utilised after the preliminary crushing and separation.

Finland's iron-ore possibilities, however, lie chiefly in Lapland, which is known to be rich in iron, but even here there is no probability of finding rich ores of the kind found at Gellivaara and Kiirunavara on the Swedish side. There are no corresponding geological formations in Finland, and the Swedish formations do not stretch eastward over the frontier, but southward, parallel to it, toward the Gulf of Bothnia. On the other hand, there are on both sides of the frontier fairly extensive areas of another kind of magnetic iron ore. Most of those on the Finnish side, at Juvakaisenmaa and Kolari, have long been known; but it is owing chiefly to the geological researches of Dr. V. Tanner, the Finnish geologist, that those on the Swedish side have been brought to light. It is thought that the deposits at Juvakaisenmaa are sufficiently large and rich in metal to be worth working if transportation facilities were

better. The ore, however, is not of the best grade.

There are also iron deposits on the Finnish side at Kittila in the Porkonen-Pantavaara field. These have long been known. There is no doubt that there are larger quantities of ore, but much of it is of such a kind as to necessitate crushing and heating before use. It is not yet known whether there is ore that can be used directly. The ore seems to be of much the same kind as that in Sydvaranger, on the Norwegian side of the frontier, where work for a considerable time has been carried on rather largely but with varying success.

The copper deposits at Orijarvi and Pitkaranta have long been known; and although their metal content is low they cannot be regarded as exhausted. During recent years considerable deposits of copper pyrites and sulphur ore have been discovered in the so-called "Kalevian" rock strata, which runs from Lake Ladoga towards the Ulea marshes and thence towards the north. The most important of these are the copper deposits at Outokumpu, which in size and metal content deserve to be described as the Finnish Falun. (Falun is the Swedish copper district.)

There are also sulphur-ore deposits at Otravaara in Eno and at Tipasjarvi in Sotkamo, the former having been known for some time without, however, attracting much attention. The war-time increase in the value of sulphur rendered the working of these deposits worth while, and from these and probable new finds it is hoped to obtain not only copper but sulphur far beyond domestic requirements.

Zinc blende has been found here and there although it has not played any economic *rôle*. Lead ore also is known, and may possibly suffice in the future both for Finland's requirements and for export.

In addition to their economic importance, the above-mentioned finds of pyritic ores have an indirect significance. Owing to them it has been shown that the "Kalevian" strata were more deeply penetrated by metal solutions in remote ages than had previously been thought. The prospects of discovering more ore of a similar sort are therefore very promising.

Most of the auriferous veins in Lapland that have been worked experimentally have shown a disappointingly low average content. The circumstances of the first find of rock ore at Karkelas, however, and the fact that coarse gold is found in fairly large quantities in insignificant river sources, suggest that there exist richer pockets in the rock. It is upon such a supposition that the Geological Commission has under consideration measures for further investigations.

Upon first experiments most experts believe there is a zone of gold veins under a covering "iron hood" of decomposed sulphur ore, but it is known that these coverings consist of crumbled, rusty masses whose origin had nothing to do with sulphur ore.

Gold also occurs in southern Finland in the Orijarvi district. Under the direction of Swedish experts investigations are now in progress as to possibilities there.

Platinum is occasionally mentioned as one of Finland's assets, but the unimportant grains that have been found in the rivers of Lapland do not justify any hope of platinum washing.

PRODUCTION OF PYRETHRUM FLOWERS IN JAPAN.

The peculiar properties of pyrethrum flowers, a variety of chrysanthemum (*Chrysanthemum parthenium*), which, when dried, is a deadly poison to insects, while at the same time harmless to higher animal life, including man, have made these flowers a very valuable insecticide.

Like a great many other industries in Japan, the production of pyrethrum flowers and the manufacture of insect powder greatly increased during the war. Prior to 1914 the chief sources of supply were Dalmatia, Persia, and some parts of south-eastern Europe; but during the past four years practically the world's supply has been produced in Japan. The first marked increase in production was in 1916, when the total weight of dried flowers reached 4,368,850 lb., as against 2,190,365 lb. in 1915. Before this time there was a gradual increase in production, but until the war stopped production in other countries this increase was not marked.

The acreage under production and the quantity of dried flowers produced during 1914-19 were as follows:—

	Acres.	lb.
1914 . . .	2,760	2,135,700
1915 . . .	2,800	2,190,365
1916 . . .	6,920	4,368,850
1917 . . .	10,712	6,845,208
1918 . . .	10,474*	7,720,000
1919 . . .	3,809*	2,479,680

It will be noted from the above figures that the production for the years 1917 and 1918 was very large, but that there was a great falling off in 1919.

According to a report from the American Consulate at Kobe, the centre of the pyrethrum-flower production in Japan is in the Okayama and Wakayama Kens (Prefectures) in the Kobe district, practically the entire exports being shipped from the port of Kobe.

The average size of Japanese farms is about $2\frac{1}{2}$ acres, and the average field devoted to pyrethrum flowers measures about one-third of an acre. These fields are uplands (as distinguished from paddy fields) and, owing to their small size, as well as to the limited amount of capital on which the farmers work, are entirely prepared and crop harvested by hand. The seed is usually sown broadcast, which, of course, necessitates very little cultivation, but it is also sometimes sown with

* Acreage for 1918 and 1919 is based upon the average production in 1915, 1916 and 1917, no actual statistics being available.

drills and cultivated. The average production per acre is about 651 lb.

The pyrethrum plant is a biennial, dying out at the end of the second year, and its production prohibits the use of land for other purposes during the same year. On the other hand, grasses raised for straw braids are produced in addition to a food crop, so that the return per acre planted in grasses is greater than that for pyrethrum flowers. For this reason, as well as because of the shortage of foodstuffs in Japan, many farmers formerly producing pyrethrum are turning to straw for braids.

The following statistics show the exports of dried flowers and insect powders for the six years from 1913 to 1918:—

	Flowers. lb.	Powder. lb.
1913	350,225	210,012
1914	819,612	256,566
1915	2,058,090	309,664
1916	1,811,564	557,123
1917	3,330,672	671,218
1918	3,223,845	815,050

In the year 1913 the largest foreign purchaser of the Japanese flowers was Great Britain, which took 184,930 lb., while China purchased the largest amount of insect powder, 77,084 lb. During that year the exportation to the United States amounted to only 30,376 lb. of flowers and 16,027 lb. of powder. In 1918, however, the United States was by far the largest purchaser of flowers, exports to that country amounting to 2,721,993 lb., or 84 per cent. of the total exportation. China, however, is still the leading purchaser of insect powders, exports to that country amounting to 206,682 lb. in 1918, while the export of powder to the United States amounted to but 120,949 lb., or about 14 per cent. of the total exportation.

It is estimated that the decrease in acreage caused by failure to replant will cause a decrease in the 1920 production of dried flowers to approximately 1,411,200 lb., which is less than the production in 1913.

THE OLIVE AND OLIVE-OIL INDUSTRIES IN ALGERIA.

Olive growing, it is believed, is destined to become one of the most certain sources of wealth in Algeria. The value of the trees under cultivation rises annually. The principal regions engaged are in the Department of Oran, and in that mountainous country just east of Algiers, known as Kabylia. The number of ungrafted olive trees in Algeria in the year 1912 (the latest year for which statistics of this kind are available) was 5,680,654, of which 4,097,114 belonged to natives, and 1,583,540 to Europeans.

The number of grafted trees was 7,764,568; Europeans owned 3,093,159 of these, and natives 4,671,349. In addition there are a great many wild-olive trees, some on lands belonging to the different communes, most of the rest on the public domain; these yield, for the most part, a small fruit. In fact, even the cultivated product in Algeria is still small, but, by selection and grafting, some improvement has been effected. The Forestry Service of the Government-General has had this work in hand for some time. Between the years 1911 and 1916, 32,737 graftings were made, as follows: In 1911, 7,984; 1912, 14,251; 1913, 441; 1914, 2,909; 1915, 3,096; 1916, 4,156.

Cultivation, however, is not intensive, especially on the part of the natives, as is indicated by the comparison of the number of grafted and non-grafted trees owned by Europeans and by natives. Irrigation, too, plays practically no part in the work. But, on the other hand, the ravages of the "olive fly" are said to be comparatively negligible: the Entomological Branch of the Zoological Service of the Government-General of Algeria stated in its report for 1917 that this insect was increasing but that active measures were being taken for its suppression.

Local consumption of both green and black olives is so large as to necessitate importation; the finer grades coming principally from France, while Spain supplies a considerable quantity of black olives. A large part of the Algerian crop is used in the production of olive oil, especially by the native Arabs and Kabyles, who owned and operated about 93 per cent. of the 5,123 olive-oil mills producing in 1912. According to a report by the United States Vice-Consul at Algiers, the machinery, especially in the native mills, is very primitive, and the operators are careless. This results in considerable waste, estimated to be at least 10 per cent. Some of the European mills, however, are equipped with modern appliances—such as vacuum machines for removing foreign matter from the oil.

The lack of discrimination in selecting the fruit to be used increases the naturally strong taste of the Algerian product, and necessitates its mixture with other kinds to render it palatable to Europeans, though the natives use it very much as butter is used, and employ it almost exclusively in cooking. In 1911 the yield of oil from the native presses was placed at 179,419 hectolitres (3,947,218 Imperial gallons), and in 1912 some 197,921 hectolitres (4,354,262 Imperial gallons). Only a small portion of the hulls and pulp are utilised through treatment with carbon disulphide. Since 1912 three factories have been operating in Algeria for this purpose, with a combined capacity of 20,000 metric tons per annum.

A partial remedy for the waste in the olive-oil industry is being found in co-operative mills, and also in the growing tendency of the natives to sell their product to Europeans, whose factories are better equipped. The extension of good roads will also be of benefit.

Algerian olive oil has been largely shipped to France. Tunisia has also taken a considerable amount, and treated or mixed it with its own product.

TUNGSTEN MINING IN CHINA.

The discovery of tungsten in China occurred in recent years, the deposits being found in the southern provinces, below the 30th degree of north latitude. At the present time, with a few exceptions, the mines are not owned by any private companies or by the Government, but any one may employ men to work a mine.

From a report by the United States Vice-Consul at Shanghai, it appears that the principal districts in which tungsten is found are in the Provinces of Hunan (southern part), in Hangchow and its vicinity; Kiangsi (southern part), in the Lungnanhsien, Tinnan, Sinfenghsien, Nankanghsien, and Taiyu districts; and Kwangtung (eastern part), in the Wuwha, Hingninghsien, Kaiyung, Heifung, Lukfung, and Wailia districts (northern part), in the Namyung, Lokchong, Chihing, and Chukiang districts. The districts mentioned above are only those in which operations are now being carried on, there being other large areas in which tungsten deposits are found, in the southern parts of the Provinces of Hunan and Kiangsi and the north-eastern part of Kwangtung, which have not as yet been opened.

Chinese tungsten, in the form of wolframite, occurs either as sand or pebbles in the streams or in small veins in the granitic rocks. The former deposits are sometimes accompanied by cassiterite or magnetite, or both, usually mixed with quartz sands, the latter in the form of veins ranging in thickness from a fraction of an inch to 2 or 3 inches. Although both kinds of deposits are found in many widely scattered regions, they are never found in large quantities in any particular area. For this reason, and also because this industry is of very recent origin in China, no modern systematic methods have been inaugurated to explore this field.

Rakes, toms, and pans are used for washing the stream ores, while in the case of vein ores, hand hammers, drills, and sometimes black powder are used for extracting the valuable contents of the ore. With the exception of a few places in Hunan and Kwangtung, nearly all the mining is carried on by farmers, who work during their spare time after their farming labour is completed. But during the early part of 1918 the industry had grown to such an extent that many of the farmers suspended their farm work and devoted themselves entirely to tungsten mining.

The concentrates offered on the market are rather impure, and usually have to be reconcentrated for export purposes. For this purpose a few native, as well as foreign companies have sprung up, each having a concentrating plant of some sort. One concern has a fairly well-equipped plant, containing shaking screens, jigs, rocking tables, and round revolving tables for concentrating its own ores and those collected from mining centres; and it is in a position to produce concentrates of 67–72 per cent. WO_3 with about 5 per cent. of manganese, and containing but a small amount of impurities, such as copper or tin.

The farmers take their concentrates to the local market where they dispose of them to local dealers at the best prices obtainable. The local dealers, in turn, sell them to licensed collectors from the ports. The port dealer has to pay a tax to the Government, and, after shipping the concentrates to his own port, he is under obligation to export them within a certain period, usually three months. If he fails to do this he is obliged to get another licence for the same ore or forfeit the ore to the Government.

The total exports of tungsten ore in 1918 amounted to 10,365 tons (of 2,000 lb.), but the total production during the year far exceeded this figure, there being large quantities left in the mining districts which could not be sold owing to the cessation of hostilities in Europe. The working of the deposits continued, nevertheless, until February, 1919, when it was found that the returns would not cover the cost of labour.

Up to August, 1919, tungsten ore was wholly an export product, as China had no way of utilising the ore. A plan was formulated for establishing a plant at Hankow for making ferro-tungsten, but the scheme was postponed on account of the inactivity of the tungsten market. It is understood that there is a small smelting plant at Dalny, which, however, is still in an experimental stage.

It is difficult, adds the United States Vice-Consul, even to estimate approximately the quantities of future production for any definite length of time, as, thus far, no authoritative survey has been made of this field in China. It is estimated that all the mines in the above-mentioned districts are capable of equalling their production during the year 1918 for more than ten years. Future shipments abroad will be governed entirely by the demands of the American and European markets.

NOTES ON BOOKS.

THROUGH DESERTS AND OASES OF CENTRAL ASIA. By Miss Ella Sykes and Brigadier-General Sir Percy Sykes, K.C.I.E., C.B., C.M.G. London: Macmillan & Co., Ltd. 21s. net.

In 1915 the two authors of this book travelled to Kashgar, the capital of Chinese Turkestan, where Sir Percy Sykes was to act as Consul General during the absence on leave of Sir George Macartney. Miss Sykes writes an interesting account of their journey and of their stay in Turkestan. As she has already shown in her book, "Through Persia on a Side-Saddle," she has a keen eye for a country and for the manners and customs of its inhabitants, and she has the power of conveying her impressions in a lively and readable style. The interest of this work is very considerable. The country is little known to Europeans; a European woman in many districts had never been seen before. Miss Sykes was therefore an object of at least as great curiosity to the natives as they were to her, and she has much that is amusing to tell of her encounters with them.

One of the most interesting parts of the volume is the spirited account given by Miss Sykes of the journey over "The Roof of the World." She was the first Englishwoman to cross the Katta Dawan Pass, and it was a feat that she is justly proud of. The difficulties were very great. The immense height of the pass (over 15,000 feet) causes many people to suffer from mountain sickness; the country is barren, bleak, and inhospitable, and the climate is such that in a single day the travellers suffered severely from snowstorms and from scorching heat. Only the merest track was visible in many parts, and that often led by rough and dangerous ledges overhanging frightful precipices where a slip meant certain death. For the greater part of the trail the travellers rode on ponies, but when the track became too steep they took to yaks, which in spite of their clumsy appearance contrived to keep their feet under a rider or a load of baggage where any other animal must have come to grief. Some excellent photographs give a good idea of the dangers and desolation of the Pamirs, and also of the various types of people with whom the travellers came in contact.

The second part of the book, dealing with the geography, history, customs, sport and other subjects, is the work of Sir Percy Sykes. This contains a great deal of fresh information about a little known land, which will be of special interest to the anthropologist. Here it must suffice to refer to Sir Percy's encounters with that remarkable creature, the *Ovis poli*. When Marco Polo returned from his travels, he told tales of wild sheep on the Pamirs of enormous size, "whose horns are good six palms in length." Nobody believed him. How could such creatures pick up a living in a country where vegetation was of the scantiest? However, time has justified Marco Polo in this, as in most of his stories. Sir Percy Sykes shot several of these sheep, and he tells us: "The height at the shoulders exceeds 12 hands, and the weight may be about 22 stone. The length of the horns is enormous, one specimen, believed to be the longest on record, measuring 6 feet 3 inches! Marco's 'six palms' may perhaps be the equivalent of 5 feet; so that his estimate is in no way exaggerated." It is satisfactory that just, if tardy, reparation has been made to the memory of the great traveller by calling this animal *Ovis poli*, Polo's sheep.

This work may be warmly commended to all who love books of travel. It should possess a special interest for readers of the *Journal*, for both the authors are Fellows of the Society, and both have read papers here.

GENERAL NOTE.

THE RUBBER GROWERS' ASSOCIATION PRIZES.—The Rubber Growers' Association (Incorporated) offer the following awards for ideas and suggestions for extending the present uses or for encouraging new uses of rubber: One prize of £1,000: three prizes of £500 each: ten prizes of £100 each: a sum not exceeding £1,500 to be divided amongst the remaining Competitors whose suggestions are considered to be of value, according to the relative value of their suggestions, but so that no competitor will receive more than £100. Suggestions must be practical and likely to increase the demand for the raw material. Ideas will be welcomed for the application in new directions of existing processes, methods or manufactures, or for improvements or new processes which will facilitate or cheapen the production of rubber goods. Competent judges (technical and otherwise) will be appointed to investigate and adjudicate upon the suggestions received. All enquiries in connection with the Competition (other than the Competitive Suggestions) should be addressed to The Rubber Growers' Association (Dept. C.), 38, Eastcheap, London, E.C. 3.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 21...Geographical Society, 135, New Bond-street, W., 8.30 p.m. Major L. F. I. Athill, "Through South-West Abyssinia to the Nile."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m.

TUESDAY, JUNE 22...Aeronautical Society, Central Hall, Westminster, 8.30 p.m. (Wilbur Wright Lecture.) Commander J. C. Hunsaker, "Naval Architecture in Aeronautics."

East India Association, 7A, Tothill-street, Westminster, 4.30 p.m. Mr. P. J. Hartog, "The Work of the Calcutta University Commission."

Pottery and Glass Trades Benevolent Institution, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Annual Meeting.

WEDNESDAY, JUNE 23...Electrical Engineers, Institution of, Wireless Sectional Meeting, at Institution of Mechanical Engineers, Storey's-gate, S.W., 6 p.m. Mr. B. S. Gossling, "The Development of Thermionic Valves for Naval Uses."

Nurse's Pension Fund, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m.

Geological Society, Burlington House, W., 5.30 p.m. Mr. O. Holtedahl, "The Scandinavian Mountain Problem."

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Professor A. J. Toynbee, "Islam and the Caliphate (6th to 11th century A.D.)."

THURSDAY, JUNE 24...Incorporated Society of Trained Masseuses, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6 p.m. Sir Charles Ballance, "Healing Process in Nerves."

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Sir E. Denison Ross, "Gujarat in the time of Akbar."

Medicine, Royal Society of (Laryngology Section), Summer Congress.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m.

FRIDAY, JUNE 25...Incorporated Society of Trained Masseuses, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 6.30 p.m. Miss M. Bond, "Some Factors influencing Nutrition and Growth."

Medicine, Royal Society of (Laryngology Section), Summer Congress.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Journal of the Royal Society of Arts.

No. 3,527. VOL. LXVIII.

FRIDAY, JUNE 25, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

FINANCIAL STATEMENT FOR 1919.

The following statement is published in this week's *Journal* in accordance with Sec. 40 of the Society's By-laws :—

INCOME AND EXPENDITURE ACCOUNT,

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Sixty-sixth Annual General Meeting, for the purpose of receiving the Council's report and the Financial Statement for 1919, and also for the election of Officers and new Fellows, will be held, in accordance with the By-laws, on Wednesday, June 30th, at 4 p.m.

At the Annual General Meeting the Council will propose the following Resolution:—

1. That By-Law No. 56, relating to the annual subscription of members be altered and amended by the substitution of the word *Three* for the word *Two*.

2. That By-Law No. 59, relating to Life Compositions, be altered and amended by the substitution of the word *Thirty* for the word *Twenty*.

The By-Laws, as amended, will then read as follows:—

By-Law 56.—"The Annual Subscription of every member shall be *Three* guineas at least."

By-Law 59.—"Any member may commute or compound for all future payments, and become a member for Life, by payment of a sum of not less than *Thirty* guineas."

(By order of the Council),

GEORGE KENNETH MENZIES,
Secretary.

INDIAN SECTION.

FRIDAY, JUNE 18th; THE RIGHT HON. LORD MESTON, K.C.S.I., LL.D., in the chair. The first Sir George Birdwood Memorial Lecture on "The Enduring Power of Hinduism" was delivered by SIR VALENTINE CHIROL.

The lecture will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

WEDNESDAY, MAY 19th; MR. ALAN A. CAMPBELL SWINTON, F.R.S., Vice-President of the Society, in the chair.

The paper read was—

THE COMMERCIAL APPLICATION OF ELECTRICAL OSMOSIS.

By JOHN SOMERVILLE HIGHFIELD, M.Inst.C.E., M.I.E.E.; W. R. ORMANDY, D.Sc.; and D. NORTHALL-LAURIE, F.I.C.

The study of matter in the colloidal state is one of the first importance and is of surpassing

interest. The problems resolve themselves into the scheming of methods of studying the rate of movement and the causes of movement of particles of very small size often approaching

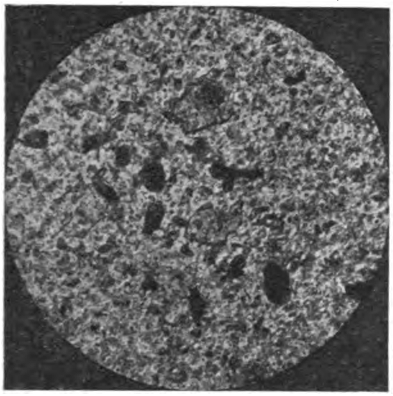

FIG. 1.
CHINA CLAY FROM CORNWALL, AFTER ORDINARY TREATMENT.
Magnified 150 times.

molecular dimensions. The forces causing movement are molecular, chemical, and electrical, added to the force of gravitation, and the movements may take place in any medium, but usually in water. The importance of the subject is apparent when it is realised that many of the largest trades and manufactures depend on the use and proper treatment of matter in the colloidal state. Agriculture depends on a suitable colloidal state of the soil, tanning of leather on the introduction into the cells of matter in colloidal form. The glue and gelatine industry deals with colloidal matter. The dyeing of fabrics consists largely in introducing finely divided material into fibrous matter. Again, by a scientific study of their slimes the efficiency of the recovery of metals can be increased. Papermakers deal with matter in a colloidal state. Trades so diverse as dairy production and paint manufacture are equally concerned in the treatment of colloidal matter.

The terms colloid or matter in a colloidal state, true solution and suspension, are not easy of simple definition. For the purpose of the immediate subject, matter in a colloidal state or a colloid means matter in so fine a state of division that it tends, under favourable circumstances, where coalescence does not readily take place, to remain for some hours in suspension.

The term Osmosis, or Osmose, appears to have been first used by Graham about 1854; it may have been derived from the Greek word Osmos, meaning "pushing," and the terms Exosmosis and Endosmosis, used by Dutrotchet about 1800, refer to a pushing outwards or inwards, osmosis being a general pushing such as the diffusion of liquids through a diaphragm. The importance of the phenomenon has long been recognised as it is one consistently occurring in living bodies, both animal and vegetable. The first record appears to be by Nollet (1700–1770) as a result of experiments with water and alcohol through a bladder. Dutrotchet investigated the subject, and his work resulted in numerous applications in methods of dialysis by Graham. Graham insisted that the phenomenon was molecular, and that it is due to the raising of sap in trees against gravity.

Graham, in 1861, found that when a weak solution of sodium silicate was poured into excess of hydrochloric acid no precipitate was formed, whereas, if the sodium silicate solution was strong, a gelatinous precipitate of silica was obtained.

He found that by placing this clear solution in a small dish made of parchment, and floating it in water the sodium chloride produced by the reaction passed through the pores of the parchment paper, and, by frequent changes of the surrounding water, could be completely re-

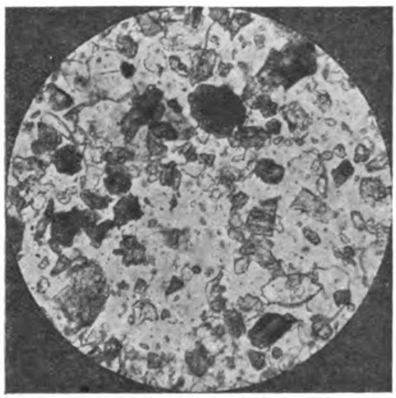

FIG. 2.
LARGE PARTICLES OF MICA, SILICA AND ROULEAUX CONSISTING PROBABLY OF KAOLINITE REMOVED BY THE PROCESS.
Magnified 150 times.

moved, leaving inside the dish the silicic acid, thus proving that it was not an ordinary solution.

Graham called the silicic acid when in this

condition a *Colloid*, whereas he termed the salts and other similar bodies that passed through parchment *Crystalloids*, and the separation of one from another *Dialysis*.

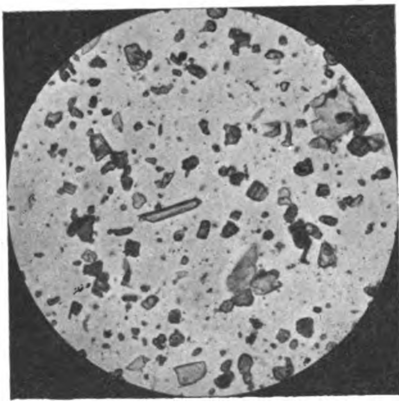

FIG. 3.
SMALLER PARTICLES OF IMPURITIES REMOVED IN THE OSMOSIS MACHINE.
Magnified 150 times.

These original definitions have been extended and amplified. A colloidal solution is termed a *Sol*, and, if water is the liquid in which it is contained, the sol is known as a *Hydrosol*; if alcohol, an *Alcosol*, or generally an *Organsol* if the medium is some organic liquid.

The colloidal substance is termed the *Disperse Phase*, whereas the medium in which it is dispersed is termed the *Disperse Medium*. Most materials, including metals, sulphides, oxides and salts can exist in the colloidal state. Natural substances occurring in very small particles such as Ball clay, China clay, and the various types of Fire clay, can be brought into the colloidal condition by suitable means, and most naturally occurring compounds as Emery, Quartz or Steatite, and the artificial abrasives, Carborundum and Alundum, can be rendered colloidal by sufficiently fine grinding.

The existence of a material present in the colloidal state in a so-called solution can be demonstrated in various ways. For instance, when the colloidal particles are extremely minute their presence as particles can be shown either by dropping upon filter paper when the colloidal matter will remain as a stain in the centre, the disperse medium, in this case water, spreading out round it; or by passing a powerful beam of light through the liquid when the particles will cause the path of the beam to become visible, and the light reflected from the particles to be polarised. This experiment was first shown by Tyndal, and is known as the Tyndal effect.

Electrical Properties of Colloidal Solutions.—Picton and Linden found that matter in colloidal suspension, when subjected to direct current of upwards of sixty volts between platinum electrodes, tended after a time to collect either around the anode or cathode, leaving a clear space around the cathode or anode respectively.

They investigated this phenomenon and found it to be of general occurrence. It is known as Electrical Osmose or Cataphoresis, and the polarity of the particles depends not only upon the constitution of the particles but on the nature and quantity of electrolytes present, and also upon the composition of the disperse medium in which they are suspended as the disperse phase. Thus, silicic acid is charged positively when in water, and negatively when in turpentine.

Generally, the continual suspension of a colloid in the disperse medium is possible only when the colloidal particle retains an electrical charge. The particles possessing the charges of the same sign, either positive or negative, repel each other, and so cannot coalesce or coagulate together.

They can be made to coalesce by subjecting them to an electric field by means of immersed electrodes, when they are attracted to the pole of sign opposite to their charge, and are so discharged; this is the industrial method used in the purification of clay.

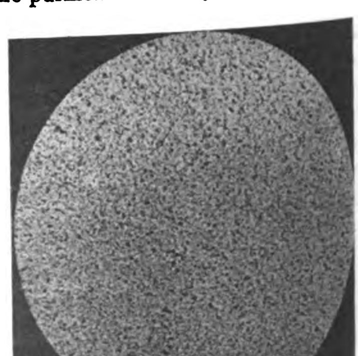

FIG. 4.
THE OSMOSED PRODUCT.
Magnified 150 times.

They can be made to coalesce by adding to the liquid an equal number of colloidal particles of opposite charge, when the two sets of particles mutually discharge one another. As

an example, the addition to a colloidal suspension of arsenic sulphide of a colloidal suspension of a basic material, such as ferric hydrate, causes the precipitation of the two colloids.

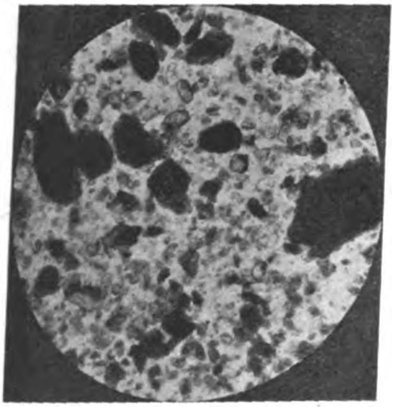

FIG. 5.
STAFFORDSHIRE MARL, AFTER WEATHERING.
Magnified 150 times.

The quantity of one colloid required completely to precipitate another colloid of opposite charge varies with the composition of the precipitating colloid. Biltz gives the following figures: 1·4 m.g. of gold is completely precipitated by:—

4 m.g. of cerium oxide;
3 m.g. of ferric oxide;
2·5 m.g. of thorium oxide;
1·6 m.g. of zirconium oxide;
0·3 m.g. of chronic oxide;
0·1 to 0·2 m.g. of alumina.

The order of power of precipitation varies with the substance to be precipitated, and depends probably upon the absorption capacity of the material.

Another method of bringing about the coagulation of peptised particles is to add to the suspension a small quantity of a salt which in solution is subject to electrolytic dissociation. If the peptised particles carry an electronegative charge, then the added electrolyte must be electro-positive; thus, bodies which are peptised by an alkali are precipitated by an acid.

The deposition of the fine silt and mud carried down by rivers when the stream encounters the salt of the sea is, no doubt, due to the flocculation of the dispersed particles by the salt electrolyte.

In order that the phenomenon of electrical osmose can be shown, it is necessary first that the colloidal material in suspension should be broken up by giving each minute particle an electrical charge, thus preventing coalescence, that is to say the suspension should be peptised.

Various materials can be peptised, each requiring different peptising agents: thus, gelatine is peptised by hot and not by cold water; gums by cold water; mastics in alcohol by large quantities of water; metals by fused metallic salts; hydrous oxides by caustic alkali.

The special application of these principles, to which we wish particularly to refer, is the purification of clay and similar materials. The commercial application of these phenomena to the purification of clay is due to the late Count Schwerin. He showed that the addition of small traces of alkali to a suspension of clay in water resulted in the suspension becoming highly mobile, the clay particles remaining for a long time in suspension, the pyrites, mica, free silica, and other impurities which are not peptised, tending to fall through the suspension.

Count Schwerin, in his patent specification, points out that bodies in suspension which tend to move to the cathode, require an electrolyte of an acid character to be employed to bring about dispersion or peptisation, but that bodies which tend to move to the anode require electrolytes of an alkaline character. It is further of interest to note that the original inventor not only shows that the addition of suitable electrolytes can be used to peptise the

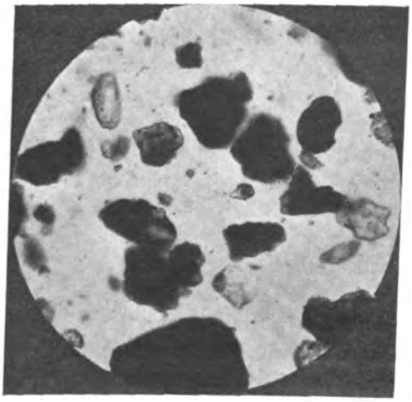

FIG. 6.
IMPURITIES CONSISTING OF PYRITES AND SAND REMOVED.
Magnified 150 times.

main matter in suspension, to bring about increased fluidity with the object of allowing foreign matter to separate out by subsidence, but he also points out that if one substance is

present in varying degrees of fineness, it is possible by the utilisation of the same principles to bring about a separation of the fine particles from the coarse ones.

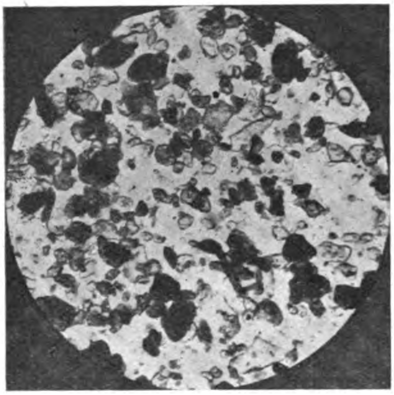

FIG. 7.
FINER IMPURITIES REMOVED BY THE MACHINE.
Magnified 150 times.

Coalescence of the peptised particles in a clay slip can be produced by discharging the particles by the addition of acid to the suspension; the clay then settles in a gummy flocculated mass, carrying with it the fine impurities as previously explained. The action of the acid and alkali on the slip can be illustrated by reversing the method and allowing a thin stream of neutral clay slip to flow into a vessel containing on the one hand acid, and on the other alkali; in the first, the clay particles fall in a continuous solid stream and settle quickly; in the second, the clay particles spread out broadly and settle very slowly.

There are many disadvantages to the flocculation of the clay by coagulating with electrolytes; certain fine impurities remain in suspension and are carried down with the flocculated clay, so that only partial purification is attained. The physical state of the clay is entirely altered, and the clay is left in a form difficult to collect and dry. For these reasons, the electrical method of purification was developed.

If, in the prepared suspension, two electrodes are immersed, and a difference of electrical potential be established between them, the clay particles move to the anode, where they discharge themselves and adhere as a coagulated mass, and the water is driven to the cathode, leaving the clay in a semi-dry state attached to the anode. The fine particles of silica, mica, pyrites, and other impurities, either migrate to the cathode or are washed away by the water stream moving to the cathode.

This is an example of using a direct electrical pressure to produce coalescence in a peptised suspension.

The effect of the practical application of the process on clay is to remove particles of mica, silica, pyrites, and felspar, and to leave the clay substance in a satisfactory state for final drying. The effectiveness of the purification is illustrated by reference to photo-micrographs, Figs. 1-11.

It is, perhaps, allowable at this stage to indicate some of the directions in which the osmotic treatment of clay leads to advantages, having a direct and practical bearing upon industry. It is not realised sufficiently that the melting point of pure clay substance is higher than that of any admixture of clay substance with silica, although it is commonly known that the other ingredients generally present in mined clay, such as pyrites, mica, felspar, and the like, are very active in reducing the melting point. The more finely divided the silica and other impurities, the more intense the action in bringing about the softening of the clay substance at high temperatures, for the fine state of division brings about a great area of active contact surface. It is this fine material that cannot be removed by settling, and which the Osmosis process successfully eliminates.

The sintering or vitrifying temperature of a

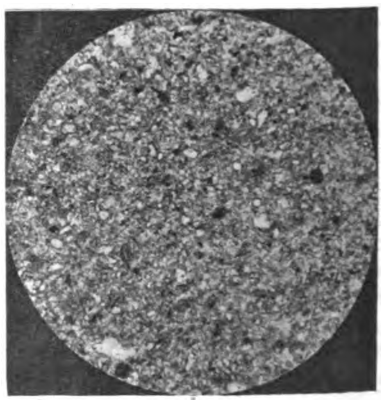

FIG. 8.
OSMOSED PRODUCT CONSISTING ALMOST WHOLLY OF CLAY PARTICLES.
Magnified 150 times.

clay may be taken to be the temperature at which the rapid contraction of the clay in firing ceases; above this point little contraction occurs. Sintering takes place in osmosed clays

at lower temperatures than in the raw clays; consequently, goods made with osmosed clay can be finished at lower temperatures, resulting in a saving of fuel. The reduction of the

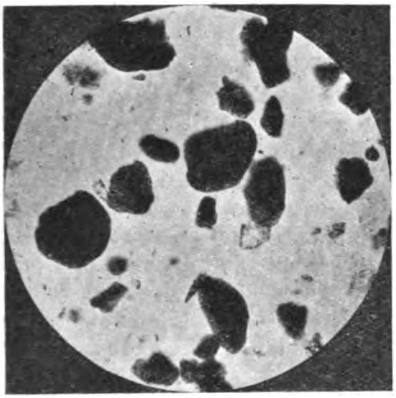

Fig. 9.
Impurities removed from a fine quality Ball Clay.
Magnified 150 times.

sintering temperature, together with the higher melting-point, enables articles to be made that show little further contraction after burning. The amount of the reduction of the sintering temperature varies for different clays; it is as much as 300° C. for low-grade clays, and much less for high-grade clays. Bricks made from some clays, after osmosing, are better burnt at 1,100° C. than from the raw clay at 1,300° C.

Many alluvial red-burning clays cannot be fired to vitrification because, before vitrification temperature is reached, the clay commences to blow. Many such clays, after the osmosis treatment, have a margin of from 100° to 200° C. between the vitrifying temperature and the temperature at which decomposition starts. This enables vitrified bricks and vitrified roofing tiles to be made from a product which, without treatment, could not be used for such purpose.

In the manufacture of porcelain and earthenware, osmosed clays yield whiter bodies or bodies freer from specks and stains. Osmosed fireclays are entirely free from pyrites, and goods made therefrom are not subject to green stains when glazed.

By the use of fine osmosed materials, chemical porcelain has been produced of the highest quality, the body being made of pure kaolin only, which, owing to the fineness of the particles, completely vitrifies; the locking of the glaze to the body by the fine sillimanite crystals, which form on firing and penetrate the glaze, is shown in the photo-micrograph, Fig. 12.

The form given to the apparatus for the commercial purification of clay consists of a tank of suitable form, containing at the lower part two paddles, which serve to keep the suspension in agitation, and which direct it in a stream through the numerous small spaces in the cathode fixed immediately above, surrounding the lower half of the anode. The anode consists of a metal cylinder, revolving at a speed of about one revolution in three minutes, at a distance of about three-quarters of an inch from the cathode. A scraper removes the clay from the anode, whence it falls down a shute clear of the machine. The fresh clay suspension is fed into the lower part of the container, and the water effluent returned to be mixed with fresh clay. A machine with a cylinder, two feet diameter and five feet long, produces about 1,000 tons of pure clay per annum.

The manner in which the machine acts towards the clay slip is as follows:—

The clay in suspension, in passing through the laminated or perforated cathode, becomes negatively charged and is immediately attracted to the anode cylinder, the water being driven towards the cathode. There is thus obtained a dry layer of clay on the anode cylinder and a watery zone of clay suspension round the cathode. Fresh clay entering the machine encounters the watery zone on its passage to

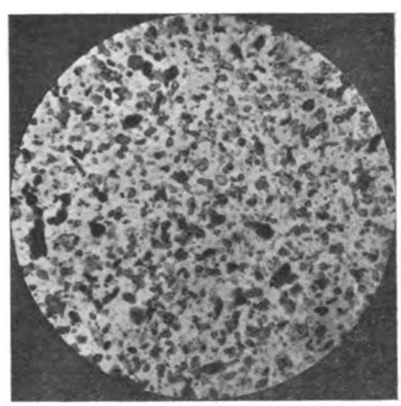

Fig. 10.
Fine Impurities removed by the Osmosis Machine.
Magnified 150 times.

the anode, in which zone the electro-osmotically indifferent particles such as pyrites, mica, and quartz, become freed from the clay, and are washed away with the effluent from the

machine. The effluent with these particles also contains some clay. It is carried to a settling tank where the impurities quickly settle out, and thence to a blunger, or other

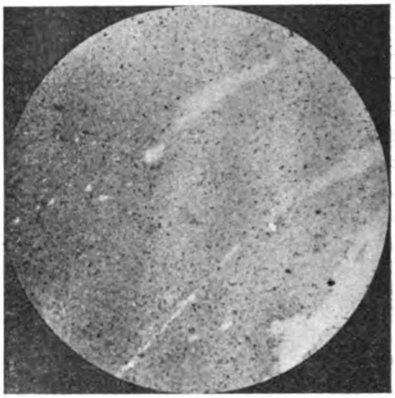

FIG. 11.
THE OSMOSED PRODUCT.
Magnified 150 times.

mixing machine, where it takes up fresh clay and returns again to the machine through one or more settling tanks.

The clay leaves the machine in the form of a blanket from one-quarter to one-half of an inch in thickness, from which all the water has been driven except about 25 per cent., and in this form admits of ready drying when required. The process is extraordinarily flexible and, therefore, lends itself to the treatment of many varieties of clay from which many different products are obtained. From some marls and fireclays, considerable quantities of pyrites are obtained, and from others silica in a very finely divided form is separated. From china clay deposits, exceedingly fine mica and sand are obtained. Again, the clay particles themselves vary greatly in fineness, and the very fine particles can be separated from the coarser. This exceedingly fine clay is useful for many purposes, and doubtless many new applications for its use will arise. The finest particles of ball clay are almost jelly-like in fineness.

The cost of working varies widely according to the class of clay treated. The electricity used varies from as low as 20 up to 70 units per ton of machine product.

Another application of electro-osmosis is the electro-osmotic filter press, which has been developed for the de-watering and purifying of many substances in a finely divided state. The press in its simplest form consists of a series of chambers into which the suspension is fed under a head of, say, 10 ft., sufficient to ensure a rapid filling of the chambers. The chambers are closed on both sides by filter cloths in the ordinary way, but the cloths are held in position by perforated or grooved metal or carbon or other conducting plates, one of these plates forming a cathode and one an anode. An electrical pressure of 20 to 100 volts, depending on the substance to be filtered, is established between the plates, and the water is forced towards the cathode. In this press, very fine materials can be de-watered, materials fine enough to choke the ordinary press. This press can be used for filtering clays and many other materials in a colloidal state which are difficult to filter in the ordinary pressure press.

The application of the principles of electrical osmosis are by no means confined to the purification of clay. The applications are, in fact, so many that it is possible in the time at our disposal to refer only to a few examples, such as the tanning of leather, the treatment of metallic slimes produced in various stages of metal purification. The removal of ash from gelatine and the separation of glue and

gelatine into several products has been accomplished.

[The paper was illustrated by a large number of lantern slides and experiments.]

DISCUSSION.

The Chairman (Mr. A. A. Campbell Swinton), in introducing Mr. Highfield, who read the paper, said the subject of electrical osmosis was one that was partly chemical, partly electrical, and partly physical, and in its applications came into the region of engineering, so that it was perhaps reasonable that three authors should have taken part in the paper—Mr. Highfield, who was a member of the Council of the Society and well known in the electrical world, Dr. Ormandy, who was well known in the chemical world and had previously lectured before the Society, and Mr. Northall-Laurie, who was also a distinguished chemist.

Sir Herbert Jackson, K.B.E., F.R.S., said he had bean always interested in electrical osmosis, and at the time during the war when there was some anxiety as to the supply of glass, the hope of getting something better in the way of pots for optical glass was of importance, and it was realised that if the lines pointed out in the paper could be followed it would be of great benefit. The facts were very simple and clear with regard to the advantages of the clay. In his own case, in using an ordinary and well-known form of clay crucible or muffle for experiments, he was very lucky if he could ensure getting anything like 24 hours' work out of it, but it was quite easy to obtain something in the order of ten or fifteen times as much work out of a muffle that was produced from the osmosed clay. He exhibited two specimens of crucibles which had been given to him by the authors, one of which had been baked at a temperature between 800° and 1,000°, and the other had been used as an experiment to see how far it would contract at a higher temperature, and inside it and fused into a mass that was quite soft was some of the clay of a crucible that he at one time used, so that the ordinary clay crucible had fused inside the authors' crucible. When the crucible was being taken out of the furnace, which had a pure silica lining, it had to be lifted out with considerable force, and the silica was drawn out in fine rods, but it was not possible to deform the clay crucible even in taking it out with considerable force. When material was in a fine state of division, so that each particle could exercise its best attraction on the neighbouring particles, a condition of equilibrium and great stability was reached, and when there was stability under heat there was also stability under chemical action for most things. There was great hope that many things which had been difficult to prepare with ordinary clay could be prepared in a state of greater purity and more readily when the process of the osmosed clay was understood thoroughly and became regularly used. He had had the pleasure of meeting Dr. Ormandy and Mr. Highfield some time ago, and took the whole matter up with Dr. Ormandy, and they started out and achieved the brilliant success they had shown that evening, and he felt confident it would be as brilliant a success when carried out on a large scale.

Mr. Walter C. Hancock said those who had had any experience in the preparation of a lecture for such an audience would be very much impressed with the magnificent show the authors had given. The photographs, taken under very high magnification, were really quite triumphs of art. He did not think he would be giving away any secrets if he said that he came to the meeting that afternoon from a place where they had been more or less discussing the problem of the production of glass, and he was happy to say that the production of high-grade optical glass of all descriptions, was now being wrested by this country from many former competitors, and success would depend entirely upon the utilisation of some high-grade refractory material. Up to the present, manufacturers had been content to take the raw material as it was mined and submit it to the most primitive methods of purification. The osmosis process would supersede any method employed hitherto for the production of high-grade china clay and other forms of clay, and a material would be obtained which was capable of resisting the effects of high temperature on the one hand and of chemical action upon the other.

Mr. W. Murray Morrison said he had seen a large number of samples of osmosed clay, and he believed there was a very large field of application for that clay in this country; in fact, it would seem that the field was almost unlimited. The Society was very much indebted to the authors for having brought the subject forward.

Mr. W. H. Patchell said the slides shown on the screen were very beautiful, but the specimens were more fascinating still when seen under the microscope. With regard to the question of colloids, he thought the first strike on record was due to colloid chemistry, when the Egyptians cut off the supply of straw from the Israelites for making bricks. In 1910 he saw the work on osmosis being carried out by Count Schwerin in Germany, and he sent some samples of clay from Cornwall and received most beautiful results from the Count, but he did not appreciate at that time what those samples really meant. They showed a finer clay than could be produced by the ordinary method adopted in Cornwall, but there was no demand in this country for such beautiful products; it was said not to be commercial and so was turned down. About three years later he had one or two interesting interviews with Dr. Ormandy, and after that Sir Herbert Jackson took the matter up. The Cornishman, though generally a Radical, was a most conservative man in his methods. The ordinary Cornish clay washing had gone on with practically no change whatever, and when the offer was made to show the Cornishman better methods it was very difficult to get him to move, and as he could sell more clay than he had been able to produce he really could not be blamed. The difficulty now was not in producing the clay but in getting it out of Cornwall. Where

very pure products were required the new process must be of very great benefit.

Captain C. J. Goodwin said he noticed in a paper by Dr. Ormandy he referred very extensively to the use made of the osmosis process in Germany. It was no secret that Dr. Ormandy and probably some of his colleagues had again visited the Continent, and it would be of great interest to know to what extent the process had been used during and since the war in Germany and other foreign countries. Apparently the industry was in its infancy in this country. He was anxious to know whether anything had been done to apply the process to the drying of peat. It was a very important question at the present time, because of the great shortage of fuel. In some Continental countries, notably Italy, lignite and peat deposits could be very well utilised if they were amenable to that sort of treatment. In the chemical industry of nearly every country there were certain by-products and factory wastes which were to some extent of a colloidal nature, and those products very often contained material which, if it could be sufficiently recovered, would yield a very handsome profit. One of the commonest instances was perhaps sewage, in connection with which considerable use had been made of centrifugal machines and filters. It would be interesting to know how the osmosis process would compare with other methods that were used, and to have some idea of what the cost of treating the clays was, in order to have a comparative basis in considering the problems. There was also the question of the conditions under which various bodies were capable of undergoing osmosis treatment. The authors had dealt almost entirely with suspensions in water, and he would like to know whether the process was at all applicable to materials suspended in other liquids, such as ferric hydrate in a caustic soda solution or arsenical suspensions in sulphuric acid. He noticed that the clay separated out very rapidly, and he would like to know what the weight of separation was, and whether it varied to any considerable extent with different materials. At the present time considerable interest was being taken in the question of suspension of coal dust and other combustible material in oil, to which the generic name of "colloidal fuel" had been given, and it occurred to him that possibly investigation into the time required for the separation might be a useful method of determining the efficiency of those suspensions in oil.

Dr. W. R. Ormandy, in replying to the discussion, said a very fine piece of work was involved in the coloured photographs which necessitated Mr. Northall-Laurie working very late hours, as even the vibration of passing traffic would ruin the photographs altogether. With reference to the remarks of Sir Herbert Jackson, an osmosed clay muffle, made from a certain clay, lasted thirteen journeys, heated up to 1,500° C., as shown by the pyrometer, whereas muffles made from the same clay used by the muffle maker without treatment would never last three journeys. Taking the finest English china clay which had been treated with 97 tons of water in order to wash 3 tons of clay, it was still possible to separate from that clay 7 per cent. by weight of a product which consisted almost entirely of silica and mica and large rouleaux of china clay, which were not broken up or dispersed by the alkali. Mr. Hancock had rather emphasised the point raised by Sir Herbert Jackson that in the manufacture of optical glass there was a great demand for higher grade refractories than were available previously. That was not only due to the mechanical properties of the clay, but for optical purposes it was essential that the clay substance itself should not enter into the mixture in a pot to any appreciable extent. As most fireclays contained a good deal of iron, iron, which was a colouring matter, was introduced. Therefore, for the optical glass maker, it was essential that he should have a crucible which would stand the high temperature and would not be eaten away by the corrosive action of the products which were being melted. In the manufacture of ordinary commercial glass there was a very great opening for the use of clay treated by the osmosis process, because at the present moment the great glass industries of this country, which were being developed to a degree unknown before the war, were severely handicapped by the kind of clay they had to employ for their tank blocks and for making crucibles. There was no question that an osmosed clay, owing to its refractory properties, would resist the corrosive action of the fluid glass in the tank. In the past manufacturers on the Continent had made great progress in the manufacture of glass, and if this country was to gain the industry to supply not only our own requirements but the world's markets, it would be necessary to recognise that the methods that were used by the Egyptians were still largely in use to-day, and were methods that had to be scrapped. It was no use stating that science was a great thing unless the manufacturer was going to support science and apply it. With regard to Mr. Patchell's remarks, many people had the idea that the straw used in Egypt was mixed into the bricks in the form of a binder, but that was not the case. The Egyptians used to put the straw into tanks and allow it to ferment in a hot climate until it went into a colloidal rotting mass, and that was used to mix with the sandy Nile clay in order to make it more plastic. The lack of demand in this country for purified osmosed china clay in the early days merely showed that the users were not sufficiently educated to realise that it paid to use a scientifically purified product. The manufacturers had to be educated, and to a very large extent the directors of some of the big companies needed education. With regard to Captain Goodwin's remarks, the osmosis process was derived primarily from the Continent, where there had been a greater time to develop it. In

Austria there were already china clay works turning out 60 or 70 tons a day, and there were works at Klingerberg being worked by the process, and very large works with seven or eight machines near Coblenz, and plant was already being erected in Spain. With reference to the drying of peat, that was a subject that had occupied his and his colleague's attention very considerably. The osmose filter press was, in his opinion, the only method which had yet been offered that showed a possible outlet for the treatment on a commercial scale of colloidal peats, which could neither be centrifuged nor pressed. Unfortunately the bulk of peat in the world was of a colloidal type. Such peat could be treated by the osmosis process, and he thought no long time would elapse before Mr. Highfield would be in a position to deal with the matter in another paper. Sewage experiments had also been carried out. One of the troubles was that, whereas clay would travel from one pole definitely to the other, in sewage there was a heterogeneous mass of material, some of which went to one pole and some to another, and some had no electrical property whatever and would not move. As far as his own experiments went, there did not appear to be any immediate prospect of the electrical treatment of sewage proving any solution of the difficulty. As to the conditions of use, it was quite obvious that a particle could not move in an electric field if there was a good deal of soluble salts present, and that ruled out the possibility of separating colloidal ferric hydrate from a caustic soda solution, as the soda would convey the current and a very large amount of electricity would have to be used. The only way in which colloids suspended in an electrolyte could be dealt with would be to use a modification of the process. First of all, the electrolytic salts should be removed from the solution, leaving the colloid in a watery solution, and afterwards it could be dealt with in the same way as clay. With regard to the rate of output, that was conditioned to a certain extent by the electric pressure used, but there was an economical rate which it did not pay to exceed. The figure for all clays seemed to be pretty much the same. The purer the clay the larger the output. Coal dust suspended in oil behaved as a pseudo-colloid and was subject to the same laws as clay suspended in water, but that was a branch of the subject which had only just come into prominence. It would have to come into very much greater prominence, because oil was getting in greater demand every day, and the supply was not growing at more than one-third of the rate of the demand, so that the question of mixing coal dust with oil was a problem of the very greatest importance.

Mr. Highfield said it was quite possible to dry peat economically; with a moderate consumption of electricity the water could be forced out of the peat, and when that was done the peat was in the form of little curled up bits of material like cocoanut shavings. The difficulty was to know what to do with the peat in that form. It could be made into a briquette, but that involved a further consumption of energy, and unless it was made into a briquette it was difficult to carry, because it was bulky, and the cost of freight was high. If a peat was mined on a really large scale, tens of thousands of tons a month, the difficulty would be that, as the peat lies in moderately shallow deposit, it would be always running further away from the plant, as the plant could not be placed upon the yielding beds, so that the cost of bringing the peat to the plant was continually increasing and there were many other difficulties to be overcome apart from drying. He had to thank his colleagues for the enormous amount of work they had done on the paper, and Dr. Ormandy for having answered the questions raised in the discussion. He also wished to thank his assistants, who had been of great help in preparing the experiments.

The Chairman, in proposing a hearty vote of thanks to the authors, was sure the audience would agree that the experiments had been beautifully shown, and that the whole demonstration had been a model of its kind.

The motion was carried and the meeting then terminated.

PETROLEUM IN TRINIDAD.

Considerable attention has lately been attracted to Trinidad in connection with the oil boom throughout the world, and there has been a rapid movement to organise new companies to drill for petroleum in the island. Competition for the purchase of lands thought to be oil-bearing has been keen, and prices have been as high as £100 an acre when indications seemed especially favourable. This applies, of course, only to private lands, as all Crown lands in the mineral-oil districts have long since been leased to British companies.

The island of Trinidad has an area of 1,754 square miles. The petroleum indications are confined to the southern part of the island, and particularly along several more or less clearly defined anticlines, which follow an approximately east to west course. The oil-bearing lands of the island are officially defined in the local regulations, as all lands south of latitude 10° 26′ 36″ N. The oil-beds occur in the tertiary strata, which reach a total estimated thickness of from 6,000 to 7,000 ft., and the productive sources are chiefly confined to two main horizons, which show great persistence over long distances.

The southern anticline of Trinidad, where the beds are steeply inclined, has been traced over the whole length of the southern coast, which it closely follows; the crest only occasionally leaves the land and enters the sea, and never passes far from land. A few miles north of the main southern anticline is a second fairly persistent anticline running also in a direction roughly parallel with the southern, but on this anticline

an oil horizon much higher in the series is brought to the surface. Further north are other anticlines, which can be distinctly traced for long distances in some cases, but they are not so clearly defined as the southern and central anticlines.

On the southern anticline there are many petroliferous strata of apparently no great importance outcropping at intervals, but near the crest, where the main oil zone closely approaches the surface and where the sands of the zone are not too thickly covered with clays, indications of petroleum are to be observed on an extensive scale. At many points where the sands of this horizon lie near the surface, important issues of high-grade petroleum may be observed, saturating the surface sands and soils in the vicinity.

The greatest manifestation of petroleum in Trinidad is the famous Asphalt Lake,* which covers a flat area of approximately 120 acres, about twenty-seven miles south of Port of Spain, the capital, and about half a mile from the Gulf of Paria. Early last year a low-depth record of 150 ft. was obtained with difficulty by boring appliances. The asphalt product of this lake contains the heavy constituents of petroleum oil, and was evidently formed from petroleum which had escaped from oil sands.

Another interesting manifestation of petroleum in Trinidad is manjak, a black, solid, friable bitumen, which has evidently been derived from heavy petroleum traversing fissures in clays, which have caused the abstraction of the lighter constituents, leaving only a solid mass. Also, the issue of hydro-carbon gas is another important indication of petroleum, especially on the Cedros Peninsula at the south-western extremity of the island, where there is a long succession of mud volcanoes nearly always in activity, and in which sometimes violent explosions occur. In 1911, just south of the Cedros Peninsula, a small island suddenly formed, but lasted only about a day, having been caused, it is understood, by subterranean explosion of gas. In addition to such indications of petroleum, there were noticed many years ago in Trinidad practically all the essential conditions for the accumulation of oil, if it existed at all. There were beds of sands of sufficient thickness to store large quantities of oil—sands which exhibited a high degree of saturation where exposed. There were also thick coverings of an impervious clay suitable for the preservation of the oil, and there were anticlines where concentration could take place.

It was not, however, until about the year 1901, that any oil was obtained by boring operations. The pioneers of the Trinidad petroleum industry had to face considerable difficulties. Many of the best localities are clothed in dense jungle, through which there are no roads or waterways. Forests have to be cleared and roads made before any machinery can be conveyed to the sites selected. Another considerable difficulty is the prevalence of fevers; camps have to be specially drained, and houses screened from mosquitoes. Gradually, however, companies were formed, several meeting with fair success.

Up to December 31, 1918, according to the local Inspector of Mines, the total number of wells drilled in the colony amounted to 410, of which 236 are on Crown lands and 174 on private lands. There were 41 new wells drilled during 1918 (37 on Crown and 4 on private lands), and in 29 of these oil was struck. There were 12 companies engaged in producing oil at the end of the year 1918. The production of oil in 1918 showed an increase of nearly 30 per cent. over that of the previous year. The total production of oil in 1918 in Imperial gallons (42 Imperial gallons to one barrel) was 72,872,398, as against 56,080,914 in 1917. In 1918, 54,238 ft. were drilled as against 52,037 ft. in 1917. The production of oil on Crown lands in 1918 was just about double the production of oil on private lands. Out of the total production in 1918 of 72,872,398 Imperial gallons, there were 27,920,015 Imperial gallons taken by ships for bunker purposes, 12,936,283 Imperial gallons exported, and the balance of 32,016,100 Imperial gallons used for local consumption. The oil exported was crude petroleum, which was sold to the Admiralty.

According to a report by the United States Consul in Trinidad, at the beginning of 1919 there were twelve companies engaged in producing oil in the island, but only those with considerable capital or financial backing have thus far met with any real success, notwithstanding that it is comparatively easy to find some oil on the anticlines without particularly deep boring; practically all the oil thus far produced coming from shallow sands less than 2,000 ft. deep. The difficulty with production, in the case of every company operating, is, that while wells produce encouragingly at first, the production tends to fall off quickly, and good gushers often become choked by sand very soon. The anticlines are steep, and the pools usually narrow, so that the wells are not very large.

Apparently the best pool in Trinidad is that at Fyzabad, and the success in this district has caused considerable speculation in adjacent lands, and the organisation of new companies to commence operations. About 15,000 barrels of petroleum have recently been produced from three wells adjoining the Fyzabad field. The heaviest oil in the southern fields, including Fyzabad and Brighton, is about 12° Baumé. The best oil from Trinidad runs as high as 45° to 46° Baumé, and will produce 35 to 40 per cent. motor spirit and the same percentage of kerosene. The petroleum from this field is understood to be unsurpassed in quality by any oils found anywhere in the world, but its production up to the present has been comparatively limited.

The principal reasons why Trinidad attracts much attention as a field of possible profitable and continuous development of petroleum industry are: First, the favourable indications of petroleum extending over long distances where there are

* Particulars of this Lake appeared in the *Journal* of 2nd January last, page 109.

unusually extensive displays of natural phenomena, such as are often associated with important oil fields; second, the favourable, though not necessarily ideal, structure which in many cases characterises the strata amidst which the oil sands are distributed; third, the satisfactory yields often obtained from shallow wells drilled at widely separated localities; fourth, the proximity of most of the promising oil districts to the sea; and, fifth, Trinidad's exceptional geographical position with regard to the markets of the world, especially with reference to important routes of commerce. A large number of vessels now equipped to use fuel oil instead of coal find it very convenient to stop at Trinidad to secure oil for bunker purposes. This is especially true of vessels in trade between North and South America, and of those passing through the Panama Canal. Between such ports as Buenos Aires or Rio de Janeiro and New York, it is often extremely convenient for vessels to stop at Trinidad to replenish bunkers with oil, and sometimes continuation of voyages would hardly be possible without calling there to replenish bunkers.

There is also a good local market in the West Indies for petroleum products. In Trinidad itself, fuel oil has now almost entirely supplanted coal for all industrial purposes, owing to its cheapness, its higher calorific efficiency per ton, and its convenience in handling.

The Trinidad Government Railway has lately been equipping its locomotives with oil burners, so that fuel oil can be used instead of coal; and the local Gulf steamers now use oil instead of coal. The municipalities of Port of Spain and San Fernando utilise fuel oil for operating their waterworks; moreover, in Port of Spain, fuel oil is used for operating the tramway system and the electric-lighting plant. Considerable use, also, is made of crude oil on pavements for disinfecting purposes, and, in the campaign against malaria, for preventing stagnant pools of water becoming breeding places for mosquitoes. There is also considerable use of kerosene for lighting purposes.

Although Trinidad as an oil-producing country has advantages as above explained, nevertheless the industry, up to the present time, can hardly be considered to have yielded very favourable financial results—at least as compared with the best-known developments in the United States, Mexico, and other important petroleum-producing countries. The heavy gas pressures and soft shifting formations in Trinidad have proved serious obstacles to economic development, and constant disappointments are experienced by wells gushing most violently at first, and to such an extent that but little of the oil can be saved, and then, perhaps, in a few hours becoming so clogged by rocks and sand that production stops almost as suddenly as it began. The average life of good producing wells is apt to be very short, so that constant investment of new capital is necessary to keep up any large aggregate of production, and constant extension of drilling operations is necessary in order to reap the benefit of heavy outlays upon pipe lines, storage accommodations, shipping facilities, and other works of a permanent character. It seems probable that more scientific attention to the peculiar conditions of Trinidad, as regards its strata levels of soft rocks, shales, sandstones, and clay, with improved methods of drilling to take into account such conditions, would result in more substantial success in producing large quantities of oil and maintaining longer periods of production of wells striking oil.

The most interesting possibilities of the future, as regards the oil industry in Trinidad, might be in drilling wells of far greater depths than have as yet been attempted. In the field of operations of one important company, the policy at present is to deepen existing wells, instead of drilling new ones, and the results thus far seem quite promising; not only more oil, but oil with a world record in quality, has been found at lower depths. But, as yet, there has been no drilling lower than 3,000 ft. The difficulty, which has for some time existed, of securing sufficient supplies of well casing and pipes, has considerably retarded many important operations. Some of the leading geological experts who have visited Trinidad are of the opinion that if drilling operations should ever be conducted considerably below the comparatively shallow depths thus far reached (as has been done in other countries, where great success has been attained), almost unlimited supplies of oil might be found, and the local industry placed on a far more substantial basis than at present.

OBITUARY.

Sir Alexander Baird, Bt.—Information has been received of the death at Cairo of Sir Alexander Baird, who had been a member of the Royal Society of Arts since 1897. He was born in 1849, and was educated at Harrow. In 1879 he was sent to Upper Egypt to engage in famine relief work in the provinces of Girgeh, Kenneh, and Esneh. He was created a baronet in 1897, and was Lord Lieutenant of Kincardineshire since 1889.

NOTES ON BOOKS.

Pyrometry. By Charles R. Darling. Second edition, revised and enlarged. London: E. & F. N. Spon, Ltd. 10*s.* 6*d.* net.

The first edition of this book appeared in 1911. It was founded on the course of Cantor Lectures on "Industrial Pyrometry" delivered by the author before the Society in 1910, and the resultant volume was the first attempt—and a very successful one—to gather together in a handy form the information required by those who make actual daily use of pyrometers.

A great deal of progress has been made in the science and art of pyrometry during the war. New appliances have been introduced and old ones improved. Probably no one has taken a more

active part in this development than the author himself. There are now a great many different kinds of pyrometers in the field, each of which is specially suitable for its own purpose. They are discussed here under the following heads: thermo-electric, resistance, radiation, optical, calorimetric and fusion pyrometers. A chapter on miscellaneous appliances completes an excellent hand-book.

Mr. Darling is well known to Fellows of the Society as an admirably clear lecturer. He is an equally clear writer, and his accounts of the various instruments are models of lucid description.

BLACKIE'S COMPACT ETYMOLOGICAL DICTIONARY. Prepared by Richard John Cunliffe, M.A., LL.B. London, Glasgow, and Bombay: Blackie & Son, Ltd. 2*s*. net.

In these days of inflated prices it is satisfactory to come across a sound, compact etymological dictionary of 380 pages that can be purchased for two shillings. It is based on the highest authorities, and, so far as we have been able to test it, the work has been carried out in a sound and scientific manner throughout. The need to keep the book within small limits, has, of course, made it impossible to include anything like the whole of the current English vocabulary; but the compiler seems to have justified his claim that he has included all words likely to be met with in reading modern works that can be regarded as literature.

A novel feature of this dictionary is an Appendix of terms of special note in modern warfare. The majority of these are legitimate words or phrases, and it is useful to be able to ascertain their precise meaning; but one may perhaps doubt the wisdom of including in a dictionary of this limited size such slang as "Aussies," "Civies," "wangle," and "wash-out."

GENERAL NOTES.

BRITISH MOTOR CYCLE INDUSTRY RESEARCH ASSOCIATION.—The Research Association for the British Motor Cycle and Cycle Car Industry has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. As the Association is to be registered as a non-profit sharing company the promoters have applied to the Board of Trade for the issue of a license under Section 20 of the Companies' (Consolidation) Act of 1908. The Secretary of the Committee engaged in the establishment of this Association is Major H. R. Watling, "The Towers," Warwick Road, Coventry.

ROME SCHOLARSHIPS, 1921.—Particulars are published of the Competitions for the Rome Scholarships in Architecture, Decorative Painting, and Sculpture, offered by the Commissioners for the Exhibition of 1851, for the Rome Scholarship in Engraving, offered by the British School at Rome, and for the Henry Jarvis Studentship, offered by the Royal Institute of British Architects. In each case the offer is of the value of £250 per annum, ordinarily tenable at the British School at Rome for three years. Candidates must be British subjects, and under 30 years of age on July 1st, 1921. The competitions will be in two stages: (1) an open examination, and (2) a final competition open to not more than four candidates selected from those competing in the open examination. Details of the competitions may be obtained from the Hon. General Secretary, Office of the British School at Rome, 1, Lowther Gardens, S.W. 7.

POPULATION OF THE PANAMA CANAL ZONE.—According to a census of the Canal Zone taken by the Police and Fire Division in August, 1919, the total civil population is 21,759, of whom 7,031 are Americans and 14,728 of other nationalities. There are 10,517 men, 4,814 women, and 6,428 children. A year ago the total civil population of the Zone was 21,707, and two years ago it was 23,295. The total number of Government employees is 9,698, of whom 3,317 are Americans and 6,381 of other nationalities.

WOOD FOR BUTTER BOXES.—New Zealand in the past has imported annually over 4,000,000 feet of white pine for butter boxes. Owing to the depletion of its forests, dairymen have become somewhat concerned over the possibility of a shortage of timber, and attempts are being made to discover timber suitable for the butter trade. It is claimed that if mountain ash is properly seasoned and treated it will prove as satisfactory as white pine, and a number of interesting experiments have been made along this line.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JUNE 29...Wireless Society of London, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Anthropological Institute, 50, Great Russell-street, W.C., 3 p.m. Sir C. Hercules Read and Messrs. T. Allworthy, V. B. Crowther-Benyon, S. Fenton, G. W. Willis, and others, "Exhibition of Bronze Age Implements."

Horticultural Society, Vincent-square, Westminster, S.W., 3 p.m. Mr. H. R. Darlington, "Garden Roses."

WEDNESDAY, JUNE 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.

University of London, at the School of Oriental Studies, Finsbury-circus, E.C., 5 p.m. Professor A. J. Toynbee, "The Middle East." Lecture V.—"Dark Age and European Ascendancy (11th to 20th century A.D.)."

Electrical Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 6 p.m. Sir Philip Dawson, "Electric Railway Contact Systems."

Journal of the Royal Society of Arts.

No. 3,528. VOL. LXVIII.

FRIDAY, JULY 2, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The One Hundred and Sixty-sixth Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Fellows, was held in accordance with the By-laws on Wednesday last, June 30th, at 4 p.m., Sir Henry Trueman Wood, Chairman of the Council, in the chair.

The Secretary read the notice convening the meeting, and the Minutes of the last Annual Meeting and of the General Meeting held on August 11th, 1919.

The following candidates were proposed, balloted for, and duly elected Fellows of the Society:—

Baines, Sir Frank, C.B.E., M.V.O., London.
Baines, Hubert, C.B.E., London.
Blakemore, Frederick William, A.C.I.S., Timperley, near Manchester.
Booth, Frederick Augustus, Harborne, Birmingham.
Boys, Captain Henry Cecil, M.B.E., London.
Burrow, Edward John, Cheltenham.
Button, Norman, London.
Cherry, John Arnold, C.I.E., Bombay, India.
Freeland, Major-General Sir Henry, K.C.I.E., C.B., D.S.O., M.V.O., Bombay, India.
Gill, John Hamblet, London.
Goodwin, Engineer Vice-Admiral Sir George Goodwin, R.N., K.C.B., Sutton, Surrey.
Green, L. B., M.B.E., Madras, India.
Gupta, N., C.I.E., Calcutta, India.
Haggar, James Joseph Percival, Flixton, Lancashire.
Hakes, James A., Sunbury-on-Thames.
Halsall, Charles Frederick, M.I.A.E., London.
Hartigan, Lieut.-Colonel Marcus Michael, C.M.G., D.S.O., Ashford, Middlesex.
Hegarty, R. D., London.
Holmes, Henry Cresswell, Gosforth, Newcastle-on-Tyne.
Hosken, Richard, Assoc.M.Inst.C.E., M.I.M.E., London.
Jonason, Otto Axel Ragnar, Hull.
Kent, T. O., East Molesey, Surrey.
Locke, Miss M. Katherine, Youngstown, Ohio, U.S.A.
Long, Burt, Horley, Surrey.
Mehta, Jehangir K. B., Bombay, India.
Miller, Frank, Beckenham, Kent.
Nicholson, John Hatfield, Radlett, Herts.
Osborne, F. B., London.
Peters, Thomas, Sydney, New South Wales, Australia.
Phillips, Randolph Warrington, London.
Pike, Clement Allin, London.
Preater, Charles John, M.Inst.Met., Bath.
Preston, W. E., London.
Rose, Lieut. L. W., Jerusalem, Palestine.
Rowlands, Joseph, J.P., Malvern.
Rutherford, Henry, London.
Sarasasna, Lieut.-Colonel Bra, Bangkok, Siam.
Shalders, John Frederic, Rio de Janeiro, Brazil, South America.
Smith, George, London.
Sprott, Ernest W., London.
Stuart, John Matthew Blackwood, B.A., Enniskillen, Ireland.

Sykes, W., Chicago, Illinois, U.S.A.
Tarrant, Ernest Frederick, London.
Timbrell, W. H., Foochow, Fukien, China.
Tullis, John, B.Sc., London.
Walker, E. M., Terre Haute, Indiana, U.S.A.
Williams, C. Harold, Llanelly.

Honorary Corresponding Fellow:—

Vegas, Santiago, Caracas, Venezuela.

The Chairman appointed Mr. Frank Cundall and Mr. Henry Hill scrutineers, and declared the ballot open.

The Secretary then read the following—

REPORT OF COUNCIL.

I.—Introduction.

At the close of the Society's 166th Session, the Council are glad to be able to congratulate the Fellows on a year's work, which in all respects but one—finance—has been entirely successful. The number of Fellows elected since last June is again a record, being 479, as compared with 455 in 1918-19, the previous highest figure. The entries for the Society's

Examinations also constitute a record, the number this year being 54,010, as compared with 37,973 in 1914, the previous highest figure. In spite of these facts, however, the question of finance has caused the Council grave anxiety. Although the income from subscriptions rose from £5,780 in 1918 to £6,261 in 1919, the costs of printing, paper, and general maintenance charges have increased in still greater proportion, and the Council have reluctantly come to the conclusion that it is no longer possible to carry on the work of the Society at the present subscription of £2 2*s.*—a sum which has remained unaltered since 1754, when the purchasing power of money was hardly comparable with its purchasing power to-day. Accordingly, with the unanimous support of the Council, the Chairman has undertaken to move, at the Annual General Meeting, that the annual subscription be increased to £3 3*s.*

II.—Ordinary Meetings.

Sir Henry Trueman Wood, Chairman of the Council, selected as the subject of his opening address, "Science and Industry." He sketched the industrial history of this country during the last century, and showed that the Society had played an effective part in the development of inventions and industries. After a brilliant review of the past, he turned to some of the problems of the present and future, such as the steps taken by the Government to promote scientific and industrial research, and the provision of new sources of power.

Dr. H. B. Morse outlined the history of British trade in China from 1637, when the first English ship arrived in Canton, to the present day. In the course of his paper he gave some striking statistics illustrating the growth and decline of this trade. In 1833, 58·1 per cent. of Chinese exports went to the United Kingdom; in 1867 this percentage had risen to 66·6; while in 1905 it fell to 7·0. Similarly, English percentages of the total imports into China were:—in 1833, 10·5; in 1867, 41·3; and in 1905, 23·5. The principal causes for the decline in the percentages in recent years are threefold: (1) The United Kingdom no longer buys tea in great quantities from China, but takes it principally from her own empire—India and Ceylon; (2) We have not taken our proper share in developing the new export trade of China; oil seeds go to Japan, France and (before the war) to Germany; fibres mainly to Germany, and so forth; while (3) silk, of which London used to be the Western world's market, goes largely to Lyons and Milan. Dr. Morse concluded by giving some suggestions which might lead to the improvement of our position with respect to Chinese trade, the principal of which were the prompt publication of commercial information by the British Government, the encouraging of Chinese students to come to this country for education, and the discovery of the best method of advertising British goods in China.

The seed-crushing industry has made enormous strides during recent years, and probably no one has contributed more to its development than Mr. J. W. Pearson, who read a paper on the subject at the third Ordinary Meeting. After dealing with the materials, the greater portion of which are produced within the British Empire, mainly in the Torrid Zone, Mr. Pearson described the principal kinds of manufacturing plant which perform the operations of cleaning, rolling, cooking, pressing and paring. He also referred to the chemical process of extracting oil, a process in much more general use in Northern Europe than in this country. The final portion of the paper was devoted to the products, which are very numerous and varied, and it is in this connection that the most interesting developments have taken place in recent years. There is an enormous and rapidly-growing demand for vegetable oils of all descriptions—the home output of margarine alone has risen from 2,000 tons per week before the war, to 10,000 tons per week to-day—and modern invention is directed to securing the utmost utilisation of the raw materials, and the elimination of waste at every stage. Reference was made to the hydrogenating process, in which pre-neutralised oil is exposed to a stream of heated hydrogen gas in the presence of a catalyst. Mr. Pearson described this as "probably the most interesting process of recent date." The action of the catalyst is not yet completely understood, but the results are remarkable. Liquid oils can be converted into hard oils at a cost of about £5 a ton, and as hard oils have always commanded a premium of from £10 to £15 a ton over liquid oils, it will be seen that a great future lies before this process.

Sir Oliver Lodge's Trueman Wood Lecture was in every way a worthy successor to the two brilliant lectures delivered by Sir Dugald Clerk and by Sir Herbert Jackson. He selected as his subject, "Sources of Power, Known and Unknown." In the first part he dealt briefly with coal, water, the sun, the internal heat of the earth, and the tides as sources of energy; the second part he devoted to consideration of

the energy of the atom. The subject is full of most intricate difficulties, and our study of it only dates back some twenty years; but Sir Oliver contrived to place before his audience a vivid presentment of the atomic world, and suggested possibilities of practical developments that have as yet been hardly dreamt of by engineers.

At a time when it was difficult to obtain any information as to the true condition of Russia, except such as was to be found in the more or less sensational articles in the Press, the Council welcomed a sane and well-informed statement from Mr. Constantine Grunwald, who was formerly Chief of the Intelligence Department of the Russian Ministry of Trade, and is now General Secretary to the Russian Manufacturers' and Merchants' Association in London. In spite of the terrible conditions brought about by Bolshevism, there are circumstances which make the plight of Russia far from hopeless. The natural resources of the country are boundless, and, given improved means of transport, these could be rapidly developed. The Russian Consul-General, who spoke in the discussion, went so far as to say that after the first good post-war harvest Russia would be rich again. The first thing to aim at is political peace and security. Mr. Grunwald appealed to this country to assist Russia in reconstructing herself, and not to allow Germany to secure full control of Russian resources in raw materials.

Mr. Alfred H. Powell, in his paper on "Ancient Cottages and Modern Requirements," made a double plea for the preservation of ancient cottages on the ground of their artistic beauty, and because they can in many cases be placed in good habitable repair at less than the cost of a new cottage. He gave some general directions as to the lines to be adopted in making an old cottage fit for use without destroying the qualities which it owes to age. No old cottage need be pulled down so long as its outer shell is still in fair condition. The Secretary of the Society for the Protection of Ancient Buildings, who spoke in the discussion, stated that his Society was anxious to purchase an old cottage and restore it on approved lines, and then issue an illustrated pamphlet showing the various stages in the process, which would be distributed throughout the country as a guide to district councils. It is satisfactory to note that, as a result of the meeting, a gentleman promised the sum of £500, which it was estimated would be sufficient for the purpose in view.

Sir Cecil Hertslet, who lived in Antwerp for fifteen years as British Consul-General, read an able and eloquent paper on "The Ruin and Restoration of Belgium." He gave some striking illustrations of the systematic ruin worked by the Germans in the Belgian factories with the avowed object of endeavouring to prevent Belgium from competing with Germany as an industrial country for many years to come. It is to be hoped, however, that this diabolical purpose will be frustrated. The Belgian workmen, after years of idleness forced upon them under the German occupation of their country, are tired of doing nothing and eager to work. The port of Antwerp, which was becoming a grass-grown wilderness, is rapidly returning to its pre-war activities; the blast furnaces, which were re-reduced from fifty-four to one, have already increased again to eleven; while the number of cotton spindles produced in November last was 1,200,000, as compared with an average of 1,700,000 in pre-war days.

In his paper on "The English Language and International Trade," Mr. Alfred E Hayes gave an interesting account of the work which he had carried out on the invitation of the Danish Government to conduct in Denmark summer courses in English for Danish teachers. The courses were attended by students who were eager to learn not only the English language, but English ways of thought, and to study English books, and Mr. Hayes's ideal is to establish similar organisations in all foreign countries. Before the war the German Government spent large sums of money in familiarising other nations with the German language or German thought. The British Government has hitherto spent little or nothing in this direction, although it is obvious that this country can only derive benefits from such activities—benefits to which it is impossible to set limits. In the first place they would probably lead to large sales of British books abroad, to a fuller understanding of British life and methods, and, by encouraging friendly feelings between Britain and other nations, to an expansion of her trade with them.

Lieut.-Commander Norman Wilkinson made clear—what must have been a puzzle to many people—the principles on which the Admiralty acted in camouflaging ships. The extraordinary effects with which one became familiar during the last two years of the war, were obviously not devised to secure invisibility. Lieut.-Commander Wilkinson showed in his paper that, owing to continual changes of colour of sky and sea, such invisibility would always be quite unobtain-

able: if you painted a ship to be invisible against a dark sky and sea, it would stand out clearly defined on a bright sunny day. The object aimed at was quite other than this: it was so to break up the outline of a ship that the commander of an attacking submarine would be baffled and unable to decide exactly what course she was steering, and so hesitate as to what position he should take up in order to attack with success. That the results—which were largely due to the invention of Lieut.-Commander Wilkinson—were extraordinarily confusing it is impossible to doubt; and though there are, of course, no means of estimating how many ships were saved by "dazzle painting," the highest authorities are agreed that they were very numerous.

Among many problems whose importance has been emphasized by the war and by the subsequent increase of prices, not the least vital is the question of transport. Two papers on very different aspects of it were read during the session: the first, by Mr. Sidney Preston, on "English Canals and Inland Waterways," the second, by Air-Commodore Edward Maitland, on "The Commercial Future of Airships." English canals to-day are very much as they were when they were first constructed: for various causes they have been left *in statu quo* while other means of locomotion have been developed. If they have become out of date, then, is there much cause for wonder? As Mr. Preston remarked, "Could one imagine what would be the present state of motor traffic if the roads of England were in the same condition as they were before Macadam lived, and if they had been dependent for development and improvement on the Turnpike tolls?" Yet it seems obvious that for certain classes of traffic—heavy goods for the delivery of which there is no immediate hurry—the barge is excellently suited. During the war the canals were, of course, taken over by the Government, and were under the Canal Control Committee, of which Mr. Preston became Chairman. The problem as to what is to be done with the canals now is awaiting solution by the Ministry of Transport. It is an exceedingly difficult one, involving financial considerations of the most complicated kind. A survey of the whole situation was given in the paper.

If there has been no progress in the development of canal traffic for a century, the airship as a commercial vehicle is improving day by day. Up till now it has only been used for military purposes in this country, but in Germany considerable attention has been paid to its commercial possibilities. Air-Commodore Maitland went into considerable detail in estimating the cost of airships, bases, maintenance, depreciation, salaries of crews, etc., and arrived at the conclusion that the present "all-in" cost per ton-mile would be about 2*s.* 9*d.*, though he expressed the hope that, making reasonable allowance for operational improvements, this figure might soon be reduced to 1*s.* 9*d.* The saving of time is, of course, very great. Thus Egypt could be reached in two days, India in four and a half days, South Africa in six days, and Australia in nine and a half days. With our rapidly increasing knowledge of meteorology it seems fair to hope that regular services might be maintained. There is one other aspect of the question which deserves to be borne in mind. A commercial airship can be turned into a military airship as easily as a merchant vessel of the Elizabethan day could be turned into a fighting ship, and in any war of the future the military airship must play an important part, while the crews that run the airship in time of peace will provide the skilled hands to man it in time of war.

The necessity of creating in the shortest possible time a large amount of skilled labour for the production of munitions led to the establishment of the Training Department of the Ministry of Labour. The work of this Department was described by Mr. (now Sir) James Currie, who has been for some time responsible for its conduct. The nature of the problem which he had to deal with has undergone a gradual change: at first the main object of the Department was to secure the output of munitions, and with this end in view large numbers of women had to be rapidly trained; now the main object is to train men—many of them disabled soldiers—in engineering and other industrial trades. It is estimated that the number of disabled men who will require training facilities is not far short of 80,000, so that the problem is a formidable one. Mr. Currie outlined the schemes which he divided into (1) training in technical schools; (2) training in instructional factories; and (3) training in instructional bays attached to factories.

Comparatively little is known of the vast area called Mongolia. It has attracted few travellers, probably because the methods of transport are of the most primitive kind, and large parts of the country are bare and inhospitable. In a paper called "Mongolia from the Commercial Point of View," Mr. William James Garnett described a seven months' journey which

he made there in 1908, mostly on camel back. While he thinks it will be a long time before the Mongols can be consumers to any considerable extent, he believes that the resources of the country are quite unknown, and that it could support a much larger population and more stock than it at present holds. In the days of the great Khans, Mongolia appears to have been a very much wealthier and more prosperous country than it is now. Mr. Garnett thinks it might be restored to that position, but the problem is, who will develop its resources? The Mongols are evidently incapable of doing so. Possibly the Chinese may undertake the task.

Mr. H. M. Thornton had already read before the Society two papers on the uses of coal gas in industry. During the war great advances were made in this direction, and in his paper, "Gas in relation to Increased Output and National Economy," he summarised the results of this development. The subject was dealt with under four heads: (1) The eliminating of waste; (2) the cheapening of production; (3) the speeding-up of output; and (4) the human element, or improvement of working conditions. Owing to the fact that it is possible to regulate the heat of gas-fired furnaces with great precision, there is little danger of wasting material in consequence of subjecting it to too high or too low temperatures, and by using gas it is also possible to save all the valuable by-products of coal. A double economy was claimed for the gas furnace, as compared with the coke furnace: not only is the value of the gas consumed less than that of the coke consumed, but the amount of labour required to attend to gas furnaces is also considerably less than that required for coke furnaces. Further, the gas furnace is cleaner and more easily handled, and evidence from several works was quoted by Mr. Thornton showing that in cases where gas furnaces had been introduced, even though at first the men were disposed to resent them, they had soon become their warm partisans.

Mr. W. Worby Beaumont's paper on "Street Passenger Transport in London" resolved itself into a discussion on the relative merits of motor omnibuses and tramcars. The tramcar suffers from obvious disabilities: it cannot leave the lines on which it runs, and in the event of a breakdown all the cars on the line affected may be held up. The motor omnibus, on the other hand, is comparatively handy; it can thread its way through traffic and is an independent unit. Moreover, it has no need of tram-lines, which are injurious to the tyres of other vehicles. Mr. Worby Beaumont also claimed that the tramcar as it exists to-day is unduly expensive, both in its construction and in the amount of horse-power necessary to enable it to run at high speed while frequently stopping. The paper was followed by a keen discussion, in which the champions of the tramcar maintained that in the present conditions of London traffic, when there are enormous rushes in the mornings and the evenings, the tramcar is an absolute necessity that cannot be dispensed with.

In a paper, of which it was only found possible to publish a *résumé* in the *Journal*, Mr. Joseph Thorp defined the basic principles of good printing. Adopting as his criterion "fitness for purpose," he insisted on legibility as the first necessity. His next point was the proportions of the page, the relative widths of margins, etc., which are very important in determining whether a book is attractive to read or not. The ideal lengths of the line were considered in relation to the size of the type, and finally the question of ornament was discussed. This needs the most careful restraint, and, unless treated with the soundest judgment, interferes at once with the legibility of the print and with its really artistic appearance.

Dr. C. E. Kenneth Mees gave an exceedingly interesting account of the Kodak Research Laboratory at Rochester, New York State, where he has been working for the last eight years. He described in some detail the building itself, the largest of its kind in the world, and then proceeded to give an account of the kind of work conducted there in connection with the physical, chemical and practical aspects of photography. He showed the methods by which the study of sensitive materials is conducted, and exhibited a number of slides illustrating the microscopic structure of silver bromide grains, etc.

Mr. Leon Gaster, who has already read papers and delivered a course of Cantor Lectures before the Society on various aspects of illumination, dealt with the question of Industrial Lighting and its Relation to Efficiency. There is no doubt that a large number of industrial accidents are due to inefficient lighting: Mr. Gaster quoted statistics of American experiments which demonstrated this beyond a doubt; and it follows therefore that the prevention of accidents due to this cause is amply justified on economic grounds alone, to say nothing of the humanitarian side of the argument. The increase of output which attends improved illumination is equally marked, and is out of all proportion

to the increase of cost which such improvement involves. Roughly, the lighting of a factory costs only 1 per cent. of the wages bill, so that the expense of any desirable improvement of lighting is comparatively negligible. The vital importance of good illumination as regards safety, health, and efficiency of work is now so generally recognised that in Mr. Gaster's opinion the time has come when definite requirements as to lighting should be inserted in the Factory Act, as is already done in the case of heating and ventilation.

Brigadier-General Charles H. Sherrill has made a life-long study of stained glass, and has written two excellent works on the subject—"Stained Glass Tours in France," and "Stained Glass Tours in England." In the paper which he read in April last he gave a charming account of the principal stained glass in England and France. Beginning with some twelfth and thirteenth century examples of the *peintres-verriers'* art in France, he showed a very large number of slides which included almost all the best-known windows in the two countries. The slides were made by the autochrome process of photography, and gave an excellent idea of the beauties of the originals.

At a time when the country is being flooded with war memorials of all descriptions, a paper by Mr. Graily Hewitt on Rolls of Honour was opportune. The author is generally recognised as one of the finest penmen living, and he has done as much as anyone to improve the style of British lettering. He dealt not only with the form of the inscriptions, but also with the various materials—stone, brass, copper, parchment, etc., —on which they may be written, and he further gave some excellent advice as to the way in which they should be worded. Unfortunately, many of the examples which one sees contain all the worst faults that he condemned. It is to be hoped that his paper, which was much appreciated by his audience, will have some effect in improving both the style and the matter of those rolls of honour which are still to be carried out.

The paper read at the last ordinary meeting of the Session, on "The Commercial Application of Electrical Osmosis," by Mr. J. S. Highfield, Dr. W. R. Ormandy, and Mr. D. Northall-Laurie, was one of very great interest and importance. Electrical osmosis is a process that may be applied to a great many materials. For the purposes of this paper the authors dealt mainly with its application to clays, and the process was illustrated with a number of striking experiments and some very beautiful lantern slides. Stated briefly, the process is as follows:—"If in the prepared suspension [*e.g.*, liquid clay] two electrodes are immersed, and a difference of electrical potential be established between them, the clay particles move to the anode, where they discharge themselves and adhere as a coagulated mass, and the water is driven to the cathode, leaving the clay in a semi-dry state attached to the anode." A demonstration was given in which a quantity of china clay was reduced to a condition of great purity in a very short time; and, in the discussion which followed the paper, evidence was given that crucibles made of osmosed clay were vastly superior in length of life and other qualities to crucibles made of materials treated in the ordinary way.

III.—Indian and Colonial Sections.

The Indian Section held seven successful meetings, and the Colonial Section three. There was also, for the first time, a joint meeting of the two sections.

The Indian papers, taking them in chronological order, were:—(1) "Some Problems of Indian Education," by Mr. P. J. Hartog, member of the Calcutta University Commission; (2) "Burmese Village Industries," by Mr. A. P. Morris, Art Officer to the Government of Burma; (3) "The Indian Currency System," by Sir William Meyer; (4) "The Ports of India," by Sir George Buchanan, well known in connection with large engineering undertakings in the East; (5) "Roads and Motor Transport in India," by Brig.-Gen. Lord Montagu of Beaulieu, for five years, 1915–1919, Adviser on Mechanical Transport Services in India; and (6) "The Improvement of Crop Production in India," by Mr. A. Howard, the distinguished Imperial Economic Botanist to the Government of India. At the seventh Indian meeting, the first annual Sir George Birdwood Memorial Lecture was delivered by Sir Valentine Chirol.

Mr. Hartog dealt principally with the educational problems of the great province with which he is best acquainted—Bengal; but he also touched on their bearings on the peninsula as a whole. Not the least suggestive of the topics embraced in a singularly comprehensive and lucid survey was: How far will Europeans continue to play a part in Indian education? Mr. Morris set out to show that the encouragement of some Burmese handicrafts is desirable, that in certain cases the causes which have weakened domestic industries might be removed, and that others have already been improved by

aid which is not "mere benevolent bolstering." Sir William Meyer abstained from all "polemical preachings," his masterly paper being mainly an historical account of the Indian currency system, and the ways in which it has been developed to meet the stress of very varying circumstances. Sir George Buchanan argued that unless there is a change in the method of administering and developing Indian ports it will be impossible for them to keep pace with the requirements of an increasing trade. He recommended the creation of a Department of Communications, and the Secretary of State for India, Mr. E. S. Montagu, M.P., who occupied the chair, announced that such a scheme is now under consideration. Lord Montagu of Beaulieu made proposals for the improvement of Indian roads, including the establishment of a Road Department. He pointed out the need for types of transport vehicles specially designed for tropical use. Mr. Howard, besides exhaustively dealing with the lines of advance in crop production through the plant, indicated the wide range of the agricultural problems in a country whose greatest industry is, and must for a long time be, agriculture. Sir Valentine Chirol in selecting the subject of his brilliant lecture, "The Enduring Power of Hinduism," was chiefly moved by the desire to find one with which Sir George Birdwood would have been in full sympathy.

The papers read before the Colonial Section were: "Problems of the West Indies," by Sir Edward Davson; "Tropical Departments of Agriculture," by Sir Francis Watts; and "Trade Routes for the British Empire in Africa," by Mr. G. F. Scott Elliot. Federation of our oldest group of colonies and labour difficulties were amongst the many points treated by Sir Edward Davson in his able paper. He cordially supported the proposal to provide the West Indies with a College of Tropical Agriculture, the urgent need for which was also emphasised later by its most prominent advocate, Sir Francis Watts. The purpose of Mr. Scott Elliot's interesting paper was to make the general public realise our present opportunities in Africa, and to enforce the necessity for the adoption of a carefully-planned scheme of development in the most backward of all the Continents.

The enormously important question treated at the joint meeting, the Empire's oil resources, was in the very capable hands of Sir John Cadman. The value, at this moment, of his paper, and of the remarks made in the discussion by Mr. E. G. Pretyman, M.P., late Civil Lord of the Admiralty, "probably the first to see with a statesman's clear vision the coming of the Oil Age, and the need for an Empire oil policy," as Sir John Cadman observed, by Sir Marcus Samuel and by others, can hardly be overestimated.

IV.—Cantor Lectures.

The first course of Cantor Lectures, delivered by Dr. John Theodore Hewitt, dealt with the subject "Synthetic Drugs." The lecturer explained the chemical action in the manufacture of the simple aliphatic compounds; ketones and their derivatives, such as sulphonal; veronal; the non-aromatic cyclic compounds; phenol; salicylic acid; derivatives of the aromatic amines and amino phenols; compounds of heterocyclic structure, such as antipyrine, flavine, etc.; modified alkaloids; and the organic compounds of arsenic, antimony, mercury, and other metals.

Captain H. Hamshaw Thomas, who delivered the second course, chose as his subject "Aircraft Photography in War and Peace." He described the great strides which had been made during the war in the taking of aerial photographs and the development of the aerial camera. He then discussed the value of aerial photographs in war, the types of intelligence which they furnished, the kind of training necessary in order to learn how to interpret them intelligently and correctly, and the effects which air photography would have in modifying strategy. In his last lecture he turned to the uses of aerial photography in times of peace, showing how it might be employed in compiling or improving maps, and generally applied in exploration and survey work.

Mr. C. F. Cross gave the third course on "Recent Research in Cellulose Industry." The subject covers a great variety of problems, many of which are of great importance to large industries. Jute, esparto and other wood fibres used in paper manufacture, cotton, twisted paper yarns, cotton and artificial silk, were all discussed by the lecturer, who gave an account of the latest researches in these matters and suggested possibilities of further developments.

The fourth course, on "Aluminium and its Alloys," was delivered by Dr. Walter Rosenhain. A great deal of work has been carried out during the war in investigating the properties of these alloys—much of it under the supervision of the lecturer at the National Physical Laboratory—and the results were summarized in this course.

The properties of various alloys—with copper, with zinc, with zinc and copper, and with more complex ingredients—were described; their composition, microstructure and physical properties were illustrated, and the various objects for which they were specially suitable were fully dealt with.

The fifth and final course was delivered by Mr. Arthur Thomas Bolton on "The Decoration and Architecture of Robert Adam and Sir John Sloane, 1758–1837." The general position of English architecture at the time of Robert Adam's return from Italy in 1758 was described, and the lecturer traced the revolution of taste brought about by his new ideas. The principal features of his scheme of architecture and decoration, now known as the Adam style, were fully illustrated with the aid of very numerous and admirable slides. Sir John Soane's relations to the movement begun by Robert Adam, and to the Greek and Mediæval revivals, were also traced, and his ideas on architecture and decoration were discussed in relation to his more important works.

V.—Juvenile Lectures.

A course of two Juvenile Lectures on "Railways and Engines" was given by Mr. Loughnan Pendred, Editor of *The Engineer*. With the aid of a large number of lantern slides and working models, the lecturer gave an excellent idea of the development of railways, the first of which, the Stockton and Darlington, was not opened till 1825—only ninety-five years ago. Models of Murdock's road locomotive, of Brunton's curious engine that was propelled by a pair of legs, and of Hedley's "Puffing Billy" were shown and their action explained; while in striking contrast with these were models of some of the latest locomotives of the North Eastern, London and North Western, and Midland Railways. In the second lecture the working of the engine was carefully explained, and the various methods of signalling were described and illustrated.

VI.—Scheme for the Promotion of Industrial Art.

In pursuance of their scheme for the Promotion of Industrial Art, the Council called a Conference on House Furnishings,* which was held in connection with the Ideal Home Exhibition at Olympia on February 19th. The chair was taken by the Right Hon. Sir Auckland Geddes, then President of the Board of Trade; speeches were delivered by Sir Henry Trueman Wood and Sir Frank Baines, Principal Architect of H.M. Office of Works, and these were followed by a general discussion. At the close of the meeting a resolution was passed approving the formation of a small committee, containing representatives of the various trades concerned, "to investigate further with a view to securing a concrete issue of the propaganda undertaken by the Society." The Industrial Art Committee have since held several informal meetings with various manufacturers of furniture, and they hope to call another conference at an early date, when it is believed that Sir Frank Baines will be able to place before the trade some definite proposals.

* A full report of the Conference was published in the *Journal*, Vol. LXVIII. pp. 248-258.

VII.—Albert Medal.

The Albert Medal of the Society for 1920 has been awarded by the Council, with the approval of the President, H.R.H. the Duke of Connaught and Strathearn, K.G., to Professor Albert Abraham Michelson, For.Memb.R.S., whose optical inventions have rendered possible the reproduction of accurate metric standards, and have provided the means of carrying out measurements with a minute precision hitherto unobtainable.

It is a matter of common knowledge that the two great standards of length, the French metre and the British yard, are neither of them based on scientific principles, but are purely arbitrary measures. The metre is the length of a metal bar, which was approved by decree in 1799 and deposited in the French Archives. The British yard is the length of a metal bar. or rather the length between certain marks on the bar, finally approved by an Act of 1878, and in the keeping of the Board of Trade. The metre was originally intended to be one ten-millionth part of a quarter meridian arc measured from the North Pole to the Equator, but it has never been found possible to calculate this arc with sufficient accuracy, and the standard metre is a little shorter than the true or theoretical metre, according to the nearest calculations of the length of a quarter of the Earth's polar circumference. The British yard never professed to be anything but a purely arbitrary measure.

Numerous attempts have been made to discover some natural constant which might provide a basis for a standard of length. The length of a pendulum beating seconds (or an aliquot part, such as a third) has been suggested. In 1774 this Society offered a Gold Medal for an invariable standard of weights and measures,

but without result. The problem had, in fact, been considered insoluble until in or about 1893 Professor Michelson discovered that the length of the metre might be stated in terms of wave-lengths of light. He found, by the use of his improved interferometer, that in the length of the standard metre there were 1,553,164 wave-lengths of the red line of cadmium, and this result was verified in 1906 by Perot and Fabry. It is believed that the calculation is correct within two millionths of a millimetre, and it therefore provides a means by which, if the standard metre were lost or destroyed (with all its copies), it could be reproduced with absolute accuracy.

Professor Michelson's numerous contributions to purely scientific research have been recognised by the award of the Copley Medal of the Royal Society and of the Nobel Prize for Physics, both in 1907.

VIII.—Medals for Papers.

The Council decided to award eight medals for the papers read before the Society during the present session—four for papers read at Ordinary Meetings, two for those read in the Indian Section, one for those read in the Colonial Section, and one for that read at a joint meeting of the Indian and Colonial Sections.

The following awards have been made :—

Papers read at the Ordinary Meetings :—

John Westall Pearson, "The Seed Crushing Industry."

Sidney Preston, C.I.E., "English Canals and Inland Waterways."

Sir James Currie, K.B.E., C.M.G., "Industrial Training."

Air-Commodore Edward Maitland, C.M.G., D.S.O., A.F.C., "The Commercial Future of Airships."

Papers read in the Indian Section :—

Sir William Stevenson Meyer, G.C.I.E., K.C.S.I., "The Indian Currency System and its Developments."

Albert Howard, C.I.E., M.A., F.L.S., "The Improvement of Crop Production in India."

Paper read in the Colonial Section :—

Sir Francis Watts, K.C.M.G., D.Sc., "Tropical Departments of Agriculture, with special reference to the West Indies."

Paper read at a Joint Meeting of the Indian and Colonial Sections :—

Sir John Cadman, K.C.M.G., D.Sc., "The Oil Resources of the British Empire."

For many years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society or who were members of the Council. Acting on this rule, the Council were precluded from considering the following papers :—

At the Ordinary Meetings :—

Horace M. Thornton, "Gas in Relation to Industrial Production and National Economy."

William Worby Beaumont, M.Inst.C.E., "Street Passenger Transport of London."

Leon Gaster, "Industrial Lighting and its relation to Efficiency."

Dr. C. E. Kenneth Mees, "A Photographic Research Laboratory."

John Somerville Highfield, M.Inst.C.E., M.I.E.E., W. R. Ormandy, D.Sc., and D. Northall Laurie, F.I.C., "The Commercial Application of Electrical Osmosis."

In the Indian Section :—

P. J. Hartog, C.I.E., M.A., "Some Problems of Indian Education."

Sir George Cunningham Buchanan, K.C.I.E., M.Inst.C.E., "The Ports of India: their Administration and Development."

Brigadier-General Lord Montagu of Beaulieu, K.C.I.E., C.S.I., "Roads and Motor Transport in India."

The Council, however, desire to express their appreciation of these papers.

IX.—Owen Jones Prizes.

The competition for the Owen Jones Prizes was conducted on the lines followed during the last three years. By the kind permission of the Director of the Victoria and Albert Museum, the necessary accommodation and facilities for judging the work in the Museum were placed at the disposal of the Council.

In 1919 the competition was limited to designs for:—(1) Architectural Decoration, including Stained Glass, Mosaic for Walls and Floors, Plasterwork in relief and incised, Inlaid Marble and Stones, and Lettering for Memorials; (2) Woodwork and Cabinet Work, including Carving in Wood, Ivory and Bone, Inlay, Chairs, Chests, and Cabinets; (3) Textiles, including Tapestries, Carpets and Rugs, Moquettes and Floor Coverings (*e.g.*, Linoleums and Floor-Cloths). Fifty designs were sent in from nine Schools of Art by thirty-one students. These numbers showed a slight increase over those of 1918, when thirty-seven designs were submitted from nine schools by thirty-one students, but they were still far below the numbers for 1917, when one hundred and twenty designs were submitted from twenty-two schools by seventy-three students. There is little doubt that the smallness of the entries in

1918 and 1919 was mainly due to the effects of the war, which had very largely reduced the numbers of those attending the Schools of Art.

According to the report of the judges,* the quality of the work was as disappointing as the quantity, and they only felt themselves able to award two out of the six prizes offered. In order to encourage the competition, the Council decided to offer in 1920 and the two following years an additional prize of £20 for the best design submitted, irrespective of class.

The work was exhibited to the public at the Museum from July 21st to August 30th.

Full particulars of the conditions of the competition in 1920 were published in the *Journal* of November 7th last (p. 779). The designs for this year's competition had to be delivered at the Victoria and Albert Museum between June 21st and 26th.

X.—Examinations.

The extraordinary demand for educational facilities, which has filled to overflowing every university, college, and evening school in the country, has had its effect on the Society's examinations, the entries for which have increased in a most remarkable manner. For purposes of comparison the figures are given below for the present and two previous years — 1914, the previous record year, and 1919:—

Year.	*Number of entries.*
1914	37,974
1919	34,173
1920	54,010

The increase is no doubt due in part to the prizes of the value of £1,000 which were offered by the proprietors of the *Daily Sketch* for shorthand-typists †; but these probably only account for the increase in the three subjects in which the prizes are offered, viz., Shorthand, Typewriting, and English. There have also been great increases in other subjects, *e.g.*, the entries in Book-keeping rose from 10,099 in 1919 to 16,617 this year.

The number of candidates who competed for the *Daily Sketch* Prizes was 1141, divided up as follows:—In Stage I., 560; in Stage II., 389; in Stage III., 192. In the Elementary Stage the prizes will be awarded on the results of the ordinary examinations in March and May last; but in the Intermediate and Advanced Stages candidates selected on the results of these examinations will be required to undergo a further test later on. Full particulars of the competition will be given in the usual detailed report on the examinations which will appear in the *Journal* in the autumn.

The liberality of the Worshipful Company of Clothworkers has enabled the Council, as in past years, to offer the usual silver and bronze medals. These medals are very highly valued by the successful candidates, and there can be no doubt that they contribute not a little to maintain the high standard of the examinations.

The results of the First Division of the Examinations, held in March, have already been communicated to the candidates; and those of the May Division will be announced as soon as possible.

In order to ensure that the Examinations should be kept in close touch with present-day requirements, the Council re-constituted the Examinations Committee, with a view to securing upon it fair representation of Local Education Authorities and of the teaching profession. This Committee has been engaged for some time in revising the syllabuses, and the greater part of this work has now been completed.

XI.—Viva Voce Examinations in Modern Languages.

Up to the present date fourteen examinations in French, German, and Spanish have been held this year in London, Coventry, Liverpool, York, and Manchester.

At these examinations 319 candidates presented themselves, of whom 235 passed (65 with distinction) and 84 failed.

Other examinations have been arranged in French, Italian, Spanish, and Russian.

XII.—New Council.

The Vice-Presidents retiring under the ordinary regulations are Sir Walter Egerton, Lord Islington, Sir Philip Magnus, Lord Sanderson, and Mr. Alan A. Campbell Swinton (the last of whom is nominated as a Treasurer). In their places the Council recommend Viscount Cowdray, Mr. Edward Dent, the Hon. Richard Clere Parsons, Sir Marcus Samuel, and Mr. Carmichael Thomas, all of whom have served on the Council in former years.

The four Ordinary Members of Council retiring are Sir Charles Carrick Allom, Mr. Edward Dent, Sir E. H. Tennyson-d'Eyncourt, and Dr. Martin Onslow Forster. In their places the Council recommend Mr. Charles Frederick Cross, Viscount Elveden, Mr. Charles B. L. Tennyson, and Sir Richard Vassar Vassar-

* See *Journal*, Vol. LXVII. p. 570.

† Particulars of the competition were published in the *Journal*, Vol. LVII. p. 611.

Smith, none of whom have yet served on the Council.

XIII.—Obituary.

The number of distinguished Fellows whom the Society has lost during the past twelve months is fortunately smaller than usual.

Earl Brassey, who was killed by being run over by a taxi-cab, was only elected a Fellow of the Society in 1918, but his father, the first earl, had served on the Council for some forty years.

Sir Percy Sanderson was a brother of Lord Sanderson, who was Chairman of the Council from 1911–13.

Mr. J. D. Crace had been a member since 1862, and frequently attended meetings of the Society.

Sir John Jackson had been a member of the Society since 1889.

Among other notable Fellows who have died during the last twelve months may be mentioned, Sir Alexander Baird, Mr. Alexander Izat, Admiral Charles John Rowley, Mr. Henry Gribble Turner, Mr. Albert E. Reed, Mr. Hennen Jennings, and Dr. Theodore N. Vail.

XIV.—Finance.

In accordance with Section 40 of the Society's By-laws, the Financial Statement for the year 1919 was published in the *Journal* of June 25th. This shows that the excess of expenditure over income for the year amounts to £621 11*s*. 8*d*. The deficiency is mainly due to the increased cost of the *Journal*, which rose from £2,131 6*s*. 1*d*. in 1918 to £2,851 11*s*. 10*d*. in 1919.* Office expenses have also risen from £3,558 9*s*. 4*d*. in 1918 to £3,870 6*s*. 8*d*. in 1919. On the other hand, there has been a satisfactory increase in the amount received in subscriptions—£6,261 14*s*. in 1919, as compared with £5,780 11*s*. in 1918.

Unfortunately there is no prospect of any diminution in the cost of the *Journal*. On the contrary, it seems likely that it will rise to at least £3,800 for the current year. In these circumstances the Council cannot but view the financial position of the Society in the near future with serious concern, and they have reluctantly come to the conclusion that it is necessary to raise the annual subscription from two to three guineas, and the life composition fee from twenty to thirty guineas.

Another matter which has been engaging their anxious attention is the tenure of the Society's House. The lease granted in 1775 by the Brothers Adam, after being twice renewed, came to an end in 1904, since when the Society has held the premises on a tenancy terminable by either side at two years' notice. The present landlord has served the Council with a notice terminating their tenancy as from March 25th, 1922, but he has expressed his willingness to sell them the freehold. The Council are strongly of opinion that every effort should be made to secure permanent possession of the historic house which was built for the Society by the Brothers Adam, and in which its work has been carried on for nearly a century and a half.

The Council have been earnestly considering this most important question, and they hope very soon to be able to submit to the Fellows some suggestions which they trust may meet with their approval and support.

* The cost of the *Journal* in the last year before the war, 1913–14, was £1,767 4*s*. 11*d*., when it contained 1055 pages, as compared with 810 pages in 1918-19.

The Chairman (Sir Henry Trueman Wood) moved the adoption of the report. He felt sure the Fellows must admit that, taking existing conditions into account, the report was really extremely satisfactory. The Society, like all other similar Institutions, had suffered, and was still suffering from the effect of the hard times. There was much more it could have done, if it had had sufficient funds, but the Society's resources had been sadly cramped, and the Council had been obliged to consider how those resources could be increased. The papers read at the Ordinary Meetings and in the Indian and Colonial Sections would compare very favourably with those of any previous Session, and as he had had to deal with the papers for so many years, he thought they would admit he had some right to speak on the subject. He thought the Society was to be congratulated on the programme of meetings and lectures, and upon the way in which the work had been carried out. With regard to the award of the Albert Medal to Professor A. A. Michelson, he was quite certain that the candidate selected by the Council, with the approval of H.R.H. the President, well deserved to be included in the list of very distinguished recipients of the medal. The value of Professor Michelson's work was universally acknowledged. It was, of course, more valuable from the purely scientific side, but it was also a very important contribution to Arts, Manufactures, and Commerce. He referred to the work of the examinations which the Society had carried on since 1856, and which had gradually grown both in amount and in importance. The Society had spent a good deal of money on the examinations. It never expected to make any profit out of them, and whenever there was a little profit, it had always been used for further extending and improving the examinations themselves. The tide this year seemed to have turned, and he thought it was only reasonable that

some of the profit should be devoted to the general purposes of the Society. There would also be some additional expenditure on the examinations in order to increase the fees paid to the Examiners, which were fixed many years ago, and were naturally insufficient with the present depreciated value of money. There was one other matter to which he thought reference should be made, and that was the question of the Society's premises. As stated in the report, the lease granted by the Brothers Adam in 1775, after being twice renewed, came to an end in 1904. The Society's former landlord, the late Mr. George Drummond, was unwilling to bind himself to renew the lease, and the Society had held the premises on a tenancy terminable on either side at two years' notice. The present landlord, Mr. G. H. Drummond, had served the Council with a notice to terminate their tenancy as from March 25th, 1922, but he had offered to sell the Society the freehold. The matter had been before the Council and before a Special Committee of the Council, and although he was not yet in a position to make any public announcement, he thought he might be allowed to say that several past and present members of the Council had promised very liberal donations to start a fund to enable the Society to purchase the freehold; and if the Council received sufficient promises of support, they proposed to appeal generally to the Fellows, and to ask them to subscribe to a fund so that the Society might still remain in the historic house in which it had done very nearly the whole of its work. He said he would defer what other remarks he had to make on the matter of the Society's finances until they came to the question of the motion relating to the increase in the subscription.

Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., said he had great pleasure in seconding the motion that the report be adopted.

The adoption of the report was then agreed to.

The Chairman said the next business was the proposal to increase the subscription of the Fellows from two guineas to three guineas per annum, and that the matter might be put entirely in order he called upon the Secretary to read the Resolutions of the Council as given in the notice convening the meeting.

The Secretary then read the following resolutions:—

1. That By-Law No. 56, relating to the annual subscription of members be altered and amended by the substitution of the word *Three* for the word *Two*.
2. That By-Law No. 59, relating to Life Compositions, be altered and amended by the substitution of the word *Thirty* for the word *Twenty*.

[The By-Laws, as amended, will read as follows:—

By-Law 56.—"The Annual Subscription of every member shall be *Three* guineas at least."

By-Law 59.—"Any member may commute or compound for all future payments, and become a member for Life, by payment of a sum of not less than *Thirty* guineas."]

The Chairman thought it was unnecessary for him to go very far into the financial question, for it was quite certain that the Society could not continue with its present resources. It might perhaps carry on for a certain time by utilising the resources it had accumulated in more prosperous times, but these would speedily be exhausted, and the Society would then be stranded. The Council had given very careful consideration to the matter, and they had come to the conclusion that it was necessary to raise the subscription. They all knew the depreciated value of money, and the purchasing power of three guineas now was certainly not equivalent to two guineas in 1914, and very far from what it was in 1754 when the Society was established. One of the heaviest items of expenditure was the cost of printing the *Journal*, which had risen from £1,767 in 1914 to £2,851 in 1919, and which would certainly reach £3,800 for the current year. It would therefore be seen that more than half the total amount of the annual subscriptions received from Fellows was expended on printing the *Journal*. The balance was insufficient to carry on the work of the Society, and he did not think it was necessary for him to impress upon Fellows the absolute necessity for making the alteration. The Council felt there was no alternative but to raise the amount of the subscription. The British Association had had to raise the subscription of their members, and he believed other societies contemplated doing the same.

Professor J. M. Thomson, F.R.S., mentioned that other learned societies, including the Linnean Society and the Chemical Society, had increased their subscriptions.

The Chairman then formally proposed the two resolutions.

Mr. Alan A. Campbell Swinton, F.R.S., said he had much pleasure in seconding the resolutions.

The resolutions were then put to the meeting and carried without any dissentients.

The Chairman proposed a cordial vote of thanks to the Secretary (Mr. G. K. Menzies) and to the other officers of the Society. It gave him great pleasure, he said, to propose a vote of thanks to his own successor, because from his long connection with the Society, he knew what the duties of the Secretary were better than anybody else, and it was a source of great satisfaction to see how extremely well the work had been carried on. The Society, he thought, was greatly indebted to the Secretary, and to the staff who had admirably supported him. Mr. Digby had been Secretary of the Indian and Colonial Sections for a long time, and during the past three years he had helped Mr. Menzies in the secretarial

duties. He thought they all thoroughly appreciated the admirable work Mr. Digby had done for the Indian and Colonial Sections, and the care and attention he had devoted to the general work of the Society. He had already referred to the examinations and the increase of work involved by their development. All this work had been admirably carried on, under the general superintendence of the Secretary, by Mr. Buchanan and his assistants, Mr. Cassidy and Mr. Toye, to all of whom great credit was due.

MR. CARMICHAEL THOMAS had very much pleasure in seconding the motion.

THE SECRETARY (Mr. G. K. Menzies) returned thanks for this expression of confidence in himself and in the other officers of the Society. He also wished to express his gratitude to Sir Henry Trueman Wood for the training he had received under him, and for the kind help and advice he had so readily given him since he took up the Secretaryship of the Society.

The ballot having remained open for half an hour, and the scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. [The names in *italics* are those of Fellows who have not, during the past year, filled the office to which they have been elected.]

PRESIDENT.

H.R.H. The Duke of Connaught and Strathearn, K.G.

VICE-PRESIDENTS.

Lord Askwith, K.C.B., D.C.L.
Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I.
Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Sir George T. Beilby, LL.D., F.R.S.
Lord Blyth.
Thomas Jewell Bennett, C.I.E., M.P.
Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.
Viscount Cowdray.
Sir William Henry Davison, K.B.E., D.L., M.P.
Edward Dent, M.A.
Peter MacIntyre Evans, M.A., LL.D.
Sir Robert Abbott Hadfield, Bt., D.Sc., D.Met., F.R.S.
Field-Marshal Earl Haig, K.T., G.C.B., O.M., G.C.V.O., K.C.I.E.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Lord Leverhulme.
Major-General Sir Desmond D. T. O'Callaghan, R.A., K.C.V.O.
Major Sir Francis Grant Ogilvie, C.B., LL.D.
Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
Hon. Richard Clere Parsons, M.A.
Sir Marcus Samuel, Bt.
Carmichael Thomas.
Sir Aston Webb, K.C.V.O., C.B., P.R.A.
Sir Henry Trueman Wood, M.A.

ORDINARY MEMBERS OF COUNCIL.

Charles Frederick Cross, F.R.S.
Viscount Elveden, C.B., C.M.G., M.P.
John Somerville Highfield, M.Inst.C.E., M.I.E.E.
Sir Herbert Jackson, K.B.E., F.R.S.
Major Sir Edward Humphrey Manisty Leggett, R.E., D.S.O.
Major Percy A. MacMahon, R.A., LL.D., D.Sc., F.R.S.
John Slater, F.R.I.B.A.
Charles B. L. Tennyson, C.M.G.
Professor John Millar Thomson, LL.D., F.R.S.
Sir Richard Vassar Vassar-Smith, Bt., D.L.
John Augustus Voelcker, M.A., Ph.D., F.I.C.
Sir Frank Warner, K.B.E.

TREASURERS.

William Henry Maw, LL.D., M.Inst.C.E.
Alan A. Campbell Swinton, F.R.S.

SECRETARY.

George Kenneth Menzies, M.A.

On the motion of the CHAIRMAN, a vote of thanks to the scrutineers was carried unanimously.

MR. ALAN A. CAMPBELL SWINTON, F.R.S., proposed a very hearty vote of thanks to Sir Henry Trueman Wood, not only for his conduct in the chair that day but for the large amount of time and trouble he had devoted to the affairs of the Society during his tenure of office as Chairman of the Council. He felt sure it was a great gratification to everyone belonging to the Society when Sir Henry Wood consented to become Chairman of the Council. They all knew the immense amount of time and trouble he had devoted to the Society. If there was any possible doubt as to the necessity of the resolutions they had just passed with regard to increasing the subscription—a course which the trend of events had rendered absolutely necessary—the fact that the matter was put forward by Sir Henry himself would, he thought, be sufficient to remove any such doubt in their minds, as they knew Sir Henry would only recommend what was in the best interests of the Society.

MR. JULIUS GARRATT had great pleasure in seconding the vote of thanks to the Chairman. Speaking as a provincial Fellow, he said that the name of Sir Henry Trueman Wood was a household word throughout the country.

THE CHAIRMAN, in acknowledging the vote of thanks, said it was a source of great gratification to serve as Chairman of the Council, and to hold the highest office in the Society, next to that of the President, which the Society could bestow upon any of its Fellows; and he expressed his thanks to all his colleagues for the way in which they had supported him. He said he had spent a very pleasant year of office, and he hoped still to remain on the Council.

The meeting then adjourned.

OBITUARY.

Sir Shapoorji B. Broacha.—The death of Sir Shapoorji Burjorji Broacha, the Bombay financier, has occurred in India. He did much to promote industrial development in the Western Presidency and elsewhere, and was equally distinguished as a philanthropist. His benefactions, public and private, were manifold, and included the gift of a new town hall to his birthplace—Broach—where a marble statue has been erected in his honour. Knighted in 1911, he served as Sheriff of Bombay, and was a member of the Royal Commission appointed in 1913, under the chairmanship of Mr. Austen Chamberlain, to investigate the Indian currency system. He joined the Royal Society of Arts ten years ago, and contributed a handsome sum to the Sir George Birdwood Memorial Lecture Fund. Throughout a long and honourable business career he enjoyed the respect and esteem not only of his own people, the Parsi community, but of all classes, Indian and European.

GENERAL NOTES.

Institut International du Froid. — An International Conference of Refrigeration, at which forty-two Governments, States, Dominions and Colonies were represented, was held in Paris, on June 21st, the French Minister of Agriculture, M. Ricard, presiding. The object of this Conference was the signing of a Convention which creates an International Institute of Refrigeration in Paris, supported by annual subsidies from all participant States. The aim of the Institute is to stimulate the progress of the science and technics of refrigeration, and to realise, for the benefit of all humanity, the development of the various and innumerable applications of refrigeration, which play so large a part in the economy of the world. The Executive Committee of the Institut is presided over by M. André Lebon, chairman, who is assisted in his work by vice-presidents and officers, elected among the representatives of the different powers in Paris. The Director of the Institute (9, Avenue Carnot, Paris) is M. Emile Gouault.

Accounts of Chippendale, Haig & Co.—The Victoria and Albert Museum have published in pamphlet form (price 2*s*.) the accounts of the firm of Chippendale, Haig & Co., for furnishing David Garrick's house in the Adelphi. For one who made such a mark in the development of furniture extraordinarily little is known about Chippendale. He came from Worcester with his father before 1727, occupied workshops successively in Conduit Street, Long Acre, and St. Martin's Lane, and was elected a member of the "Society for the Encouragement of Arts, Manufactures and Commerce"—and that is all concerning his private history that can be stated with certainty about him. The total cost of the furniture recorded in these accounts is £931 9*s*. 3½*d*. We have it on Dr. Johnson's authority that at this time Garrick lived as a prince rather than as an actor, "his table, his equipage, and manner of living are all most expensive and equal to those of a nobleman." We can therefore draw some interesting inferences as to the difference in the cost of furniture then and at the present day. The accounts give considerable details of the various articles of furniture supplied. "In the case of the drawing-room the walls were papered and finished with a gilt leaf border; fringed curtains of green silk damask hung at the windows and the same material covered the *bergères* and sofa, which were japanned green and yellow; two pier glasses were placed, no doubt, between the windows; and the scheme of arrangement was completed by a third mirror, two pembroke tables and three commodes of inlaid wood." The pamphlet will prove of great interest to the student of furniture.

Three Pile Figured Velvets. — Figured velvets having three distinct and separate heights of pile were invented by Sir Frank Warner in 1915 and patented by him in Great Britain, America and the leading textile countries of Europe. Figured velvets, in which the ground web was entirely covered with cut pile, the figure of the design standing up in higher pile, giving what is known as "pile on pile" effect, had been woven in Italy as far back as the fifteenth century. In the sixteenth century richer effects were obtained by the employment of gold or silver thread in addition to the pile on pile, and a further effect in the figuring was obtained by the use of uncut or looped velvet known as "Terry Velvet." In the latter half of the seventeenth century figured velvet weaving was introduced into England by the Huguenot refugees from France, and a fine example of their work is to be seen in the hangings on the Queen Anne bedstead at Hampton Court Palace. Before the end of the eighteenth century figured velvet weaving appears to have ceased in England, and it was not until 1875 that the art was revived by the late Benjamin Warner, the father of Sir Frank, who produced a fine example of velvet and terry on a satin ground. The design was by Owen Jones, and a specimen of it is now in the Victoria and Albert Museum. In 1908 Sir Frank Warner produced, for the first time in England, some pile on pile velvets, which were exhibited at the Franco-British Exhibition in that year. From that achievement arose the idea of producing the "three pile" velvet, in which the third height of pile forms a figure superimposed on another pile figure, which in its turn is above the first or ground pile. The expression "three pile" must not be confused with the old time term "three-pile" mentioned in several of Shakespeare's plays, which referred only to plain silk velvets then sold as one, two or three pile according to quality.

Journal of the Royal Society of Arts.

No. 3,529. VOL. LXVIII.

***All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.* (2)**

NOTICES.

INCREASE OF SUBSCRIPTION.

At the Annual General Meeting held on June 30th, it was unanimously resolved that the annual subscription of Fellows be increased from £2 2*s*. to £3 3*s*., and the Life Composition fee from £21 to £31 10*s*. The new scale will apply to all subscriptions due on and after Michaelmas, 1920.

These changes have been necessitated mainly by the great increase in the cost of the *Journal*, which rose from £1,767 4*s*. 11*d*. in 1913-14 (the last year before the war) to £2,851 11*s*. 10*d*. in 1919, and will probably rise further to about £3,800 for the current year. The general costs of maintenance and of conducting the work of the Society have also inevitably risen. Further particulars as to the financial position of the Society were published in the report of the Annual General Meeting in the *Journal* of July 2nd.

INDIAN SECTION.

A meeting of the Indian Section Committee was held on Monday, July 5th. Present:—

Sir Charles S. Bayley, G.C.I.E., K.C.S.I. (Chairman of the Section); Sir Charles H. Armstrong; Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.; Lieut.-Col. Sir Charles H. Bedford, LL.D., D.Sc., M.D.; Sir M. M. Bhownaggree, K.C.I.E.; D. T. Chadwick, I.C.S.; Sir Valentine Chirol; Laurence Currie, M.A., J.P.; W. Coldstream, B.A.; Sir Krishna Govinda Gupta, K.C.S.I.; Sir Henry Evan M. James, K.C.I.E., C.S.I.; Major-General Beresford Lovett, C.B., C.S.I.; Sir Charles C. McLeod; and Colonel Sir A. Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., with G. K. Menzies, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Indian and Colonial Sections).

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, May 20th, 1920; Lieut.-General Sir Herbert V. Cox, K.C.B., K.C.M.G., C.S.I., Military Secretary, India Office, in the chair.

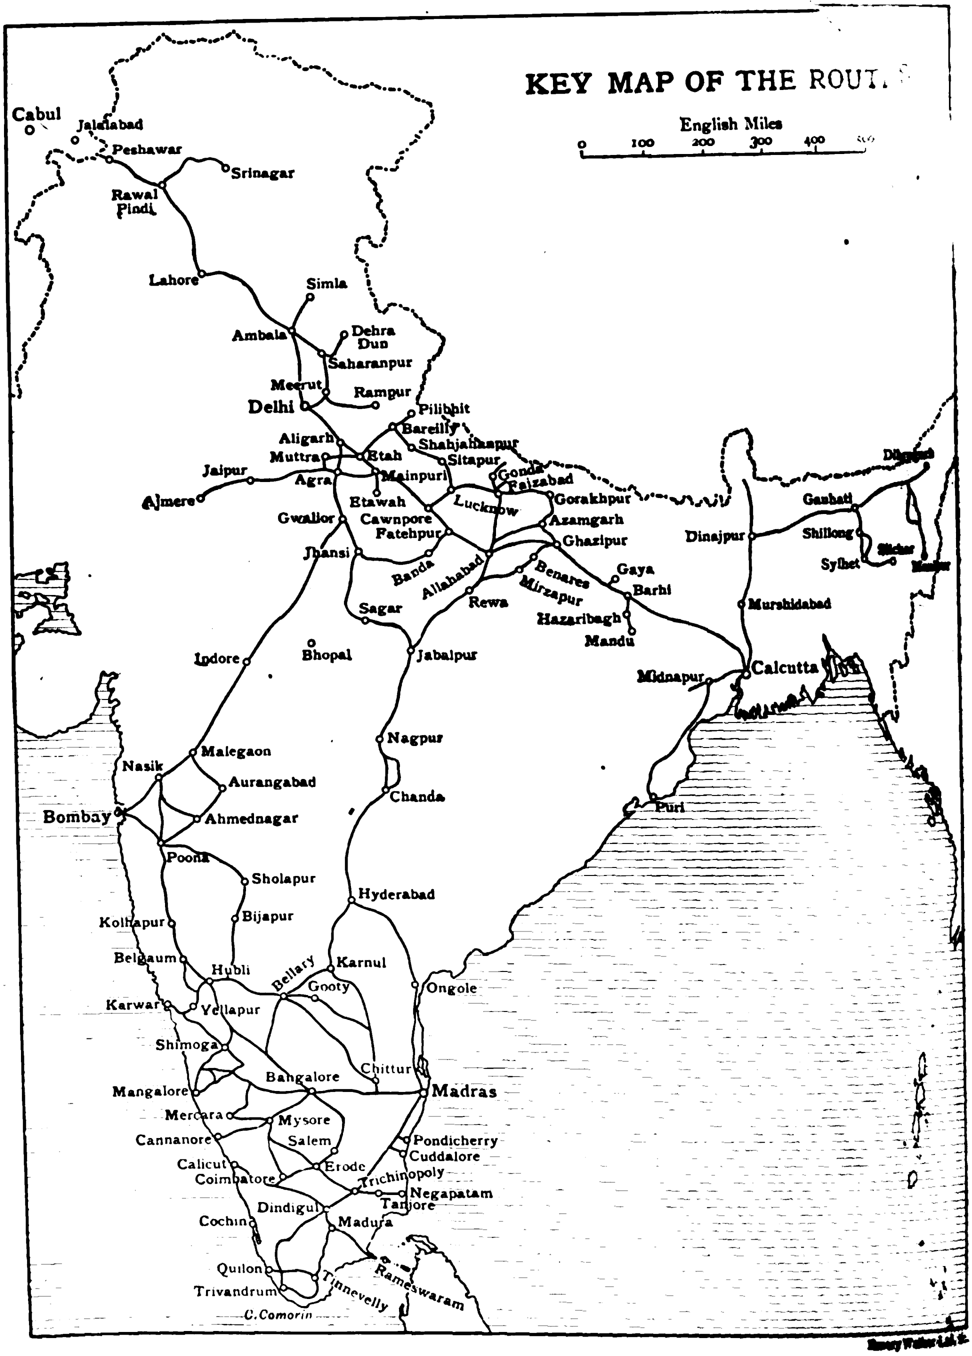
The paper read was—

ROADS AND MOTOR TRANSPORT IN INDIA.

By Brigadier-General Lord Montagu of Beaulieu, K.C.I.E., C.S.I.,

Adviser on Mechanical Transport Services in India, 1915-19.

In India, as in many other countries, the chief roads were originally made for military operations. I can trace no records of any definite road system previous to the occupation of certain parts of India by the East India Company. But through the greater part of India towns and populous districts must have been connected by tracks or kutcha roads for centuries, though no efforts seem to have been made to make them fit for continuous wheel traffic. It is probable that up to the first British connection with India the habitual means of transport was by means of coolies and animals, carrying loads on their heads and backs. The most ancient of all permanent roads in India are to be found on the Northern Frontiers, where, in more than one place, there are traces of Buddhist roads. These mountain paths were not blasted out of the rock, as would have been the case to-day, but burnt out by a peculiar process. Such a road is clearly seen over the Malakand Pass, below the present military road on the western slope, and it is interesting to recall the methods which the Buddhists adopted in order to make these roads. They lit wood fires upon the rock, mostly of a limestone character, and having made it very hot, suddenly poured water upon it, causing the stone to crack, and in this way laboriously achieved a more or less flat path on the mountain side. It is noticeable from an engineering point of view how well these old roads were made, showing that the constructors of those days had among them engineers of practical, if not of theoretical, experience.

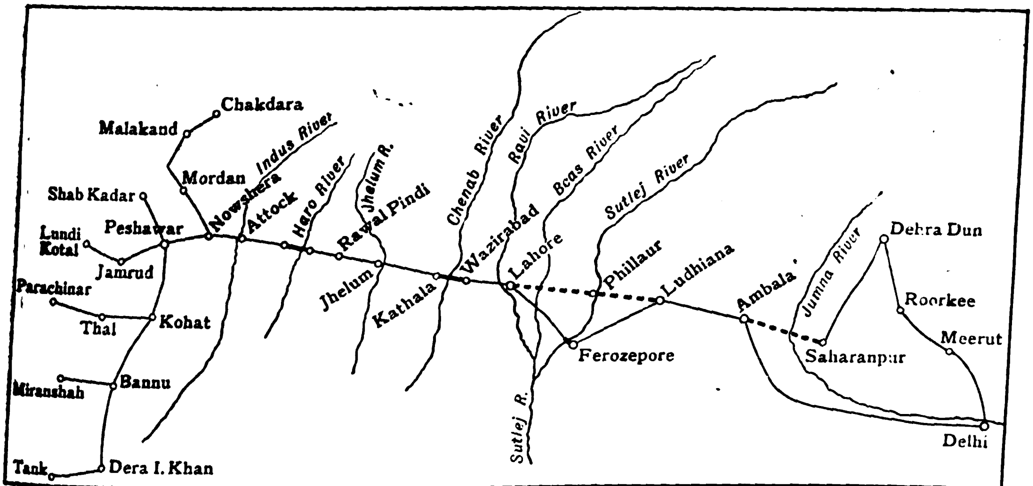


The first attempt at a national road system began with the construction of the Grand Trunk Road in 1839. At first this road commenced at Fort William, Calcutta, and extended westward to Cawnpore, thence on towards Ambala and Lahore. From there it was extended later, mainly by John Nicholson, through Warizabad and Jhelum to Rawalpindi, and eventually past Attock to Peshawar. At the summit of the Mogalla Pass, some twelve miles west of Rawalpindi, there is a marble tablet to Nicholson, whose victories and road-making it commemorates. The Trunk Road between Calcutta and Peshawar is 1,490 miles in length. When it was in good order it was probably the longest continuous stretch of properly engineered and well-laid road in the world. Other road systems, formerly in good order,

still remain in places, notably the road from Bombay through Indore and Agra to Delhi. Another road, now derelict, left the Grand Trunk Road at Benares and went through Rewah and Jubbulpore to Nagpur and Hyderabad, and thence through the Nizam's dominions on to Madras. To-day the greater part of this road is a mere track or at best a bad kutcha road. When at Secunderabad in the spring of 1915, I explored most of the so-called main roads in the Nizam's dominions, and found that beyond a short radius from Hyderabad they were impassable for mechanical transport, and had become second-class kutcha roads.

From an old map which I have here, dated 1853, and published by Messrs. H. Allen & Co., of Leadenhall Street, it will be seen that there are no railways marked, but many more roads than would appear on any map nowadays. Only a few of these roads are traceable to-day as existing main trunk roads. The majority of them have disappeared, or at any rate have become kutcha roads, only usable by local traffic. main roads all over India. To-day, however, compared with the area of the country, the number of its inhabitants, and the importance of its commerce, India has probably fewer miles of good road than almost any other civilised country in the world. I do not wish upon this occasion to touch in any way upon controversial subjects, but I think I may say that a comprehensive road policy for India has become an urgent need, in regard not only to the present, but the future development of India.

When railways were first made in India, there was at once a marked decline in the interest taken in and the money spent on roads by the Government of India and Native States alike. At that time, so much were the railways thought to be going to take the place of roads for ever, and render them unnecessary, that in some places, notably on the Grand Trunk Road between Lahore and Peshawar, the railway was actually built on the surface of the Grand Trunk Road itself, and no provision was made for the continuity of the older highway. In one case



Emery Walker Ltd. sc.

But the number and extent of these roads in 1853, nearly seventy years ago, is a probable indication of how the road system of India suffered from the coming of the railway.

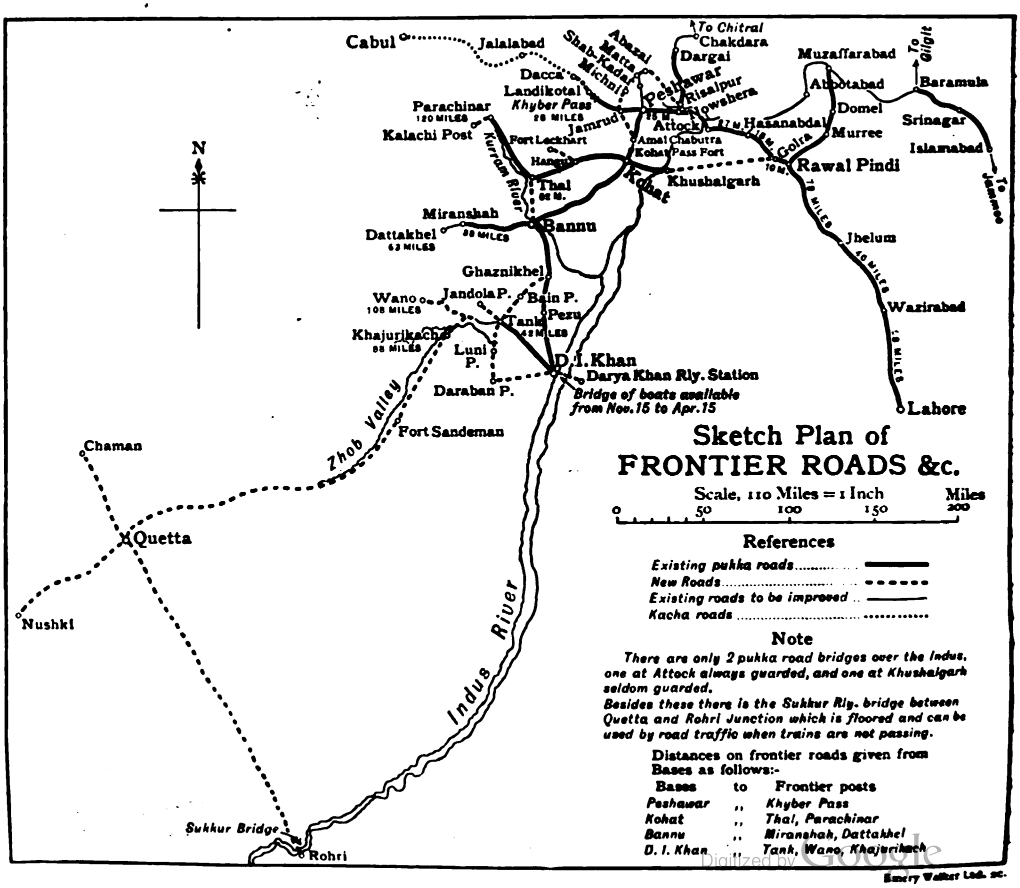
Madras, as is well known, is the oldest province in India, and it is interesting to note that to-day, as formerly, the road systems of Madras and Southern India are more highly developed, and there are more roads per square mile of country and per head of population than in any other part of India. What the road systems of India might have become had not the railway era in 1853-60 supervened, it is not easy to say. Probably there would have been thousands of miles of first-class the actual arches which formed part of the bridge of the Grand Trunk Road between Kathala and Wazirabad were used for the permanent way, and it was only in the spring of 1919—after I had constantly brought the matter to the notice of the Government of India for three years, that an effort was made to restore this gap, one of many, in this great Indian highway. I hope that the new road-bridge over the Chenab at that point will be completed before long. There are other instances where the road-bridge having collapsed, no steps were taken to repair it, and the roadway was taken over the railway bridge, as was lately the case of the Haro River, between Rawal-

pindi and Attock, where the road and railway used the same bridge, a dangerous combination from a military point of view. A new bridge was built here in 1918–19. Every means of transport up to twenty years ago was held to be subservient to railways, but the more enlightened railway authorities to-day recognise roads as the most useful allies of railways, and the abandonment or destruction of roads for railway purposes will probably not occur again.

As regards the North-West Frontier, where roads are vital from a military point of view, these roads were and are being built and maintained mainly out of military funds. The extension and improvement of these roads have been rendered increasingly necessary by the constant frontier wars which are apt to break out from time to time on the frontier between Quetta and Chitral. It is only, however, during the past four or five years that most of these roads have been made fit to bear mechanical traffic. In some cases new roads have been built to supplement the older highways, notably in the case of the Khyber Pass, where at last a proper alternative road has recently been constructed. There has been a second road up the Khyber, mainly used by animal traffic, for a long time past, part of which was also used by wheeled traffic. Formerly part of this road ran along the bed of a nullah and was therefore liable to be swept away by floods; but now the new road is sufficiently high above [illegible] to be immune from damage from floods. In the case of the Khyber, there has also been constructed of late a wire ropeway which should relieve the strain on the roads in the Pass in case of further military operations. I hope we shall soon see more ropeways in operation, notably up to Murree, and over the Malakand.

Frontier roads, to take them in order from north to south, are as follows :—

1. From Abbottabad through the Batrasi Reserve to the Kashmir frontier.
2. From Nowshera to the Malakand and Chakdara.
3. The twin Khyber Pass roads.
4. The Peshawar–Kohat road.
5. The Kohat–Thal–Parachinar road.
6. The Tochi Valley road.
7. The Gumal–Tank road.
8. The Kohat–Bannu–D.I.K. road.
9. The roads in the Peshawar Plain to Shab Kadar.



Some of these roads have now been made more or less pukka, and should be able to bear the ordinary military traffic which is carried on mainly by means of mechanical transport. There are other roads under construction or consideration, such as the Thal–Spinwam–Idak road, the extension of the Tochi road further up the valley past Datta Khel, of the Tank road by Kirghi towards Jandola, and of the Gumal Valley road towards Fort Sandeman and Quetta. The policy of peaceful penetration by road-making has proved its value over and over again, and is now recognised as a cheaper and more effective way of keeping order and stimulating civilisation on the frontier, than military expeditions from time to time. I respectfully suggest, therefore, to the Government of India and to the India Office that a progressive and well-thought-out road policy on the frontier is the best antidote for small but expensive wars there, and should troubles occur of a graver kind, of the greatest possible assistance to the military forces who have to be employed.

With regard to the rest of the roads of India outside the Punjab and the North-Western Frontier, the subject is so huge that I cannot do more than touch upon it in a very general sense. Till lately the importance of roads has in many parts, I am afraid, been lost sight of by successive administrations in India. Besides abandoned roads, and broken bridges to be seen all over India, on what were once much-used main roads, the spectacle can here and there be seen of irrigation colonies growing heavy crops, having been laid out in the most approved style, but with insuffi ient allowance in the plan for roads along which the produce can easily be transported to the local market, the railway, canal or pukka road. Very primitive and expensive methods of transportation therefore have been used, and disputes constantly arise as to pack animals treading down crops on lands of people other than their owners, and the canal banks, notwithstanding the efforts of the canal officers, are almost invariably used as highways instead of roads for a large portion of the traffic of the district. Wherever irrigation colonies or settlements are instituted in future it should be laid down by the Government of India that adequate roads must be made providing for proper communication between every part of the area irrigated or settled, as a *sine qua non* of the scheme. In some cases it might be well to combine the land reserved for roads with a provision for light railways as well. Over rivers and canals where there is no question of military importance, combined road and railway bridges should be adopted. It is interesting in this connection to record that one of the greatest difficulties in India which is met with when country districts are affected by famine has hitherto been the lack of facilities for moving food even when the food was available near by. It is probably no exaggeration to say that millions of human beings have died in India during the last fifty years, not so much because there was a lack of food within reasonable distance, but because of the difficulties of transporting that food into the districts affected. With a better system of roads and transport this difficulty would be largely removed. With the present railway system aided by an extension of roads, the alleviation of famine conditions in future should be possible with much greater certainty, economy, and ease, especially as it is very rarely that shortage of food exists all over India at the same time.

As regards the road metal available for use on roads in India, in a continent of such vast size the material nearest to the particular road in question is nearly always used. All round the North-West Frontier Provinces fairly good road metal, mainly of a limestone character, is obtainable from the surrounding hills. In the Eastern Punjab and United Provinces, what is called kanka is largely used—a kind of soft limestone which, however, makes a very fair road if the traffic upon it is not of too heavy a nature. There are also roads and road foundations to be found in India, where stone is not available, made of burnt brick. In the Deccan and parts of Central India, stone of granitic origin is available, as also in the neighbourhood of the Nilghiris. But over most of the south of India and in most parts of the Gangetic and Indus plains, good stone is difficult to obtain, and can only be brought from a distance, an expensive operation, and in the congested state of Indian railways to-day difficult to arrange. In the Bombay Presidency, in the neighbourhood of the Ghauts, stone generally of a limestone or shale nature is used, and very fair roads are thus obtained. The greatest wear and tear on the surface of good roads in India is caused by the heavily loaded, narrow-tyred bullock-cart. The bearing surfaces upon the road of the wheels of these carts is often not more than an inch to an inch and a half in width, while the cart itself may be carrying upwards of a ton load on two of these wheels. This overloaded wheel produces a greater strain upon the road than the ordinary three-ton M.T.

vehicle or the Indian standard lorry, which fully loaded, weighs only $6\frac{1}{2}$ tons, but with a bearing surface of rubber on the hind wheels of about eight inches, and on the front wheels of about four inches in width, causing a less strain on the roads than the bullock-cart. I have suggested on more than one occasion to the Government of India that regulations should be made that after a certain date, say, two years, from the date of the proclamation, time sufficient to carry out any alterations required, there should be a progressively heavy tax upon all animal-drawn carts whose tyres do not conform to a certain standard to be laid down, say a minimum width of four inches. Not only would a certain amount of revenue be derived from such a tax available for road upkeep, but a large amount would be saved annually in repairs to the roads, and a broader wheel would tend to consolidate and not to destroy the surfaces used. In connection with this question of narrow iron tyres, it is interesting to note in the case of the New Forest in Hampshire that such a regulation was made some years ago, jointly by the Crown and the local timber owners, and an immediate recovery in the ordinary secondary roads of the district was at once noticed. The local timber haulers now prefer the broader wheel, and the roads are also saved much unnecessary wear and tear. As regards any new roads made in India, especially on the frontier, a toll system might be instituted and some direct revenue raised from the users of the road for its use.

It may be asked what should be the policy of the Government of India with regard to the future administration of the roads. I would respectfully suggest that what is wanted in India first of all is a classification of existing roads in order of importance. They should be divided into first and second-class pukka roads, and third-class or kutcha roads. All roads of national and military importance should be placed in the first class, and should be maintained by the Government of India irrespective of provincial governments, but possibly with a contribution from them for the local use made of them. Such typical roads would be the main line of the Grand Trunk Road from Calcutta to Peshawar and from Bombay towards Delhi. Class 2 should be pukka roads of provincial but not necessarily of national or military importance. These should be under the control of and be repaired by the provincial Governments of Madras, Bombay and Bengal. The third classification would consist of roads of comparatively little national or provincial importance, but necessary for local use. Some of these might be made pukka, but the majority would probably remain kutcha. It should be the declared policy of the Government of India to bring up as soon as possible the surface of the third-class road into the first or second class between all important towns. A permanent department to deal with roads should also be instituted by the Government, which need not be on the ambitious and expensive scale of the Ministry of Transport recently instituted here, but have a modest beginning with a director, one or two assistant directors, and say half a dozen officials in various parts of India to carry out the duties of correspondence and local supervision.

Since April, 1915, when the Government of India first decided to possess its own mechanical transport, the number of personnel and vehicles have increased with every year, till at the end of 1919 there were something like 5,000 personnel and about 4,000 mechanical transport vehicles under its administration, including the Ford vans and cars specially obtained for the Afghan war, and now in use on the frontier. The use of mechanical vehicles among the commercial community is also largely increasing, and in Bombay, Calcutta and other commercial centres, a large amount of goods is being conveyed by mechanical transport, which till a few years ago was moved solely by animal power. There has also been a great increase in the number of motor-cars used by both the British and Indian community, and the demand seems still unsatisfied. I may remark that purely European types, both of lorries and of ordinary motor-cars, are unsuitable for use in India during a considerable portion of the year owing to their having insufficiently large radiators. It is true that some European types continue to run, but they are operated at a disadvantage compared with those that have been specially designed to suit tropical conditions. It must be remembered that when the water in the radiator is constantly boiling, not only is there a serious decrease in power produced by the engine, but mechanical troubles tend to develop as the direct result of overheating. In my opinion there is a great future before any firm who cares to specialise in a tropical model for the private owner's car. As regards lorries, the Indian Standard $2\frac{1}{2}$-ton vehicle specially designed for tropical use, has already proved its worth, and is probably the best lorry for work in hot climates that has yet been designed.

As rega[illegible] traffic, everyone in India [illegible] the commonest vehicle on the ro[illegible] cart." It is in reality a [illegible] though cumbrous, [illegible] vehicle. [illegible] occasion I counted thirty-two huge [illegible] each weighing well over [illegible] loaded on one cart, the load of which [illegible] have been in the neighbourhood [illegible] tons. This weight was being drawn on [illegible] wheels by two oxen with comparative ease. [illegible]se bullock-carts are much better balanced by the drivers than is generally supposed, and the oxen, though at first sight they appear to be overladen and unable to cope with the load, yet manage to draw these heavy weights without much apparent trouble. In some cases where there are not even kutcha roads, pack animals are, of course, still used, and on the frontiers the strings of camels called "kafilas," winding down the passes from Central Asia, are a characteristic feature in Northern India. Everything, in fact, from elephants to the most diminutive donkeys, are used by the people of the country for transport purposes.

There is one factor about the roads in India on which one cannot help remarking: that is the absolute lack so far of any effort to make them—some of the most dusty roads in the world—dustless. This is the case even in the neighbourhood of cantonments. Not only is dust a nuisance, but it is distinctly prejudicial to health, and in the case of many cantonments there is much expense incurred annually for watering, which is in itself destructive of the surface of the road. There is, for instance, no reason why the main roads of Delhi, Lahore, Rawalpindi, Peshawar, and other military camps and important centres should not be made entirely dustless, and I am convinced that the extra expense in tar-spraying or the use of tarred stone would be amply repaid by the increase in the life of the road. Then there are also cases on the frontier where dust in the summer and mud in the winter are great drawbacks to military operations. Here again, a dustless road with a bituminous surface would be of immense benefit to both troops and animals. In regard to the supply of tar, I have been unable to obtain any reliable statistics, but there should be enough tar made in various gas works all over India to provide a good many gallons for making roads dustless every year. If there are not existing plants for the distillation of tar from coal in the Bengal coalfields some could well be set up.

There are, of course, other aspects of Indian transport which hardly come within the scope of a paper on roads and transport, such as the railway systems, the traffic by sea and river, and the traffic which is animal-borne or drawn all over India. But I will touch for a moment very briefly on some of these points. As to the railways, it may be said that on the whole India has a very fair system, though there are too few lines for present needs. But the many differences of gauge are without doubt a very serious bar to the economical and efficient handling of traffic. There are at present, besides the standard gauge of 5 ft. 6 ins., the metre gauge of 3·3⅜, the 2 ft. 6 ins. gauge, and the 2 ft. gauge, making three gauges of less width than the standard gauge. It should surely have been possible to have had one standard narrow gauge as well as one standard broad gauge for railway purposes. India is also suffering from a lack of sufficiently powerful locomotives, and on most lines of rails of too light a weight on the permanent way, which make heavy locomotives impossible. But the most noticeable defect is to be found in the many weak bridges which span the rivers, great and small. There is hardly a railway company which dares run its trains at ordinary speed over the majority of these, and the constant slowing down every time a bridge of any size is approached causes serious loss of time and unnecessary wear and tear upon railway stock and the permanent way. There are even some bridges of first-class importance like the Sukkur Bridge over the Indus between Rohri and Ruk, which are by no means in a safe condition. Were this particular bridge to become permanently unusable, the whole of the Quetta district and country west of the Indus would be without any direct railway communication with the rest of India, except by a circuitous route *via* Hyderabad and Kotri. The average speed also of even the fastest mail trains is slow, as will be seen from the table (see p. 548) calculated on the speeds attained in 1919.

Before the war, these average speeds were slightly higher, but not worthy of great railway systems, mostly state-owned or controlled. The provision of accommodation also for travellers, especially third-class travellers, is poor compared with other countries. Local circumstances exist, however, which make the operation of railways more difficult than in temperate climates or European or American countries. There are many other aspects of railways in India and their working which deserve a separate paper, and for which I have no space here.

Mail Train Speeds, 1919.	Miles.	Hours.	M.P.H
1. *Bombay to Peshawar, viâ* Delhi—			
(*a*) G.I.P. and N.W.R.	1,542	55	23
(*b*) B.B. and C.I.R.	1,450	53	27½
2. *Bombay to Karachi, viâ* Baroda	992	46	21
3. *Bombay to Calcutta*—			
(*a*) E.I. and G.I.P.R.	1,349	43	31
(*b*) B.N. and G.I.P.R.	1,223	46	26½
4. *Bombay to Madras*	794	36	22
5. *Calcutta to Madras*	1,030	41	25
6. *Calcutta to Delhi*	903	28	32½
7. *Madras to Colombo*	700	35	20
8. *Madras to Jhansi Junction, viâ* Dhond and Manmad	1,314	64	20½

There are some military aspects in regard to the provision and maintenance of roads in India which should not be lost sight of, particularly in these disturbed times. Railways are no doubt a means by which troops can be conveyed more quickly and more easily than by any other method. But it must be remembered that railways can be interfered with or destroyed at any rate temporarily, and bridges blown up with comparative ease. Such interruptions and breakages can only be repaired after some time by railway engineers. However, so much has the Government of India come to rely solely on railways as the only means of communication, that even sections of the Grand Trunk Road, important from a military point of view, have been allowed to lapse into jungle or third-class kutcha road, and become unusable. To take an instance, the Grand Trunk Road from Ambala eastwards towards Saharanpur is now unusable, and were the local railway or bridges over any of the intervening rivers to be blown up, it would be difficult to move troops from Ambala eastwards or from Lucknow westwards without prolonged delay and the construction of temporary bridges and the provision of rafts and barges. A road, however, cannot be easily destroyed in the same way, and if destroyed can very soon be repaired. In my opinion roads are as important as railways from a military point of view, and to rely solely on railways in the case of moving troops in time of necessity is to rely on a calculation which may break down and cause the executive very serious trouble. I know that one of the stock objections to a progressive road policy in India has been that as the Government of India owns most of the railways, it should not encourage the public to use the roads and leave the railways. The attitude is, I am afraid, inevitable and natural in regard to state-owned concerns, when the military interests and those of the public clash with the interests of a revenue-producing department of the state. But in India many things besides mere revenue have to be considered. The maintenance of law and order and the easy movement of men and material in peace and war alike are of at least equal importance, and the loss of a few thousand passengers or tons of freight a year between certain towns in consequence of an improved system of road communication should not in my opinion be weighed in the balance.

The latest returns in 1901-2, now nearly twenty years ago, show that about 37,000 miles of metalled road, and 136,000 miles of unmetalled, or kutcha roads existed. The population of India is now about 320 millions, and the miles of road per head of population are therefore ridiculously few. From a military point of view the Government of India has lately begun to realise the growing importance of roads, the expenditure having been: 1917-18, Rs. 49,72,797; 1918-19. Rs. 77,21,588; and as estimated for 1919-20, Rs. 2,50,00,000.

The Imperial civil roads in 1917-18 cost Rs. 6,00,463, while the provincial civil roads cost Rs. 51,89,223, making a total of about 58 lakhs. This year more will doubtless be spent, but even if 100 lakhs are found for civil roads, the military expenditure will then still be two and a half times the civil expenditure, a difference neither easy to explain nor apparently justifiable, when one remembers the large excess of civil over military traffic on the Grand Trunk and other main roads in India. A large part of the military expenditure on roads benefits the civil population, and I venture to suggest that the proportion of civil compared with military expenditure needs further consideration by the Government of India.

It is sometimes forgotten that roads have

immense and continuous influence on the [illegible] life and civilisation of a nation. The free circulation of traffic like free circulation of the blood makes for health, whether national or physical. The existence of monuments of [illegible] the possession of palaces, [illegible] of grandeur and fame, are cherished by every nation and country [illegible] past and hopeful of its future. But [illegible] remains the daily means of life and [illegible] the highway of human birth, marriage [illegible] death, wonderful, ever unfinished, vital to every civilised nation. Let India look to it therefore, that her highways become worthy of her greatness.

DISCUSSION.

THE CHAIRMAN (Lieut.-General Sir Herbert V. Cox) was very glad indeed that the author had given frontier roads a prominent place in his most interesting paper, because they were surely the best means of carrying out the frontier policy of the country—namely, the civilisation and pacification of the troublesome borderland, and of enforcing our will upon recalcitrant tribes. There was a very pertinent case now in Waziristan. What might be called the main penetrating roads towards the front up the salients on the North-West Frontier had been very much improved of late years, and, generally speaking, were now fit for mechanical transport well up into what might be called the danger zone. There were many present who could remember the old days of the Afghan War. When he went out from Sandhurst and travelled to Afghanistan, at the beginning of 1880, the railhead was at Jhelum, which was then over two hundred miles from the danger zone, and the journey at that time had to be done in dak gharries or tongas through a troublesome part in those days. Some of the hills that ran across the grand trunk roads were full of dacoits, and he had a very vivid remembrance of sitting in a tonga with a pistol on his knees. It was an interesting contrast to note that less than three months ago he travelled from Kohat up the Kurrum Valley to Thal, a distance of sixty miles, in a Ford car, over a very excellently graded and surfaced road. Things changed slowly in the East, but they did change, as could be seen by looking back over a sufficient period. The author was perfectly right in saying that lateral roads connecting the main roads were very much wanted. There was no better simile to explain the frontier and its geography and its necessities than the open right hand knuckles upwards. The little finger might represent the salient going through Nowshera up through Murdan and the Malakand Pass and on to the Pamirs; the next salient was the Khyber and the main road into Afghanistan; the next one the Kurram and the route to Kotal; the next the Tochi, the main valley of Waziristan; and the last one, which might be represented by the thumb, well to the left, accurately described the Gumal and its connection with the valley towards Quetta. Everyone would have to come back almost to the back knuckle of the hand to get round to any of those points; in fact, in the case of Waziristan, to get to the Zhob Valley, one had to come back to the main lines of railway running along the banks of the Indus. That required to be bettered. As to the rest of the country, he quite agreed with the author that a system of classification of roads was required; in fact, he believed that was largely being done now. He was a little surprised that a great motorist like the author did not, when speaking about the wheels and the conditions of the roads, refer to the pernicious habit the byle cart people had, when they rested on the grand trunk road for the night, of stopping all their wheels with bits of rock or brick, which they invariably left for the next motorist to come up against. In driving on even the best of Indian roads the driver had to keep his attention solely on the surface of the roads, if he did not desire to find himself in the middle of a collection of stones and bricks. There was one point which should appeal especially to this Society, and that was the matter of tree-planting or re-afforesting along the roads of India. It should be much better and more systematically done than it was now. Intense heat prevailed for six or seven months of the year, and shade was a priceless boon to a traveller on the road. There were many beautiful trees suitable for roadside shade which were natural to India, such as the neem, the tamarisk, the mango, the peepul, and the bamboo; yet there were hundreds of miles of quite important roads without a single tree, and the traveller, man or animal, was exposed to the scorching direct rays of the Indian sun. Where planting had been ordered—and it had been ordered more often than people thought—it was so badly done that young trees had not had a chance. The lazy Public Works coolie put the trees in badly to begin with, and the rapacious contractor, whose business it was to build guards round the young trees, scamped his work and used few bricks and no mortar. The next arrival upon the scene was always those devastating country goats, driven by an irresponsible boy. The first goat butted the contractor's fence with his iron forehead, and then the whole of the goats trooped in and in a very short time the sapling had gone. The matter required more care and supervision than were given to it at the present time. Light railways had proved extremely valuable in feeding the main lines of rail and the main roads, and he would suggest that systems of kutcha feeder roads towards light railways and main roads

were much wanted in every Province, and particularly in Burma. Burma had its railway and the Irrawaddy running close to each other, but was very much wanting in feeder roads for both. Irrigation and railways had done much to relieve India of the dread of being devastated by famine on the scale of the olden times, but in these days of general shortage of food means of transportation were more important than ever, and should not be neglected in any part of the world. He quite agreed that India's roads were not at present worthy of her greatness, and he hoped that they might become so in the near future.

General Sir Edmund Barrow, G.C.B., G.C.S.I., said that many years ago he traversed nearly all the routes and passes leading from Peshawar and the Malakand to the Pamirs, and traces of Buddhist influence and culture were constantly visible in old roads, irrigation channels, and walls of defence. The natural frontier between this region and Peshawar was crossed at the Malakand, and eastward of that pass by several ancient lines of communication, which were extraordinarily well laid out with good gradients, and now, after twenty-five hundred years, were still usable in parts. He had been over several of those ancient roads and would in parts certainly prefer to walk by the old Buddhist road rather than the new one made in 1885. He very much deplored the neglect of roads generally in India to-day, which caused many difficulties in transport, and he could thoroughly endorse what had been said by the author as to the great need of good motor roads for Indian communications. With regard to the Thal-Idak road mentioned by Lord Montagu, it was a lateral road of the very greatest value. He did not know whether it had been put in really good motoring order yet, but traversing it many years ago he was convinced that there might be made an easy first-class road from Thal to Idak. Had there been such a road during the recent operations on the frontier, he had not the slightest doubt that those operations would have been greatly facilitated. Thal was the railhead and was within two marches of Idak by road, and a good cross road from Thal to Idak would greatly assist the defence of that part of the frontier, and possibly save the construction of more difficult roads penetrating Waziristan from other directions. About a century and a half ago Field-Marshal Wade entirely changed the aspect of affairs in the Scottish Highlands by the roads he made; up to that time the highlanders had given great trouble, but since then they had been one of the most important elements of the British Army. The Romans everywhere transformed the barbarous countries which they conquered mainly by the influence of the roads they constructed. The value of good roads in civilising countries was immense. The vast construction of railways in India had had a tremendous effect. He had constantly heard it urged by high authorities that the construction of those railways and the telegraphs made our position in India so secure that we could readily reduce the strength of our armies in India; but he ventured to think that that view was entirely erroneous, as railways were easily cut. Only last year communications were interrupted for several days around important centres such as Amritsar and Lahore. It was most important, therefore, from a political and military point of view that roads should be maintained as well as railways and telegraphs.

Sir William Joynson-Hicks, Bt., M.P., said that in travelling in India he had been struck with the extraordinary life of India on the Indian roads, and he almost came to the conclusion that the Indians lived on the roads; certainly they used them far more than roads were used in England. In this country it was possible to go miles and miles without meeting more than one or two farm carts, but in India the whole village life seemed to concentrate on the roads. Very often one was surprised to see a bedstead or grand piano apparently walking along on its own, with four or six pairs of legs of coolies underneath. Every country required good roads and plenty of them. With regard to the frontier, he supposed there was no one in the room who had been through the passes quite as recently as he had. In the last few weeks he had been through the Khyber to the Afghan frontier below Landi Kotal, through the Malakand to Chakdara, and through the Kohat. He was perfectly convinced—not because he knew anything about India, but because for years his life had consisted in finding out and classifying the opinions of other people—that the only way to get rid of frontier troubles was by an occupation of the frontier, and this could not be successfully carried out unless the number of roads was enormously increased. The question of a railway through the Khyber was of the most vital importance. Only on the previous day a high official of the Indian Government had told him that if he really wanted to "go for" the Government he should complain bitterly that for the last twenty years the great need had been for a railway through the Khyber. When talking to generals in the Khyber, they implored him to make every effort he possibly could to insist on the railway being carried through. When it was begun it should not be spoiled by making it a metre gauge. The broad gauge ran to Jamrud, and if the line was carried through the Khyber on a metre gauge there would be infinite trouble whenever any warlike operations had to take place. The railway was quite possible from an engineering point of view, and it was not much more costly to run a broad gauge than a metre gauge. There was no reason

why a railway should not run through the Malakand to Chakdara and by connecting those railways the turbulent tribes would be at the mercy of the British. In 1918, it was said, there were no less than 507 trans-frontier raids in the Province of Peshawar alone. As far as he could gather, the only way to stop that was the old Roman system of civilising by means of roads, and by the modern means of railways. He advocated taking the subsidies away from the tribes and giving the money to individuals in the shape of wages for building the railways. The tribes would get the same amount of money, and, instead of disloyalty, there would be an education in work which would turn the tribesmen into contented settlers The Swat Valley was almost civilised to-day through roads, irrigation, etc.

SIR GEORGE BUCHANAN, K.C I.E., M.Inst.C.E., said the Province in India he knew best, Burma—sometimes called the "Cinderella Province"—was supplied by nature with magnificent waterways—in fact, in Lower Burma they were the principal means of communication; but waterways, however good, must be backed up by roads and light railways, and there must be in addition to waterways through railway lines and roads. Further, as every engineer knew, waterways deteriorated and required supervision and maintenance. It was not, however, until 1919 that even a survey was made of the waterways, and in the matter of roads to all intents and purposes there were none worthy of the name. The British had been in Arracan and Tenasserim nearly a hundred years, and the former division with an area of 18,500 square miles possessed only 33½ miles of so-called roads. So long ago as 1886 Sir Harvey Adamson, ex-Lieutenant-Governor of Burma, then a district officer, wrote: "We have held Akyab for sixty years, during which time we have taken from the land a comparatively much heavier revenue than in other parts of Burma, and yet we may travel far and wide throughout the district without seeing indications of a single rupee ever having been spent for the improvement of the country, or the benefit of the people." In Tenasserim, with 36,000 square miles, there were until the War ten miles of metalled road, but the need of wolfram for war purposes speeded up matters, and within a year a good system of roads had been constructed in the Tavoy district, but the remainder of Tenasserim, with some of the finest rubber land in the world, and a great salt industry, remained without either roads or railways. All over Lower Burma skeleton bridges could be seen, the roads of which they at one time formed a part having disappeared, leaving the bridges as a monument to our administration. The recently issued report of a special committee which had sat for three years and went into the whole problem of communications, stated that the estimated capital expenditure to convert the existing tracks into a not very high standard of metalled road was £8,000,000, with a recurring expenditure for maintenance of a million pounds a year. No comprehensive scheme for new roads was drawn up, as such would have been a waste of time. The total mileage of railways in Burma was only 1,600 miles, and it was not too much to say that £10,000,000 could be usefully spent on profitable railway lines at the present time, in addition to a comprehensive road programme. As a result of his experience he fully subscribed to all Lord Montagu had said as to the vital necessity for adopting a comprehensive programme of road construction in India and Burma. He congratulated Sir William Joynson-Hicks on his happy experiences when travelling on the Indian railways. During the last eighteen months of the War he (Sir George Buchanan) travelled 49,000 miles on Indian railways, and his experience was quite the contrary to that of Sir William Joynson-Hicks, as he found that when in the course of a journey a train lost an hour's time, it continued losing time, and arrived at the terminus often four to six hours late.

LIEUT.-COLONEL SIR CHARLES H. BEDFORD, LL.D., D.Sc., M.D., said he had just come back from Burma, and he constantly encountered complaints with regard to the backwardness of that Province in railways and in roads. The commercial community in Burma felt strongly the neglect from which they suffered by lack of development of communications, the feeling being that Burma was a specially rich milch cow for the Government of India, who withdrew from it an undue proportion of revenue for general purposes, and that Burma was relatively starved in the matter of money for the development of railways and roads. The only fairly good road in Burma was the military road running from Rangoon to Prome. The necessity for cross roads linking up certain of the waterways was great. He hoped that the Government, hand in hand with their industrial developmental schemes, would press forward the extremely important subject of communications.

MR. H. KELWAY BAMBER, M.V.O., exhibited an interesting series of lantern slides showing the various methods of rail and road locomotion in India. He suggested that had internal combustion engines and motor cars been in as an advanced a condition ten years ago as to-day, much of the money spent on light feeder lines would have been expended on roads and motor cars. He believed that in the future this form of transport would be extensively developed, and there were no doubt many places in India where feeder roads could be constructed with very great advantage, and with satisfactory commercial results.

Sir Charles H. Armstrong said he was recently in the canal colonies of the Punjab, and had been very much struck with the excellence of the roads there round about Montgomery and Okara. In developments of that kind first-class roads should be made, so that produce might easily be brought to the stations. Also while in India recently he motored from Delhi to the Kutb Minar in the very greatest comfort. Railways in India had been passing through a very difficult time, and the rolling stock was not as it should be, and engines could not work to their full power. At present they had to use an inferior class of coal. He thought, however, that as soon as the railways could obtain renewal supplies there would be a very great improvement in the railway service in India.

Mr. T. J. Bennett, M.P., C.I.E., in proposing a vote of thanks to the author of the paper, said Lord Montagu had done a great service in calling attention to the shortcomings of the Government of India in regard to its main roads. Early in last year Parliament had been engaged in considering the Transport Bill, and the fear of many was that the Transport Minister, being a railway man, might show more affection towards the railways than the roadways; but protection was afforded against that danger by the appointment at the Ministry of a Chief of the Road Department, who was as great a man in roads as Sir Eric Geddes was in railways. From the experience of India it was possible to see a disadvantage and a danger in this country if at any time there was an obsession on the part of a Railway Minister to dominate the policy of the Ministry of Transport. The author had given some very useful suggestions as to the lines upon which a road policy in India should be carried on. He believed the arrangements under the new system of government in India contemplated that military roads should be an Imperial subject, while roads that were not of a military character should remain in charge of the Provincial Governments under a Minister. He thought it would be an advantage for the Provincial roads to be in charge of the Provincial Governments, because local influence would be brought to bear upon the administration, and when taxation had to be resorted to for improvement of the roads it would have to be done with the consent of the people themselves, who would have to pay for the work.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., in seconding the motion, said one of his greatest regrets at the end of the Afghan War last April was that peace was not declared by our generals on Afghan soil at Dakka, instead of bringing the Afghan Delegation to India and wasting two months in negotiations there. It would have been far better to have said that Dakka was to remain British territory in the future, and that the railway [illegible] completed to Dakka from Jamrud. The [illegible] for road communications as well as railway communication in India was very [illegible] made last year [illegible] out the Punjab, [illegible] plainly how necessary it was [illegible] road communications [illegible] communications. He also [illegible] great necessity of planting trees [illegible] roads and of tarring the roads. Water communications were also a great necessity.

The resolution was carried unanimously.

Lord Montagu of Beaulieu, in reply, said he remembered telling the Viceroy that if he did not make good lateral roads the tribes would become more formidable in future. He had to thank the late Viceroy (Lord Hardinge), the present Viceroy (Lord Chelmsford), the late Secretary of State (Mr. Austen Chamberlain), and the present Secretary of State (Mr. Edwin Montagu), as well as Generals Barrow, Cox, and Cobb, under whom he had served, for the great help they had always given to him when he tried to tackle the question under discussion.

The meeting then terminated.

IMPORTANCE OF THE JAVA SUGAR INDUSTRY.

Java is the third largest sugar-producing country in the world, ranking next to Cuba and British India. As the last consumes practically all that it produces, Java ranks next to Cuba in sugar exports, actual production being about half of the Cuban output, and approximately three times the production of the Hawaiian Islands. Compared with the Hawaiian industry, where, it is understood, there are about fifty sugar centrals, Java has at present 186 producing mills.

It appears from a report by the United States Consul at Soerabaya that, on account of the density of population in Java, which is estimated now to be more than 30,000,000, the Government does not permit of large concessions of land, and will allow the use of any given tract of land for sugar production for only one year out of three, requiring that rice be planted for the other two years. This necessitates a rotation of crops in three-year periods, and continually reserves two-thirds of the available sugar land for the production of rice. This has been found to be a very wise provision, since, even under the present system, the consumption of rice is greater than the production in Java in normal years, so that the country is somewhat dependent on the near-by rice-producing countries for imports of the staple food supply. During last year there was, in fact, considerable discussion looking toward the further restriction by Government of sugar cultivation, in order that the local rice production might be increased. This proposal was eventually

abandoned, however, in view of the importance and value of the sugar crop at the present time of great world demand and consequent high prices.

The sugar-mills are for the most part large modern plants, although some of the labour-saving devices in common use in many other countries are not used owing to cheap and plentiful labour. There is now, however, a growing interest in labour-saving appliances and machinery, due to the increased cost of labour and a certain amount of labour trouble which seems to be prevalent to-day in Java as well as other parts of the world. Java sugar-growers are now, for the first time, coming to a realisation of their rather precarious situation in depending so completely on unskilled labour.

It would appear that the time for the introduction of labour-saving machinery is rapidly approaching, and careful and systematic efforts by manufacturers in this direction should bring results during the next few years. Most of the estates are supplied with light railways, operated with small, light wagons, but many still rely largely on bullock-carts for bringing the cane to the mills and native labour in handling it. Many estates use small wagons on the light railways, either pushed by hand or drawn by bullocks, while only a few have locomotive equipment.

The transportation of cane is especially difficult in Java, because of the fact, above mentioned, that planted areas are in small plats interspersed with plots of rice paddy, so that a plantation of 2,000 acres of cane is compelled to extend its transportation system over territory of three or four times that amount of land. Figuratively speaking, a plantation of four square miles of cane, where the longest haul would be about a mile if the mill were placed in the centre of a compact tract of that size, would require a long haul of more than two miles, if only a third or fourth of the land is in cane. Actually the difference is, in many cases, considerably greater than in the above hypothetical case, since the plats are not arranged with mathematical precision. A certain plantation, for example, of approximately 4,000 acres under cultivation, must haul the cane about eight miles from some of its more distant fields. As the plats are changed from year to year, much of the light railway must be portable.

A NOVEL SYSTEM OF AERIAL RAILWAY.

It is stated by *L'Eclaireur*, of Nice, that a novel system of aerial travel has been invented by M. Henri Coarda, a well-known French engineer. According to that journal, the plans for the construction of the first line to be constructed in the Department of the Alpes Maritimes have already been submitted to the Prefect for authorisation. The new system to be adopted consists, mainly, in establishing a fixed cable line between the two extremities. From this cable, to be supported at a suitable height above the ground by posts placed at intervals, will be hung specially constructed avions or aeroplanes, to serve as passenger cars. These, which will be quite independent of each other, will serve as the passenger cars. They will be provided with the usual screw propeller, and planes or wings, as in use for independent aeroplanes. They will be driven in the usual way by a motor at a speed of about 150 kilometres per hour (about 100 English miles).

M. Coarda proposes to construct a first and trial line from the sea-coast at Meulon to Piera Cava, a well-known summer resort, about 30 miles to the N.E. of Nice, and at 1,500 metres (4,800 feet) altitude. The total length of the proposed line from Meulon will be about 36 kilometres (22 miles), and it is estimated that the journey would occupy about twenty-five minutes.

If successful, other lines would be immediately constructed to other places in the mountains, which, owing to difficulty of transport, are little frequented by the public.

It is to be hoped that by means of such air-lines Nice and Paris will be brought within six or seven hours' journey from each other.

HONG KONG'S TRADE IN PRESERVED FRUITS.

The export of preserved fruits from Hong Kong, according to the American Consul there, generally known in the trade as "preserves," and including many Chinese delicacies such as cumquats and lichees and various combinations such as "chow chow," is showing a sharp revival with the renewal of trade to Europe; exports to the United States also have shown a marked advance. Shipments from Hong Kong classified as "preserves" to all countries in 1919 were valued at 405,183 dols., of which Great Britain is credited with 104,543 dols. and the United States with (declared value) 151,793 dols. as compared with a value of 101,778 dols. in 1917. Australia, Canada, and various parts of China took practically the whole of the balance. The American figures also include a fair amount of tinned Chinese fruits. During the first half of 1919 the United States was credited with declared exports of preserves to the value of 86,646 dols., as compared with a declared value of 36,341 dols. for the first six months of 1918. The Hong Kong statistics indicate total exports of this general class "preserves" for the first three months of 1919 amounting to a value of 275,129 dols., of which Great Britain took 195,955 dols.

As in the case of ginger and similar products from this field, the high price of sugar militates against any very great increase in the trade, not only because the sugar which is used in the manufacture of these preserves costs 11·75 dols. gold per picul (133⅓ pounds) as compared with 6·76 dols. gold a picul a year ago, but also because the actual supply of sugar on hand in Hong Kong has been limited. The result has been a hesitancy on the part of manufacturers to sell for future

deliveries until they have the necessary stock of sugar in hand. This trade in preserves is one of more importance in local trade in Hong Kong than its actual volume indicates; for the preserve factories employ a considerable number of people and their materials are grown in the vicinity of Hong Kong, so that growers depend upon this port almost entirely for their market.

OBITUARY.

FRANCIS EDWARD ROBOTHAM.—Mr. Francis Edward Robotham, who was elected a Fellow of the Royal Society of Arts last year, was drowned in a boating accident in Finland on June 24th, at the age of thirty-five. He was educated at Manor House School and the City of London School. Being ineligible for the Army on medical grounds, he assisted in preparing the Clapham portion of National Registration, and subsequently became Honorary Secretary for the Clapham South Ward Food Control Committee. He was a keen student of microscopy, especially as applied to bacteriological research, and was a Fellow of the Royal Microscopical and of the Linnean Societies.

GENERAL NOTES.

EXTINCT ANIMAL REMAINS IN SOUTH AUSTRALIA.—Some eight years ago portions of a giant Nototherium were found near Smithton, recalling the Diprotodon bones found twenty years ago in Lake Callabonna in South Australia. Now further remains in the Mowbray Swamp have been discovered. The find is a skeleton of Sir Richard Owen's "Nototherium Mitchelli," which it is contended is quite distinct from the "Nototherium Tasmanicum," referred to above. The present specimen is much mutilated upon the right side, evidently having died in shallow water, but the left side and the skull being more deeply buried have escaped the exposure that ruined the pelvis and the right limbs. From the more complete left side much valuable scientific evidence regarding the feet, hands, and other parts will be obtained. De Vis, the great Australian palæontologist, of Queensland, in 1888 claimed that the three generic races of Nototheria existed in pleistocene time. The remains they are getting out will probably clear up some points in regard to this question. It must be remembered that Professor Owen never saw all the bones of the animal he called Nototherium Mitchelli. It is of much interest to see that the arm bones which Huxley and his followers thought to belong to a small race of Diprotodons really did belong to Nototherium, as Owen always contended. The work of the excavator is very difficult. The diggers, dressed in gum boots and waterproofs, are always up to their waists in the awful mud of the old swamp that bottoms here at well over 6 ft. It is well known that Australia is one of the oldest lands on the earth, and these giant relics of bygone ages are of intense interest.

THE PEAT INDUSTRY OF DENMARK.—The Danish production of peat for the years 1916, 1917 and 1918 was respectively 280,000 tons, 1,800,000 tons and 2,250,000 tons. In 1918 the working capital invested in this industry was 58,000,000 crowns. At the average price of 40 crowns per ton, the total value of the peat produced in 1918 was 90,000,000 crowns. When it is considered that 2½ tons of peat are equal in heat value to 1 ton of coal, the peat produced in 1918 substituted imported coal to the value of 126,000,000 crowns. The future prospects of the peat industry are not considered to be very good, the principal difficulty being the poor facilities for transporting the peat from the bogs to the consuming centres. Peat played a very important part in taking the place of imported coal during the war, and it is now being used to a large extent on account of the coal shortage.

SILK RESEARCH ASSOCIATION.—The Research Association for the Silk Industry has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. As the Association is to be registered as a non-profit-sharing company, the promoters have applied to the Board of Trade for the issue of a license under Section 20 of the Companies (Consolidation) Act of 1908. The Secretary of the Committee engaged in the establishment of this association is A. B. Ball, Esq., The Silk Association of Great Britain and Ireland, Kingsway House, Kingsway, W.C.

GERMAN PROCESS FOR MANUFACTURING ARTIFICIAL WOOL.—According to a Belgian authority, there is considerable interest in Germany in a patent recently taken out for a process for the manufacture of artificial wool. In principle, the process consists of compressing wool scraps which cannot be otherwise utilised—shreds, ends, short fibres, washing wastes, etc.—and soaking them in a viscous solution of cellulose or one of its compounds with a small percentage of glue; the product thus obtained is cut into thin sheets and strips, which can be treated after the manner of paper yarn. The Germans claim that the yarn thus obtained possesses all the properties of real wool. It is made waterproof by treating it in the process of manufacture with compounds of chromium, and later with formaldehyde and tannin, after which the product will resist the action of boiling water. The addition of glycerine gives it sufficient flexibility. This process is now being modified, writes the United States Trade Commissioner at Brussels, by the mixture with the woollen waste of a certain percentage of paper pulp and treating the product with sulphuric acid and zinc chloride. The addition of various other compounds gives it the necessary flexibility and makes it waterproof.

Journal of the Royal Society of Arts.

No. 3,530. VOL. LXVIII.

FRIDAY, JULY 16, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday, July 12th, at their first meeting in the new session, the Council elected Mr. Alan A. Campbell Swinton, F.R.S., Chairman for the ensuing year.

COUNCIL.

On Monday, July 12th, the Council elected Lord Sanderson, G.C.B., K.C.M.G., a member of the Council and Vice-President of the Society in place of Viscount Cowdray, who was unable to serve; and Sir Philip Magnus, Bt., M.P., a member of the Council in place of Viscount Elveden, C.B., C.M.G., M.P., who was prevented by his engagements from accepting office.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Monday, May 31st, 1920; Sir Robert W. Carlyle, K.C.S.I., C.I.E., in the chair.

The Chairman, in opening the meeting, said that the author of the paper, Mr. Albert Howard, had been the Imperial Economic Botanist to the Government of India since 1905. All that time his wife had been associated with him in his work, and she was now formally acknowledged by the Government as his colleague. Mr. Howard would deal with some of the most important lines on which agriculture in India was being run and improved. As a Member of Council of the Government of India, he (the Chairman) had been in close touch with Mr. Howard's work, and had learned to put the greatest value on his judgment, and he felt it a privilege and pleasure to have been able to remove difficulties from his path.

The paper read was—

THE IMPROVEMENT OF CROP PRODUCTION IN INDIA.

By Albert Howard, C.I.E., M.A., F.L.S.,
Imperial Economic Botanist to the Government of India.

I.—Introduction.

Agriculture is, and for many years to come must remain, India's greatest industry. In comparison with the value of the annual produce of the soil and the trade in raw materials, the remaining industries of the country are, with few exceptions, relatively unimportant.

When we examine the agricultural products themselves, it is at once evident that crops are of far greater importance than animals. The Indian cultivator is a grower of crops, and he usually regards his live stock as mere aids to cultivation and in the feeding of his family. The country does not export meat, wool or dairy products. When, therefore, the present Indian Agricultural Department, founded by Lord Curzon in 1904, began operations, the attention of its members was mainly directed to the study of the crops of the country.*

As is well known, the agricultural conditions of India and its problems are entirely different from anything to be found in the West. The investigators speedily realized that they were in a new world. The crops were seen to be raised by a multitude of small cultivators—conservative, for the most part poor and unable to command much credit. The average yield per acre was low but remarkably constant.

While the average production showed no change, the seasonal variations in yield were considerable. India was found to be a country of climatic extremes not only as regards the rainfall, but also with reference to temperature, to floods and high winds. Except in certain

* Recently, much attention is being paid to the milk supply in the towns of India, and to the improvement and feeding of the indigenous breeds of cattle.

favoured localities, the annual crop was always at the mercy of a variety of circumstances quite beyond the control of the cultivator. It was not surprising, therefore, to find him conservative in his outlook, and to discover that his leading idea in crop production was to play for safety.

The easiest line of advance in improving production lay through the plant. The problem was successfully attacked in two directions, namely, by the provision of improved varieties and by the study of the factors which influence plant growth. It will be convenient to deal with these two lines of work separately.

II.—The Improvement of Varieties.

The Indian cultivator rarely pays much attention to the seed he sows. Seed merchants in the English sense do not exist. With a few exceptions there is no attempt to keep the various varieties separate, so that mixed crops are the rule. Most of the kinds grown are low yielders of no particular quality, and with little power to respond successfully to improved soil conditions. This want of attention to the variety and the absence of high quality in the final product, all correspond closely with the general low standard of agriculture.

The field of work for the plant breeder in India was an ideal one. Nothing had been done. The country was vast, and was made up of large tracts such as the alluvium of the Indo-Gangetic Plain, the black soils of the Peninsula and the deltas of large rivers, where the general agricultural and soil conditions over large areas were far more uniform than in a country like Great Britain. The work of improving the varieties was started in 1905, and during the last fifteen years a large volume of results has been obtained. It is impossible in the limits of a single paper to do anything like justice to this work, which comprises scientific investigations on the inheritance of characters as well as others of immediate practical importance. New varieties of wheat which add every year more than £1 an acre to the profits of the cultivators now cover almost a million acres. Similar results are being obtained in the case of rice, jute, and tobacco. The crop to which most attention has been paid is cotton, and in the principal areas in which it is grown the distribution of new varieties has already affected large areas. Instead of describing this progress in detail, I propose to confine my remarks to a number of points of general interest which have arisen in the course of the work. These refer mainly to the variety and to the distribution of seed.

Some Varietal Characters.

Uniformity of Product.—Modern industry demands a uniform product. Not only must each consignment be up to sample, but the product should not change materially from year to year. In this way a reputation is established and the work of the merchant and of the manufacturer is facilitated. The mixture of varieties which goes on in the fields of the cultivators and the want of attention to the seed supply, run counter to this demand. It results in serious loss of uniformity in the produce. Further admixture often takes place after the seed has left the threshing floor. The result is that Indian produce lacks that uniformity and evenness which modern industries demand. This state of affairs renders it easy to bring about the first stage of improvement in crop production, namely, the cultivation of an even product free from admixture. Several successful schemes of seed distribution have been based on this principle. The mixed varieties in a tract are separated, grown side by side, and the most promising strain is then adopted for general distribution. As the mixed crops always contain many poor types, the yield of the pure strain is often a little greater than that of the country crops. Provided the seed distribution is effectively carried out, the local markets at once benefit by supplying to the trade a definite grade in place of a somewhat inferior mixture. A good example of such an improvement is the distribution of the wheat known as Punjab 11 in the Canal Colonies. This is the predominant constituent of one of the local mixed wheats which used to be very popular among the cultivators round Lyallpur. The mixture is now being replaced by one of its constituents to the advantage of all concerned.

Yield.—The importance of yield in any new variety cannot be over-estimated in India. The cultivator is conservative and is not prone to change either his methods of agriculture or the local varieties of crops to which he is accustomed. It is difficult to make him take an interest in questions like improved quality unless an enhanced price can be obtained at once. Every cultivator, however, can understand the meaning of a good crop and of a variety which can be relied upon to produce a yield above the average. Once this is assured, the success of any new variety is certain, and no difficulties in obtaining his co-operation need be feared. While yield is of such paramount importance in India, it must never be forgotten that the growing period of the crop is much more strictly limited than in countries like Great Britain.

Generally speaking, in England there is a fair degree of latitude at both ends of the season. In India this is not the case. For example, the sudden change from the monsoon to cold weather conditions in Northern India, and from the cold season to the hot months, impose temperature limits which restrict growth to a definite period. Thus in Bihar, the period during which wheat must be sown to ensure a full crop, is less than ten days. Early sowing is impossible, as the soil is too hot for the seedlings; late sowing means a great slowing down in growth due to the rapid fall in temperature, and the crop cannot ripen in time. More important than the time of sowing are the factors which affect the crop during the ripening period. A rapid rise in temperature takes place in March, the hot weather is ushered in with dry hot winds, and the transition from a period when wheat can ripen to one in which it merely dries up is a matter of a few days only. Once the hot winds begin, ripening ceases, the crops wither and shrivelled grain is the result. Early hot winds or a spell of hot weather may reduce the yield by half. Experience proves that a variety which ripens well within the growth period of any particular locality gives the best return over a number of years. It sometimes happens that in exceptional seasons a late, high-yielding wheat may give a crop considerably higher than that yielded by the more rapidly maturing kinds. The position is, however, reversed in average years, while in very short seasons the rapidly maturing kind gives a fair crop, and the high yielding type practically nothing beyond straw. Yield is often a pitfall for the plant breeder in India, where it is always safe to disregard the results of exceptional seasons. Many examples could be given where serious mistakes of this character have been made. Some years ago, one of the Bihar indigo planters was very much impressed by the appearance in the field of one of the late durum selections—No. 20. In spite of being warned, he obtained sufficient seed for sowing several hundred acres of his estate. The growth was magnificent, and the promise of a bumper crop seemed certain. Ripening, however, was interfered with by hot winds, and the crop was not much more than half the estimated yield. A similar experience has often been obtained with Muzaffarnagar wheat, a country mixture which does well under irrigation in the Meerut Division of the United Provinces. In certain years it also does well in Oudh and Bihar, but on the average it only produces low yields of rather shrivelled grain due to hot weather during the ripening period. It is a remarkable fact that in many parts of India some or all of the country varieties of wheat grown are on the late side. The samples at harvest time often contain a high proportion of rather thin grain, particularly in tracts like Oudh and Bundelkhand. A great improvement in yield has been obtained by introducing a wheat of shorter growth period which can use up the limited time to the best advantage, and which can produce a well-developed grain even in unfavourable years.

In this connection, another interesting aspect of yield has arisen in India, where the standard of agriculture and the general resources of the experiment stations are far in advance of those of the people. Particularly is this the case with irrigation facilities. When yielding power is studied under these favourable conditions, varieties come to the front which prove very disappointing when tried by the cultivators. One of the highest croppers of the local Punjab wheats—No. 9—is a variety which gives good yields if well cultivated and provided with sufficient water at an experiment station. Under cultivators' conditions, however, it is apt to prove disappointing, and to yield less than earlier types of lower potential yielding power. Similar experiences have been met with at Pusa. It therefore follows in India that the variety which possesses the highest potential yielding power is not necessarily the best for introduction to the cultivator. A great deal of judgment is required in selecting the most likely kinds for such a purpose. It is a safe rule to discard all types which show the least tendency to mature late or to require special treatment. For these reasons, accurate mathematical investigations to determine which of a set of varieties is the highest yielder, which may prove of great use in a country like England, are often inapplicable to Indian conditions where the results are only of academic interest.

Adaptability is essential to the successful variety. That is to say, it must do well over a wide range of conditions, and it must also respond successfully to improved cultivation. It is an obvious advantage to all concerned to distribute as few improved kinds as possible, and the number can be materially reduced if only those possessing great adaptability are finally adopted. The best indigenous varieties in India are often defective in these respects. They only do well in a very restricted area, and when the cultivation is improved they break down at once. Thus in Rohilkhand, local varieties of

sugar-cane are well suited to the primitive conditions under which they are grown, but the moment they are intensively cultivated they run to excessive vegetative growth rather than to sugar production. The same applies to the country wheats which are useless for more intensive cultivation and only produce, under these conditions, a mass of weak vegetation which is at once laid by even moderate storms. Really improved types of sugar-cane and of wheat, while doing well under ordinary treatment, will also respond successfully to better soil conditions. This question of the adaptability of a variety is really important in India, and should be applied rigorously to all new kinds. It used to be the fashion to say that an enormous number of new varieties would have to be evolved to suit the various tracts, but this idea has not been borne out by experience. Thus the variety of cigarette tobacco known as Type 28, originally evolved to suit the conditions in the Tirhoot Division of Bihar, has been found to do well in South Bihar, in Orissa, in the Central Provinces and Central India, in the United Provinces and also in Burma. Pusa 12 wheat is now doing well in South Bihar, in Oudh, in Rohilkhand, in the Province of Agra, in the Eastern Punjab, on the Canal Colonies, in Sind, the Central Provinces and also in the hill tracts of the North West. Pusa 4 is rapidly spreading in North Bihar, in the North-West Frontier Province, in Bundelkhand, in Assam, under irrigation on the black soils of the Peninsula and in many other localities where a rapidly growing variety is needed.

Like many other successful things, the improved variety is a compromise and does not depend on excellence in a single character. Such things as yielding power and adaptability represent a combination of characters which it is practically impossible to analyse on the score card principle. No one has yet given a satisfactory quantitative expression to the various units which make up yielding power. A plant breeder, working on score card principles, might easily reject a really good variety. Being a compromise, it follows that too much attention must not be paid to single characters. Rust resistance in wheat is a good case in point. Before the present Agricultural Department was started, a great deal was heard about the desirability of obtaining rust resistant wheats for India. It was thought that once these could be secured, all would be well with the wheat crop. In reality, however, this is not the case. Many rust resistant wheats have passed through my hands at Pusa which were quite useless for any purpose beyond plant breeding. The quality of rust resistance was united with so many weaknesses in other respects that the wheats were little more than curiosities. Naturally the ideal wheat will be highly rust resistant, but in practice it is better to unite with vigour, adaptability, good yielding power, good quality, and good straw, a fair degree of rust resistance, than to pay too much attention to this one point.

While single characters by themselves are generally useless, nevertheless a trivial colour character, when in combination with others, may be of great use when the seed of an improved kind has to be distributed among the cultivators. In the systematic replacement of the country crop, the Agricultural Department must be able to check the work. The replacement must be carried out according to plan, and admixture with inferior types must be easily detected. For this purpose, the improved kind must be readily recognised in the field. It is a great advantage, therefore, if it possesses some distinctive colour characteristic by which it stands out clearly from the ordinary crop. In cotton, any peculiarity in the colour or shape of the flower is important, while in wheat, chaff and straw colour are most helpful.

Quality.—While yield is usually more important than quality, nevertheless questions of quality are often worthy of attention. As is well known, yield and quality are rarely combined in one variety. High yielders often possess low quality, while varieties of the highest quality are seldom satisfactory on the question of yield. While it may not be possible to combine the highest yielding power and the highest quality in one variety, nevertheless high yield can be united with quality far above the average. This has already been done in India in a number of varieties of cotton, wheat and tobacco.

Of perhaps greater difficulty than the union of quality with yield is the satisfactory sale of good quality. Payment for yield is easy and immediate. Payment for quality is often a slow process. Take the case of cotton. Here it is much easier to produce an improved variety than to establish it successfully and to ensure a proper price to the grower for quality. First of all, the seed supply has to be organized, which is by no means a simple matter. The greatest attention has to be paid to the prevention of cross-fertilization in the field, otherwise an improved cotton will rapidly degenerate. The cultivator must also be prevented from filling

up the blanks after sowing with inferior varieties, as recently happened on a large scale in the Punjab. The greatest difficulty is the ginning, as during this process the cotton-seed passes for a time beyond the control of the grower and of the Agricultural Department. The next step is to arrange for a large compact area of the improved kind, preferably near an important market, and to help the cultivator to obtain a fair price for quality. The traders say small lots are useless to them, and that a full premium cannot be expected unless thousands of bales are available. The Agricultural Department says the best way of obtaining thousands of bales is to encourage the grower by an immediate and substantial premium. This difficulty is being partly overcome by selling the produce to the local Indian mills, but this limits competition and is not a complete solution of the difficulty of the effective sale of quality.

In the case of crops like wheat, which are largely consumed in the country, and which rarely cross-fertilize, the sale of quality is simpler than in the case of cotton. There is much more competition. The moment the new high quality Pusa wheats, now being distributed in India, appeared on the local markets, they commanded a substantial premium, which has since increased. There was keen competition to secure the wheat for food. Export buyers, who wish to secure these wheats for shipment, will find the premium already fixed. Local competition in this instance has secured payment to the cultivator for quality. Special auctions, under the *ægis* of the Agricultural Department, have been unnecessary.

The Distribution of Seed.

The absence of the seed merchant in India throws much of the work of raising and distributing improved seed on the Agricultural Department. This work is now very important, and has already grown to enormous dimensions. Much time and thought have been devoted to the problems which have arisen from time to time, the solution of which is certain to interest many workers outside India.

The Methods of Supply of Pure Seed.—It is obviously impossible, in a country the size of India, for any Government Department to grow more than a very small portion of the total amount of seed required for sowing. In replacing the existing crops by better varieties, it has been necessary to build up large organizations for seed distribution in which the people co-operate with the Department. These organizations vary according to the Province and according to the ideas of the men who have set them in motion. They are necessarily more elaborate in the case of high quality cotton (where both admixture of seed and natural cross-fertilization have to be guarded against) than they are in crops like short staple cotton and wheat. All the schemes are based on the Government seed farms, at which the first supplies of pure seed are raised.

Till recently, the difficulty has been to supply sufficient pure seed for starting and re-stocking the local centres of distribution. Large, well-managed seed farms, from 200 to 300 acres in area, are now to be seen in several places, mainly as the result of a large grant in aid by the Government of India. The Supreme Government decided, in the early years of the war, to devote the profits arising from the control of the export trade in wheat to some public purpose which would help the tracts which produced the seed. The money was given to the provincial Agricultural Departments concerned, and devoted by them largely to the provision of new seed farms. The result has been a great impetus to the important work of seed distribution. Moreover, these large seed farms serve to demonstrate, in a very effective manner, the value of an improved variety. A stretch of a hundred to a hundred and fifty acres of an obviously superior variety, true to type and well grown, never fails to impress both the administrator and the general public, and to convince them of the reality of the work in progress. The seed farms conducted directly by Government serve merely as the sources of supply of pure seed for the various local centres, where the seed is further multiplied before distribution to the actual cultivator. These local centres of seed supply are mostly managed privately or by bodies such as Co-operative Credit Societies, District Boards, or the Managers of the Court of Wards' Estates. Every possible kind of local agency has been enlisted in this work. In this way, the Agricultural Department has been able to extend its influence considerably without having to expand its organization unduly. The local notables, such as the Taluqdars of Oudh, are beginning to be interested in the movement, and several members of this body now possess large, well-managed seed farms which are proving of great value in the development of Oudh.

Systematic Replacement.—Given a large quantity of the pure seed of an improved variety, and an organization for spreading it among the people, the most effective method of using it

is an important matter. Should it be concentrated in a few areas or should operations be started from a large number of centres? Both methods have been tried, but the tendency is now towards concentration in definite areas, and towards the systematic replacement of the crop by the improved kind.

The work is being taken up village by village, and large continuous blocks of one variety can now be seen in various parts of India. This system of systematic replacement has many advantages. Supervision is relatively easy, the effect of the improved kinds on the market is soon evident, and it is less difficult for the grower to obtain an enhanced price for uniformity and quality when large quantities of the product are available. The seed supply is greatly facilitated, while in crops like cotton the harmful effects of cross-fertilization in the field and of mixing of seed at the ginneries are reduced. All these advantages assist the Agricultural Department considerably. The obvious benefit to the locality of a successful replacement soon becomes known, and helps materially when work is taken up in new centres.

Finance.—One difficulty in seed distribution, which is also beginning to affect other branches of the work of the Agricultural Department, has not yet been satisfactorily solved, and that is the best method of finance. As is well known, the ordinary activities of Government are based on the annual budget, which is sanctioned early in the year and which from the nature of things is inelastic both as regards time and as regards money. The financial year ends on March 31st, when the budget lapses and a new one begins. Such a method of finance is obviously unsuited to large schemes of seed distribution often involving credit. The difficulty has partly been met by annual Treasury advances. These, however, have to be repaid at the end of the financial year and their use involves an enormous amount of trouble and correspondence. What seems to be required is a Development Fund quite outside the Government Account rules, but subject to audit, which will permit seed distribution to be financed on ordinary business lines. Such work as this is outside the scope of ordinary Governmental activities, and requires its own system of finance and of accounts.

III.—The Factors Influencing Plant Growth.

The improvement of crop production in India involves two distinct branches of work. Better varieties are needed, and improvements in the methods of growing them have to be devised. I have already dealt with improved varieties, and will now pass on to the second point. In working out improved methods of producing a crop, the physiological aspect is the one which concerns the economic botanist. The chief physiological factors influencing growth are water, dissolved materials (often spoken of as plant food), temperature and air. If any of these factors are in defect, growth is at once affected, and the yield falls. This applies to all varieties. At the moment in India, crop production is being seriously retarded by factors which interfere with growth over large areas. Once these are removed, the yield is increased.

Already the study of the physiological aspect of crop production has led to important practical results, but much yet remains to be done in this promising field. Perhaps no country in the world offers better scope than India for such work. We have before us an old civilization, with a corresponding volume of traditional experience in the growth of crops. This has helped to crystallize and define the agriculture of the country to a much greater degree than has been possible in our modern tropical possessions, or in new countries like the United States of America. In India, things agricultural have had time to settle themselves. The great growth factors have left their impression on the characters and distribution of cultivated plants. Besides this, the range in conditions between the various parts of the country is very considerable. These circumstances greatly assist the investigator in the study of the physiology of crop production and in the deduction of some of the factors which are in operation. To anyone who can read his practice in the plant and has acquired an intimate knowledge of crops, India presents in its agriculture a number of natural experiments repeated year after year. Besides, the country is now covered with a network of experiment stations, at which any preliminary deductions can be tested in the field. A study of the wider aspects of particular crops, when grown under very different conditions, combined with direct experiments, has led to results of great importance. I propose to deal with some of those which relate to two growth factors—soil-aeration and soil temperature.

Soil-Aeration.

Defective soil-aeration is an important factor in many parts of India. In the irrigated tracts it is a constant cause of low yields. It is

responsible for the poor growth of cotton and millets on the black soils of the Peninsula in wet years when the expansion of the subsoil hinders percolation. It is also operating in the forest areas, and in regions like Bihar in the rainy season, when the rise of the rivers and of the subsoil water prevents the aeration of the roots for long periods.

The importance of soil ventilation in agriculture has not always been sufficiently emphasized in the past. While the need of free oxygen in the respiratory processes of the active cells of the roots of plants and of many of the soil organisms has long been realized, little attention has been devoted to this in agricultural research. A little consideration will show how this has arisen. Till recent years, the Agricultural Experiment Stations of the Empire have been situated in humid regions, where the rainfall is well distributed. Rain is practically a saturated solution of oxygen and is very effective in supplying this gas to the soil whenever percolation is possible. Hence in such regions, crops are not likely to suffer from poor soil-aeration to anything like the same extent as those grown in the arid regions of North-West India, where the soils are silt-like and lose their porosity when the surface is flooded with the formation of an impermeable surface crust.

I propose to deal with three cases in which progress has been obtained through the recognition of the importance of the soil-aeration factor. The first of these concerns canal irrigation as practised in North-West India.*

Irrigation. — Recent investigations have shown that soil ventilation plays a very important part in wheat growing under irrigation in India. As is well known, the soil is not solid, but consists of particles more or less loosely packed with spaces between them. These spaces are known collectively as the pore space, and are taken up by air and water. It is essential for rapid growth that this pore space should be large and that its oxygen supply should be continually renewed. If this is not arranged for, the roots of the crop and the soil organisms suffer from want of air and growth is affected. Water is also required. The best method of supplying oxygen and water is by means of rain. The rain dissolves oxygen from the atmosphere and supplies both water and oxygen to the soil at the same time in the most effective manner possible. When, however, we push our cultivation into the desert and attempt to make up for the want of rainfall by surface irrigation, a difficulty at once arises. Flood irrigation, by producing a more or less impermeable surface crust and by reducing the volume of the pore space, seriously interferes with aeration. Irrigation supplies the water but it tends to deprive the soil of air. Obviously the solution of this difficulty is to arrive at a working compromise between the needs of the soil for water and for air, and to devise a method of applying irrigation water which interferes as little as possible with the aeration of the soil. A large number of experiments on this point were carried out, of which a short account will now be given. The first experiments were designed to find out what kind of crop could be grown without any watering at all after sowing. These were carried out at Quetta, and the land was watered once only before sowing. The results are given in Table 1:—

TABLE 1.

YIELD OF WHEAT AT QUETTA WITH A SINGLE IRRIGATION.

Season	Area in Acres	Yield of Grain per Acre	
		m.	s.
1912–13	3·00	18	30
1914–15	2·85	16	28
	Average	17	29

One Maund = 40 Seers = 82·27 lb.

The next step was to compare the crop grown on one watering after sowing with that obtained when three waterings were given. The figures are given in Table 2 (see p. 562).

These results showed that after the first irrigation no further advantage was obtained by giving more water. On the other hand, harm was done by interfering with the air supply by the formation of a thick surface crust, and the

* It was observed some years ago that in areas like the Canal Colonies of the Punjab and in the Quetta Valley, where wheat is irrigated several times, the crop ripens much more slowly, that there is far less development of chaff and straw colour with thinner grain than when the plant is grown on natural moisture, and where the porosity of the soil is good. These differences were found to be due to the different conditions of soil ventilation in the two cases.

TABLE 2.

THE INTRODUCTION OF A NEW LIMITING FACTOR AFTER IRRIGATION.

Number of Waterings	Area in Acres	Total Weight of Produce	Total Weight of Grain		Yield of Grain per Acre		Percentage Reduction
		lb.	m.	s.	m.	s.	
One . . .	3·99	10,367	52	6	13	2	0
Three . . .	2·65	6,620	25	15	9	23	26

destruction of the porosity of the soil. Similar results were obtained in the Punjab (Table 3), in Sind (Table 4), and in the United Provinces (Table 5 and Plate I.).

A consideration of all these results indicates that over the canal irrigated areas of North-West India, a vast volume of water is annually poured on to the land to no purpose. At a

Total . . .	10·8	357	Average 33·1

comparatively early stage in irrigation, the aeration of the soil is interrupted, after which any further addition of water does not affect the yield. Not only is the water wasted, but the natural fertility of the soil is lowered, as is seen by the gradual falling off in yield on new canal areas, and by the increase in the area of alkali lands. The remedy appears to lie in a change in irrigation policy and the gradual introduction of a system of charging for the water by volume rather than by the area irrigated. This will lead to much less water being used. Such a radical change would require time. The consent of the cultivator on existing canals would also have to be obtained before the present system could be altered. There seems, however, no reason why payment by volume could not be applied to all new canals. It would lead to a great saving of water, to an enormous increase in revenue, and it would help to preserve the natural fertility of the soil.

Development of Waste Lands.—The second practical application of soil-aeration concerns the utilisation of some of the uncultivated areas of the country. The publication of the earlier results on the influence of soil-aeration on growth naturally attracted attention to the value of soil porosity and to soils which possessed good drainage. If soil-aeration is such an important growth factor, it would follow that soils possessing great porosity would often prove to be of the greatest value. Clouston, working in the Central Provinces, was the first to make any practical use of these ideas in India. In this Province, large areas of poor laterite soils occur which were considered below the margin of cultivation. They produced, for the most part, a thin growth of grass in the rains with an occasional millet crop. Although exceedingly poor in the ordinary sense, these soils possess excellent porosity and a texture which is unaffected by irrigation. By the addition of organic matter and by providing irrigation facilities, these useless areas have been transformed into garden land of the highest quality. Crops of over forty tons of stripped cane to the acre have been grown, as well as heavy yields of cotton, ground nuts, indigo seed and fodder (Plate II.). In all cases, the crops grown on these poor *bhata* soils were far heavier than those produced by the richer black soils in the neighbourhood, which were, however, much heavier and far less permeable. Not only was the yield greater, but there was a marked improvement in quality, and what is more striking, an entire absence of disease. These open permeable soils, by promoting aeration and nitrification, stimulated healthy

root development, which in turn led to increased yields. The facts that the quality improved and that the crops grown were free from disease, indicate new lines of work on the factors on which quality depends, and on the connection between soil-aeration and disease resistance.

(*To be continued.*)

CHROME ORE DEPOSITS IN ASIA MINOR.

It has been said that Asia Minor is very rich in poor mines. The country is indeed rich in the number of its mineral deposits, but it must be remembered that the field has never been thoroughly and scientifically surveyed so as to justify a verdict in regard to whether these deposits are rich or poor.

Chrome ore deposits are to be found in Asia Minor among the eruptive rocks of serpentine formation. The four most important districts where chrome mining has been more or less developed are the Provinces of Smyrna, Brúsa, Adana, and Konia. The working of chrome mines in the Province of Smyrna was started some twenty years ago.

Among the forty chrome mines for which firmans (concessions) have been granted, only eighteen have been worked. Twenty other research permits have been issued. Most of these mines are worked in a primitive way and modern methods not having been introduced, it would be difficult to ascertain the real chrome resources of the country. Specimens of chrome ore taken from deposits in the different districts in Asia Minor proved to be rich in chromic oxide ($Cr_2 O_3$), the percentage varying between forty and fifty-five. The maximum annual production of chrome mines in Turkey amounted to 30,000 tons before the war.

Besides the lack of modern mining processes, the very inferior state of roads and communications has been another drawback to the progress of these enterprises. There are a great many mines which have not been worked, on account of their being distant from a sea-port or a railway line, and about which little, if any, information is available. According to an Italian mining engineer of thirty years' experience in Turkey, the geological structure of the Erzerum and Erzindjan regions being partly of serpentine formation, chrome deposits might well be discovered in these provinces; investigations have not been made so far, because of the comparative inaccessibility of these regions from seaports or railways. The insecurity in the interior and the reluctance of mine-owners to invest money have constituted additional impediments to the progress of mining enterprises. Moreover, the laws of the country concerning mines do not promise proper advantages

or security to holders of concessions. Consequently, foreign capital has not been forthcoming.

According to a report by the United States Consul-General at Constantinople, the chrome-producing districts of Turkish Asia Minor may be classed in four zones, according to location, as follows:—

Brusa zone.—Chrome ore is found in this zone in the Sanjak of Kutakia, near Tavshanli, mining district "Dagh-Arde"; in the Sanjak of Brusa, near Harmandjik, at 31 miles from Adranos, and also at 15½ miles from Adranos; and in the Angora Province, near Mihalidj, 3 miles from Eski-Chehir-Angora railway.

Smyrna zone.—There are chrome ore deposits in the Sanjak of Menteche, at a distance of 6½ miles from Makri; also in localities situated 23 miles south-east of Moughla, and 16 miles from the Aidini-Diner railway, near Denizli, respectively.

Adana zone.—Ore is found in the Sanjak of Adana at a distance of 23 miles from the town of Adana; in the Sanjak of Mersina near Elvanli; and in the Sanjak of Djebel-Bereket, Kaza of Yarpouz, at a distance of 16 miles north-east and 9 miles south-east of Yarpouz, near the Bagdad Railway.

Konia zone.—There are two mines in the Sanjak of Reke, Adalia, one at a distance of 6 miles, and another at a distance of 25 miles from the sea. The Sanjak of Konia has one mine; and ore is found also in the Sanjak of Hamidabad, at a distance of 16 miles north of Sparta, and on a highway leading to Dinar, which is a terminal station of the Aidini-Dinar railway.

Chrome Mines in the Province of Brusa.

The physical character of Brusa Province, its climate, the structure of the rock, its water supplies, and forests, are favourable for mining operations, or at least present no special difficulties. The annual output of the mines varies from 10,000 to 15,000 tons, and the ore is of a high grade. Research work in this Province has shown that there are more than 200,000 tons of ore available.

Mine of Dagh-Ardi.—This mine is situated in the district of Simay, near the village of Dagh-Ardi, at a distance of 37 miles from the Kutahia railway station, and 56 miles from Guemleik (near Ismid Harbour). It consists of two chrome ore deposits parallel to each other and inclined to the horizontal at an angle of 20°. They are a mass of formation of a thickness of 33 to 50 feet and of a grade varying between 44 and 52 per cent. After the process of reducing the serpentine to the maximum allowable percentage of 3 per cent., the grade of the ore could reach 55 per cent.; a mechanical treatment of the ore would raise its grade to 58 per cent. The extraction of chrome ore from the mine is attended with some difficulties; deep inclined and vertical shafts must be used in order to attack the mass of rock at low strata.

Scarcity of labour is at present a serious drawback to the remunerative working of this ore; wages also are very high. Mine operators suggest the transfer to mining districts of groups of workmen from China and Japan. During the war the Dagh-Ardi mine was managed by a German firm and the ore was sent to Germany. This firm established transport facilities by an aerial railway 14 miles long.

Besides the two deposits mentioned there is a third one called Kervan. The grade of this ore is 33 per cent. It can be used after a thorough and proportional mixing with high-grade ores and a mechanical treatment in the washing plant.

Mine of Dombay Olduyi-Deressi.—This mine is at a distance of 2½ miles from the Dagh-Ardi mine. It is of mass formation, its grade being from 45 to 48 per cent. Transport of the ore is facilitated by the aerial railway, which crosses this mine. These deposits have not yet been worked, only research work having been carried out.

Terzi-Pounar Mine.—Situated at a distance of 6 miles from the Dagh-Ardi, and located on a wagon road. Its grade is from 50 to 52 per cent. Prospecting has been undertaken, but no real work has been inaugurated.

Assarlik Mine.—Situated at a distance of 4 miles from the Dagh-Ardi, and quite near the wagon road. Its grade is 48 per cent. Only prospecting has been done so far.

The three mines mentioned above have to be worked in conjunction with the Dagh-Ardi mines.

Karadja Keny Mine.—Situated near Karadja-Keny, at a distance of 22 miles from Kutahia; it is of vein formation and perpendicular bearing. The grade of the ore is 48 to 50 per cent. The mine has not been seriously worked. It belongs to Turks. The ore is transported to Kutahia.

Karli-Yer Mine.—This mine is situated at a distance of 59 miles from the Kutahia station. The chaussée road extends from this station to Tavshanli, which is 19 miles distant from the mine. The grade of the output has always been on an average of 55 per cent. The total production for approximately 30 years has been 130,000 tons. This mine can produce 4,000 to 5,000 tons of 55 per cent. graded chrome annually. Its approximate future production is estimated at 100,000 tons. There are forests and water supplies in the neighbourhood of this mine, and the climate is healthful. The mine now belongs to Krupp.

Abandoned Mines.—Near Harmandjik, at a distance of 7 miles from the Dagh-Ardi mine, there exist three chrome mines. They were worked by Krupps during the war and have an

uncertain status at present. The Kozloudja mine, one of the three, is situated at a distance of 3 miles from the Dagh-Ardi mine. It is of vein formation of 48 to 52 per cent. grade; the inclination of the seams is 45 degrees. The mine is exploited by underground works. A branch line of the aerial railway of the Dagh-Ardi mine will facilitate the transport of the ore. The Ardiranlar mine, situated at a distance of 7 miles from Dagh-Ardi, has yielded no great quantities up to the present. However, the production may be accelerated after serious research work. The mine is a mass of formation, graded 48 to 52 per cent. The ore is transported to Ghemleik, the nearest harbour. The ores of the Miranlar mine, situated 10 miles from Dagh-Ardi, are also transported to Ghemleik. This mine is in mass formation.

Other Chromic Deposits.—Between the Karadja-Keny mines and the Kutahia station four or five small chrome deposits of vein formation exist, graded 48 to 50 per cent. Prospecting should be undertaken and the quantity obtainable ascertained before beginning any enterprise.

Rich Deposits in the Province of Smyrna.

At one time the working of the chrome ore deposits of the Smyrna Province was carried on extensively, and proved to be highly remunerative. For a long period this Province supplied almost the entire requirements of the world in this mineral. The Smyrna ore contains from 40 to 55 per cent. chromic oxide. The annual production in chrome ore of the Vilayet of Smyrna varied between 7,000 and 15,000 tons. If the mines were properly and economically worked they night be made to produce from 50,000 to 60,000 tons per annum; but under present conditions it would not be possible to transport more than 15,000 to 20,000 tons. The lack of transport facilities within the Province also compelled mine owners to put a limit to their activity, as the charges incurred would not allow them to compete with ores of New Caledonia and Rhodesia. Construction of light railways may offer facilities for future development. In spite of the present inactivity, which may continue for a certain time in consequence of the high cost of labour and other difficulties, it is almost sure, says the United States Consul-General, that very important mining operations will be undertaken in this Province in the near future.

Kemikli Mine.—This mine is situated in the Kaza of Makri (Sanjak of Menteche) at a distance of 9 miles from the sea and 12 miles from the town of Makri. It consists of two distinct deposits—the Kesser-Ali and the Tumbachi. The Kesser-Ali deposit is formed of two pear-shaped masses lying in inverse directions; the grade is of 48 to 50 per cent. This deposit is located at the top of a hill; the ores extracted are conveyed to the Kizil-Dere River by shoots and are transported in carts to the washing plant at Imbachi. The other deposit of this mine consists of a vein from 6 to 13 feet thick, of vertical direction, and of a grade of 42 to 45 per cent. The work is carried on by shafts. Ore obtained at this mine is transported by caravans to Ichalish-Iskelessi, a small pier, whence it is taken by sailing boats to Mem-Pacha, on the opposite shore, to be shipped.

Katrandjik Mine.—This mine, situated near the seashore, consists of weak seams containing ore graded 40 to 42 per cent. Thus far it has not proved to be of importance.

Kodjek Ali Pasha Mine.—This mine is situated in the interior of Kodjek, Kaza of Yuksek Koumou, at a distance of 50 to 62 miles from the sea. It consists of seams 9 to 10 feet thick, the grade of the ore being 45 to 50 per cent. and the inclination 45 degrees. A great quantity of ore is available from this mine, which has not been worked for 20 years on account of the owner's reluctance to invest capital and to engage an engineer. The roads which lead to the seashore are in a very poor state.

The Hadji Nicola Mines.—Hadji Nicola owns many mines at a distance of 2 to 8 hours from the sea. The grade of the ore is from 40 to 48 per cent. and the work is carried on by quarrying as well as underground systems.

Patterson Mines.—These are from 4 to 12 miles distant from the sea and consist of very rich seams graded 40 to 52 per cent. Part of these concessions have been annulled and given to a certain Arif Bey, but Messrs. Patterson are taking the necessary steps for the restoration of the mines to their rightful owners.

Hadji Mehmed Mine.—This mine is quite near the locality of Makri, at a small distance from the sea. It consists of seams 6 to 7 feet thick with an inclination of 45 degrees and a grade of 46 to 50 per cent. It is not possible to give an idea of the real production of this mine as it has never been worked in a proper manner.

Besides the above-mentioned mines, there are other less important ones belonging to French, Greek or Turkish firms. No definite opinion can be expressed as to their real value, since they have been worked in the past with very primitive means. The grade of the ore obtained is from 42 to 48 per cent.

Chrome Mines in the Provinces of Adana and Konia.

In the neighbourhood of Mersia, near the village Elvanli, there are several mines of chrome which contain 50 to 51 per cent. of chromic oxide. As regards transport facilities, these mines are well situated. The ore is taken by mules to Toumouk, near Mersina, where there is a small pier to facilitate direct loading on steamers. The average annual production of

these mines can be estimated at 1,000 tons. This ore was exported to France and Germany. The other chrome mines of this Province are at present of no importance, as they have been only superficially explored. The lack of a port, of labour, and of roads are the three stumbling-blocks to the further development of the chrome deposits in this Province.

The chrome resources of the Province of Konia appear inadequate to allow further development. The average annual output of the chrome mine situated near Adalia is about 1,000 tons.

Mining Methods—Transport Difficulties.

In general, chrome is extracted by the quarrying system ; but galleries are resorted to, as well as inclined and vertical shafts, either to follow the eruptive vein or to attack the mass of rock beneath the surface stratum when the latter has been impoverished below the limit of profitable production. The usual method of extracting the mineral is the most primitive ; the tools used are limited to the pick and shovel, and when it is necessary to remove hard rock, which may be encountered in the drifts, the work is done with the hand drill and sledge hammer, while the blasting is done with ordinary coarse black gunpowder. There are no mechanical or compressed air drills in use in any part of Asia Minor.

The only transport available, in general, from the mines to the seashore or the railway station is that afforded by camels, mules, or donkeys. No properly built roads are maintained which are available for the beasts of burden ; they must carry their loads over the footpaths and tracks which meander down the mountain sides, and practically double the distance to be traversed. It would not be a difficult matter in the opinion of the United States Consul-General, to link up all the best mines by a common aerial cableway, like the one at Dagh-Ardi. This would very greatly simplify matters and be of enormous advantage from every point of view ; it would probably reduce the cost of transport 70 to 75 per cent. If an aerial ropeway were established it would be an easy matter to extend it later on to other valuable deposits farther inland, which have never yet been worked because the cost of transport exceeds the value of the ore.

Makri, from whence most of the ore is shipped, is safe and protected as a port ; but the greater part of the water is shallow, and it is only in the south-west part of the bay of Makri that the depth offers a good anchorage. Shipments are, therefore, made on small lighters carrying from 10 to 15 tons, which lighters have to be towed by a steamer from the port of Makri to the place of shipment at Ikinjik, which is only an open roadstead.

EMPIRE TIMBER EXHIBITION.

The Department of Overseas Trade is to be congratulated on promoting the exhibition of timber grown within the Empire which was opened at the Holland Park Skating Rink on July 5th and closes on the 17th. To many people the wide range of these timbers will come as a surprise. A large number are hardly known in the United Kingdom; but even a brief study of the exhibition will satisfy one that there is scarcely a purpose to which timber can be put for which the Empire does not furnish a suitable tree.

Practically every timber-growing country in the Empire is represented either by an official exhibit or a private firm, or both. The Dominions of Canada, New Zealand and Newfoundland, the Indian Empire, the Governments of Western Australia, New South Wales, Tasmania, Union of South Africa, the Administration of British Honduras, British Guiana, Ceylon, Gold Coast, Trinidad, Fiji, Nigeria, and East Africa Protectorate are all exhibiting.

Specimens are shown both in the rough and in the finished state, polished and unpolished—everything from the sawn log to the carved panel, from a lead pencil in cedar to a railway carriage in teak. A feature of the Western Australian exhibit is a panelled room and furniture made of jarrah (Western Australian mahogany or everlasting wood). The extraordinary durability of this wood is exemplified by various posts and rafters which show little sign of deterioration after periods of sixty years in the ground or roof as the case may be.

A particularly attractive section of the exhibition is that devoted to the timbers of India. Messrs. W. W. Howard Bros. & Co., agents for the Government of India, have been at great pains to show the practical possibilities of several unfamiliar timbers. In particular, attention should be called to the parquet floor and staircase of silver-grey wood, which has a delicate grey colour and a satin-like lustre; and still more to the billiard-room, which is panelled in laurel wood. This wood is of a golden to greyish-brown colour, with deep streaks and markings of a dark umber shade, and it has a bright metallic sheen on the surface when planed and polished. It is undoubtedly a very beautiful wood, and suitable for the finest decorative work. As it can be obtained in large sizes it is admirably adapted for panelling. Another attractive timber which is seen here to great advantage is Andaman padauk. This varies in colour from pale cherry to crimson and vermilion, and is generally streaked with darker shades which sometimes become a deep black. The texture is fine and hard, and the wood is extremely strong and durable. A railway coach built at the Great Eastern Railway Company's works is on view. It contains first- and third-class carriages decorated throughout in silver greywood and padauk respectively.

The exhibition should have important results for the home timber trade in making known the

resources of the Empire, and it is to be hoped that it will lead to the development of new sources of supply, the extension of established ones, and the study of a world-wide range of timbers.

NOTES ON BOOKS.

THE EVOLUTION OF BRITISH MEASURES. By Howard Wall. London: Talbot & Co.

This little book contains a good deal of interesting and curious information about the origin of British measures of length and the establishment of the British standards. Besides the essay, which gives a title to the book, it includes several articles on the Metric System, Foreign and Classical Measurements, etc., and an account of Dean, who popularised the use of measuring tapes and established a business for their manufacture in 1818. This business is still successfully carried on by the author of the book, Mr. Howard Wall. That Dean was not actually the first to produce measuring tapes is shown by a reference in the Society's *Transactions* for 1805 (vol. xxiii. p. 119) to such tapes by a writer who describes how he used one marked with inches on one side and feet on the other, for measuring the growth of trees. Such tapes were, he said, made by "Mr. Cary, optician, in the Strand." The mere fact that such a description should be given shows that the tapes were not generally known or largely employed. It seems a little remarkable that such a simple and useful device should not be able to have an earlier date assigned to it. It is possible that flexible tapes were occasionally used before this time, but it appears certain that they were not generally known or employed until Dean started their manufacture. They then came rapidly into use, and are now, of course, of universal application. Probably the latest development, and that is not very recent, is the flexible steel tape which forms such a convenient pocket measure.

Those who are interested in the subject of measurement may be referred to the excellent paper on the Metric System read before the Society in 1906 (*Journal*, vol. lv. p. 50) by the late Sir Charles Watson. It contains a very complete history of the origin of the French metre.

GENERAL NOTES.

THE FAR EASTERN MATCH TRADE.—At one time, says the *Colonial Journal*, the match trade in the Far East was largely in the hands of Swedish exporters, though a small portion of the supplies came from the United Kingdom. In the early nineties Japan took up the manufacture of matches for export, and in a very few years established such an ascendancy that British matches disappeared from the Eastern market and the Swedes were almost in similar case. Japan has at present a virtual monopoly. A British company has, however, been formed in Kuala Lumpur, the capital of the Federated Malay States, with the object of founding a match factory in the neighbourhood. Tests have been made of woods found in the forests of the Malay Peninsula, and it has been ascertained that suitable supplies can be secured for the manufacture of matches. Machinery has been ordered from England, and British Malaya will be given a new industry which promises to become one of considerable importance.

CUTLERY RESEARCH ASSOCIATION.—The [illegible] Association for the Cutlery Industry [illegible] approved by the Department of Scientific and Industrial Research, as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The Secretary of the Committee engaged in the establishment of this association is W. H. Bolton, Esq., P.O. Box 49, Sheffield.

THE FALKLAND ISLANDS.—A very remarkable case of trade development is shown by the statistics of the Falkland Islands. In 1908, according to the *Colonial Journal*, the imports were of the value of £73,062, the exports £189,972. In 191[illegible] the figures were £939,937 and £2,054,286, although [illegible] shipping was so scarce that only six vessels [illegible] the colony. The products are practically limited to wool and whale oil, and it is to the rise of the latter industry that the increase is mainly due.

HONG KONG CAMPHOR TRADE.—The shortage in the supplies of camphor, according to the Consul-General at Hong Kong, due to the much reduced output of Formosa (Taiwan) and the greatly increased demand during 1919, has resulted in a boom in the trade in Hong Kong. Exports of camphor from Hong Kong to the United States in the earlier months of 1919 were too small to be separately noted in the trade returns. The total exports from the colony for the first quarter of the year amounted to only 54,810 dols., at normal sterling exchange; the value in the second quarter rose to 233,954 dols. In the first quarter nearly the whole of the exports went to India, the Straits Settlements taking about 10 per cent. of the total. In the second quarter India continued to take some of the output, but the United States commenced to draw upon the South China stocks, taking exports to the value of 181,550 dols. Since then the export of the gum to the United States has steadily increased, the value of such exports for July reaching 176,900 dols.; those for August being valued at 208,641 dols., those for September at 360,641 dols., and those for October at 606,940 dols. Thus the total exports of gum camphor to the United States during the first ten months of the year amounted to 1,534,672 dols. The comparatively favourable price of the Hong Kong gum accounts in part for the strong demand.

Journal of the Royal Society of Arts.

NOTICES.

COLONIAL SECTION.

A meeting of the Colonial Section Committee was held on Friday, July 16th. Present:—

Lord Blyth (Chairman of the Section); A. H. Ashbolt; Lieut.-Col. Sir Charles H. Bedford, LL.D., D.Sc., M.D.; Byron Brenan, C.M.G.; R. E. Brounger; Hon. Sir John A. Cockburn, K.C.M.G.; and W. L. Griffith, with S. Digby, C.I.E. (Secretary of the Indian and Colonial Sections).

PRICE OF THE JOURNAL TO NON-FELLOWS.

In consequence of the enormously increased cost of printing, paper, etc., the Council have found it necessary to raise the price of the *Journal* to non-Fellows of the Society to One Shilling.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION..

THE IMPROVEMENT OF CROP PRODUCTION IN INDIA.

By Albert Howard, C.I.E., M.A., F.L.S.,

Imperial Economic Botanist to the Government of India.

(*Continued from page* 564.)

Drainage.—The third application of the soil-aeration factor relates to inadequate drainage. The essence of drainage from the plant's point of view is not the removal of water, but the maintenance of the oxygen supply of the soil water. In the case of ordinary crops like wheat, all that is necessary to bring this about is an adequate gaseous exchange between the atmosphere and the pore spaces. In water culture, of which rice is perhaps the best agricultural example, it is essential that there should be a very slow movement of oxygenated water round the feeding roots. Over large areas of India nourished by the monsoon, imperfect drainage bars progress. In the plains of India, defective surface drainage arises from two causes. In the first place, when the soils are on the stiff side, local surface accumulations of rain water rapidly lower the fertility. In the second place, the subsoil water often rises to such an extent, at a time when the flow of the rivers is impeded, that little or no general drainage is possible over large tracts. These two aspects of the subject will be considered separately.

Surface water-logging is very common in India during the rains. Any holding up of the surface drainage by irrigation channels, by embankments of various kinds, or by any slight concavity of the fields due to the misuse of iron ploughs, invariably leads to poor, weak growth, which exhibits all the characteristics of nitrogen starvation. That the loss of fertility is largely due to de-nitrification is shown by the results of an experiment carried out at Pusa in 1910. In that year, a plot of heavy land was purposely water-logged during the month of September in order to compare its behaviour with normally managed land on either side. Across the middle of the plots, a strip was manured with four cwt. of nitrate of soda to the acre just before sowing the wheat. The results are given in Fig. 1, from which it will be seen that the effect of a month's water-logging was to reduce the yield of wheat by about sixteen bushels to the acre.

Normal cultivation.	Water-logged during September.	Normal cultivation.

34·45	15·55	29·14

Fig. 1.—The Result of Water-logging Wheat Land at Pusa in 1910.

The numbers in the plan are bushels per acre.

De-nitrification is not the only consequence of surface water-logging. The physical texture of the soil is profoundly affected, and when the land dries it is difficult to obtain the ideal crumb structure. The clods do not readily break down under the beam and the soil is gummy to the feel. Colloidal substances appear to be formed under these anærobic conditions which not only hinder the formation of a good tilth, but also prevent percolation.

The remedy for surface water-logging is better drainage. A method of surface drainage has been worked out at Pusa (Plate III.) which has led to improvements in fertility and in the ease of cultivation which are almost past belief.

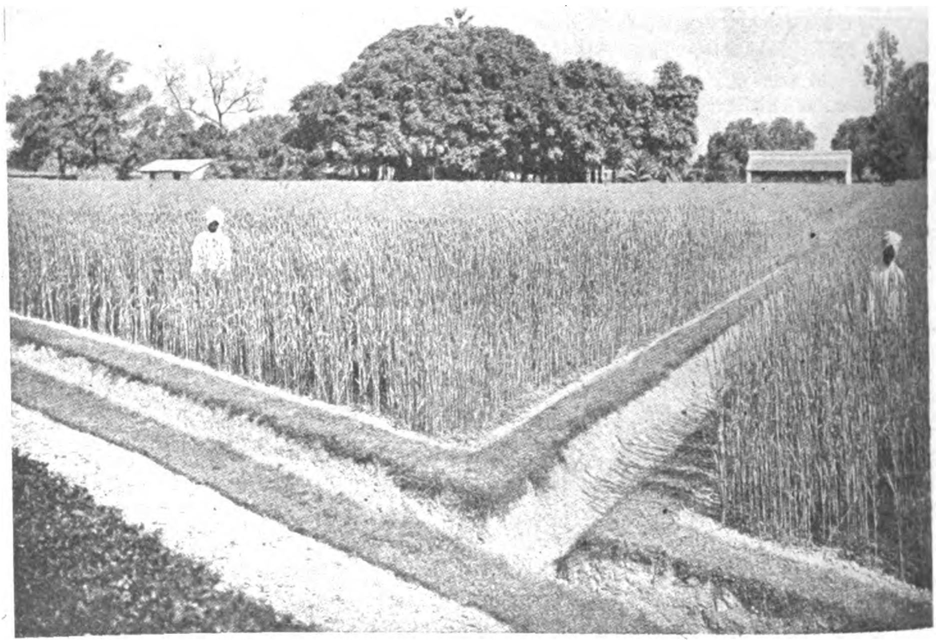

PLATE III.—SURFACE DRAINAGE AT PUSA.

This method consists in dividing up the area to be drained into units not more than four or five acres in extent, separated by trenches. These trenches are about four feet wide and two feet deep, with sloping sides and grass borders. The run-off passes over these grass borders and is led away to low-lying rice areas, while most of the fine silt is retained on the field. By this device, each field has to deal with its own rainfall only and the run-off is strictly controlled.

The Botanical Area at Pusa has been transformed by improving the surface drainage. The yields have increased, the plots produce even crops, and the tilth of the stiffer areas, which was formerly poor, is now greatly improved.* Several of the indigo estates in Bihar have adopted this system, which the surrounding cultivators are now copying.

The prevention of drainage during the rains occurs in the plains of India towards the delta of the Ganges after the flow of the rivers is checked by the inundation of Lower Bengal. The rivers overflow and the low-lying areas go under water. The rise in the level of the rivers is followed by a rise in the water level of the wells. These movements of the river levels and of the general ground-water are illustrated in Plate IV. The curves are typical of the subsoil water conditions of North Bihar during the rains. These ground water and river level curves have proved to be of particular interest

* The experience obtained in the Botanical Area at Pusa during the last fifteen years throws considerable light on the nitrogen problem in India. Surface drainage, by checking erosion and by reducing de-nitrification in the rains, has had the effect of increasing the fertility with a comparatively small expenditure of organic matter. For example, Plot 10 has, during the last fifteen years, produced thirteen heavy cereal and two good pulse crops, while the manurial treatment has consisted only of three crops of green manure and a single dressing of castor cake at the rate of half a ton to the acre. The land has improved under the treatment, and in 1919 gave a record crop of wheat of over forty bushels to the acre. Similar experience has been obtained at Quetta, and on several of the farms in the United Provinces. These results suggest that nitrogen fixation is much greater in the plains of India than is commonly supposed.

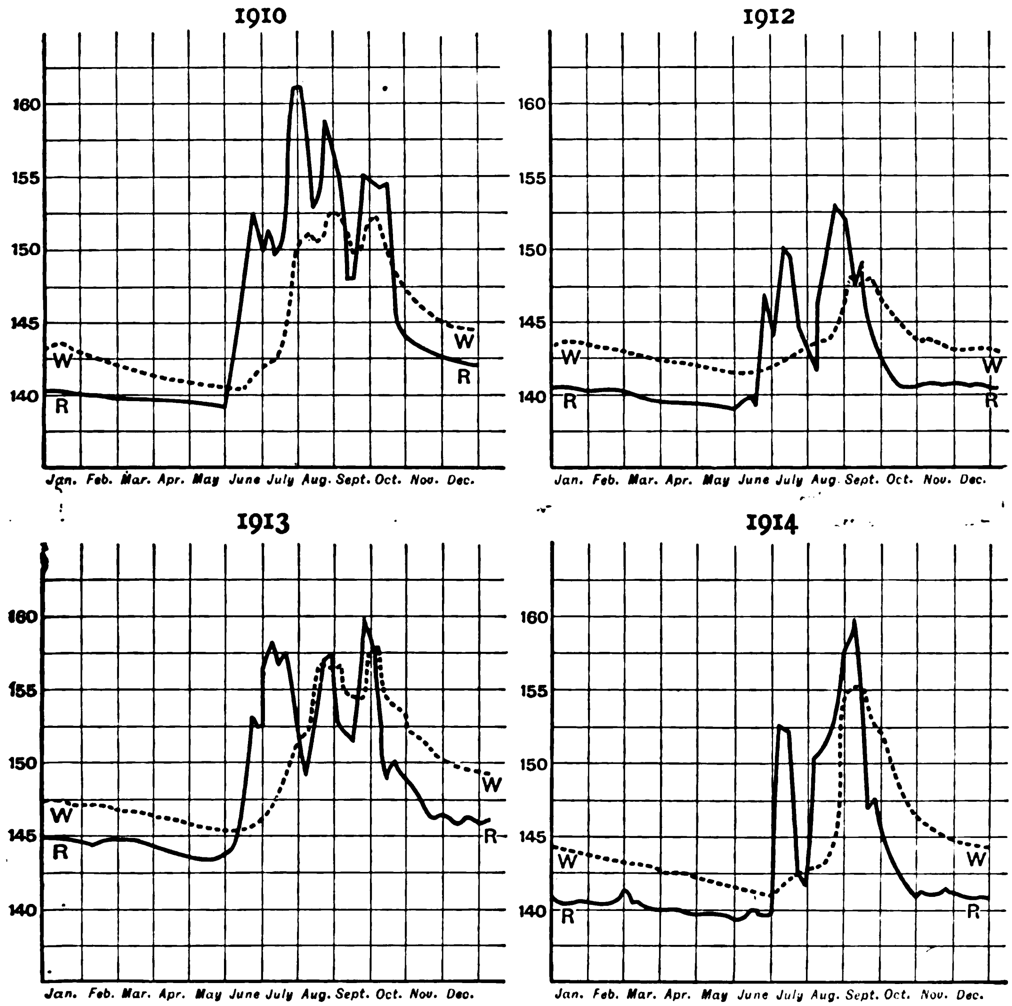

PLATE IV.—CHANGES IN THE RIVER AND WELL LEVELS AT PUSA.
The well levels are shown by dotted lines.
The observations are expressed in feet above mean sea level.

in the study of the root systems of the various crops grown and of some obscure plant diseases. Soon after the ground water rises in July, the absorbing roots in the lower levels of the soil die off, while those in the surface soil exhibit marked aerotropism in some cases, leaving the soil altogether and running over the surface of the ground. Deep-rooting crops of all kinds suffer from wilt, while surface-rooting crops escape (Fig. 2, p. 572).

The varieties of *H. Sabdariffa* (Roselle) have a superficial root system and the absorbing roots are markedly aerotropic. They thrive in the wettest years. Most of the types of *H. cannabinus* are deep-rooted, and these lose their absorbing roots after the soil water rises, and always suffer from wilt. Only one variety of this crop is surface-rooted: this thrives exceedingly well in the plains. Many other similar cases have been examined. In every instance surface-rooting varieties thrive in the rains in North Bihar, while the deep-rooted kinds without exception suffer from wilt diseases.

While the cultivator can often do a certain amount to improve the surface drainage of his fields, he is quite unable to cope with the larger aspects of the subject. Observations indicate that in many parts of India the surface drainage of large areas is defective and the crops suffer from poor soil-aeration. In some cases, this is due to the existence of extensive, shallow, cup-shaped depressions which are unable to discharge the run-off quickly. In others, the general surface drainage is partially held up by roads, by embankments, and by bridges provided with insufficient water-way. Such problems are

clearly beyond the means of the zamindar. They need for their solution the services of the engineer. A detailed drainage map of the area to be improved is obviously the first condition of success. From an inspection of some of these areas in the plains it would appear that a great deal could be done by the provision of a system of drainage canals by which the run-off can be passed either into rivers or led slowly through rice areas at a slightly lower level.

The difficulty in matters such as these is to make a successful beginning. The first step appears to be the study of the general drainage of a few of these partially water-logged tracts of the alluvium, the preparation of a drainage map combined with a study of the rivers where this is necessary. The drawing up of definite working-plans would follow, and progressive landowners would probably be found who would be willing to execute a small project under direction. These proposals do not involve a great deal of expense. A certain number of engineers with the necessary agricultural insight in all probability exist in the country now and, if set to work on this question, would rapidly justify themselves. Their assistance in this matter is essential. The cultivators and zamindars are so intent on their own small areas of land that they cannot be expected to evolve a scientific scheme of drainage for the country-side. Clearly it is for the State to provide a directing hand. In this direction a step forward has already been made by one Indian Province. In the *Punjab Government Gazette* of September 28th, 1918, the constitution and duties of a Drainage Board for the province were announced. In the Government [illegible] on this matter it is stated that "water-logging is due to many other causes than seepage or over-irrigation from canals, for instance, imperfect natural drainage or the obstruction of natural drainage by roads, railways, irrigation channels and zamindars' embankments. The evil is of steady growth in parts of the province and in some places threatens not only the prosperity, but the health of the rural population and involves also serious loss to Government revenue. Hitherto it has been dealt with only spasmodically. There has been no settled policy either for investigation or for action. The question should, therefore, now be taken up for the province as a whole."

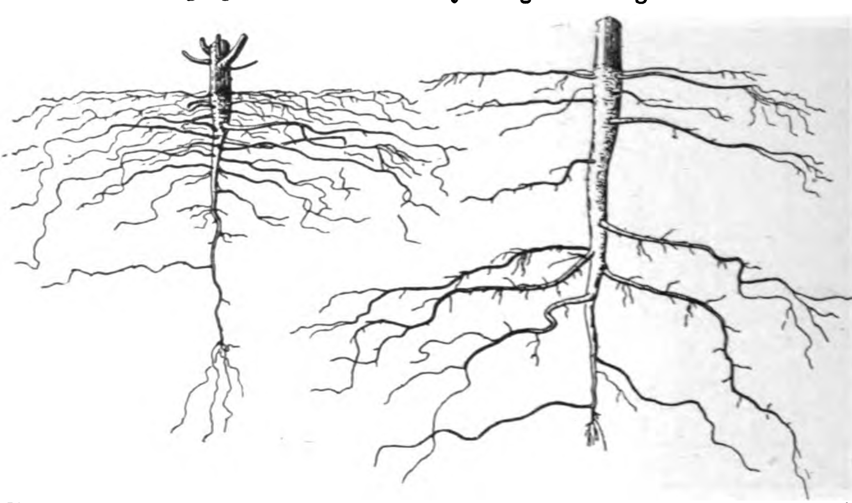

FIG. 2.—THE ROOT SYSTEM OF *Hibiscus Sabdariffa* (LEFT) AND *H. cannabinus* (RIGHT).

SOIL TEMPERATURE.

The investigation of soil temperatures is also yielding interesting results in India. As is well known, crops will only grow between definite limits of temperature. In Great Britain, the lower limit is most important; in India the reverse is the case and the higher limits affect growth more frequently. We see the effects of this factor at work on the large scale in the separation between the cold season and monsoon crops in Northern India, and in the geographical distribution of crops like gram (*Cicer arietinum*, L.). A line drawn from Bombay to Patna separates those portions of India where this crop is most important from those where it occasionally occurs. North of this line, the temperature in the cold season is much lower than in the south.

A most interesting case of the effect of soil temperature on growth has been worked out in Bihar, where one of the difficulties attending the cultivation of wheat has been found to arise

from a high soil temperature at sowing time. It frequently happens that the late monsoon rains fail and the onset of the cold weather is delayed. In such years, the soil and particularly the subsoil remain at a comparatively high temperature for some days after the usual sowing time of wheat. If the crop is sown at the usual time in such seasons, it germinates, but the seedlings do not thrive and are attacked and destroyed by white ants. The seedlings disappear from whole fields in a day or two, and over the countryside the wheat crop is wiped out. If the crop is re-sown at a later date on the same land it grows normally and practically no damage by white ants takes place. Investigations have shown that the cause of the damage is not the white ant, as is sometimes supposed, but the high temperature of the subsoil, which leads to the partial destruction of the root system of the seedlings. Afterwards, the white ants devour the sickly plants. The remedy consists in lowering the soil temperature by leaving the furrows open for a couple of days so as to cool the soil by evaporation, and by postponing sowing by about a week in such seasons.

As can readily be imagined, the investigation of problems of this nature, which may be termed exercises in applied physiology, are, perhaps, the most interesting which fall to the botanist in India. I trust I have been able to show that they are well worthy of further study and that they are certain to lead to results of great economic importance.

IV.—The Future of Economic Botany in India.

Up to this point the lines of advance in crop-production in India through the plant have been dealt with. At the same time, the wide range of the problems presented by the country has been indicated. The problems are obviously complex. Their solution involves a knowledge of science, of practical agriculture, and of trade requirements, as well as the faculty of combining these very different points of view. The country is large and the questions still to be attacked are very numerous. The mere size of the country and the large areas under any particular crop mean that even a small improvement in the yield per acre, when multiplied by the area to which the improvement applies, soon runs into lakhs of rupees.

What is the best means of getting such work done? The State is anxious that the volume of results should be increased. Should we rely on organisation, or should we trust to the individual? Both systems have their advocates. The answer, I think, is given by experience and by history. All notable advances in agriculture up to the present time have been initiated by individuals and not by systems of organisation. This applies to creative work of every kind. The individual has always triumphed over the committee or the organisation. Further, all organizations sooner or later become affected by disease. In India, this often takes the form of acute departmentalism.

What are the qualifications of the men who are to carry out the work? I think the subject to be investigated supplies the answer. The men must obviously be more than laboratory workers. They must look at the questions from three points of view—that of the scientific investigator, that of the cultivator, and that of the trade. Science is the instrument by which the advance is made. A first-hand knowledge of practical agriculture and the cultivator's point of view suggest the problems to be attacked. The uses to which the final product can be put or in other words, the requirements of the trade, gives the direction in which the advance can be most profitably made.

DISCUSSION.

The Chairman (Sir Robert W. Carlyle) said a letter had been received from Sir Daniel Morris expressing his regret at not being able to attend the meeting, and in that letter he wrote with regard to crop production in India:—"The work he (Mr. Howard) has done in this connection is of great value, not only to India, but to the whole Empire, and well illustrates the importance of enlisting the highest resources of science in the development of tropical and sub-tropical industries." It was, Sir Robert Carlyle continued, to the Howards that India owed the Pusa wheats, and it was quite possible that in the future even more important results might be obtained in the direction of reducing the waste of water. A beginning had been made, by Mr. Howard and others, of great importance in that matter, and, by dealing with the cultivators in villages as a whole, it might be possible in time to introduce a system of supplying water by measurement even on old irrigation canals. However that might be, it was most desirable that attempts should be made to introduce such a system in all new irrigation works. He was not quite sure that he followed the remarks on the future of economic botany in India. He agreed that the first thing was to secure ability combined with experience and that ability should be given a free hand, but organisation was indispensable in order to secure that the results obtained by the botanist were made use of by the cultivator.

Sir Claude H. A. Hill, K.C.S.I., C.I.E., said it was a great privilege to him to associate himself with what had fallen from the Chairman with respect to Mr. and Mrs. Howard. There were present at the meeting three fellows of the Society who had at one time or another been in charge of agriculture in India, covering a period of fifteen years, and during the whole of those fifteen years they had known and appreciated most highly the invaluable work done by Mr. and Mrs. Howard. With regard to what was said in the paper about standardisation from the industrial point of view, a good deal had been already done in the way of improving the quality of the produce of India, especially wheat and cotton. It was largely due to the efforts of the Howards that Indian wheat stood upon a wholly different footing to-day in European markets from that upon which it stood ten or fifteen years ago. As to cotton, the Committee which recently sat in India recommended that an endeavour be made to control the admixture of seed by establishing a system of licensing ginneries. It was in the gins that that mixture of seed had taken place. The Government of India had determined to act upon the Cotton Committee's advice and introduce a system of licensing. In connection with wheat there was a supplementary subject of very great interest and importance to the development of the industry. He alluded to the treatment of wheat commercially. It was becoming increasingly evident that India was seriously behindhand in that matter. During the war in one year nearly 2,000,000 tons of wheat were exported to the Allies, practically the whole of that export going from the port of Karachi, and being exported on a completely antiquated system. The normal exports amounted to less than 2,000,000 tons a year at present, but were bound, under the stimulus of improved production, to increase and to keep ahead of the increased consumption which was also taking place in India in substitution of other less nutritive grains. Unfortunately there was not a very strong public opinion to give expression to those views, but such opinion as existed was growing steadily in the direction that elevators must be introduced, and experts insisted that they must be introduced at first in the ports. It followed that the Karachi Port Trust must at no distant date adopt such a system. Last year the Government of India addressed the Bombay Government on the subject, and invited the urgent consideration of the matter by the Karachi Port Trust. Up to the time he left India recently no reply had been received, but it was quite natural that there should be some hesitation on the part of the Port Trust because, owing to the climate of Karachi, it was found to be exceedingly profitable to store the wheat on the open quays or leave it in trucks. That course was not in consonance with modern requirements, and it was earnestly to be hoped that the local Port Trust and the Government of Bombay would, at a very early date, enter upon the larger policy of expansion for Karachi. Mr. Howard had spoken of the reluctance of the cultivators to adopt new methods. Everyone present appreciated the fact that India over very large areas was tilled by small cultivators, who were practically proprietors of the soils and whose holdings sometimes ran to even less than an acre. Under such circumstances it was easy to conceive the difficulty an Agricultural Department had to face in inducing cultivators to adopt improvements, although the cultivator himself was a thoroughly intelligent person, and would, directly a thing was shown to be profitable, endeavour as far as possible to follow it up. The experience of a thousand years had taught him the exact limit up to which he could produce crops from the land without deterioration of the soil. Consequently he was very apprehensive of any intensive cultivation which he knew would, unless he was able to replace the wastage of the soil, result in soil deterioration. In Oudh some of the Zemindars had given up considerable areas to the production of pure seed, and the same thing had occurred in the Province of Agra. With reference to the suggestion of a development fund, he was not quite certain what Mr. Howard meant. A great deal had been already done by the development of co-operative credit societies for the purchase and distribution of grain, and hitherto there had been an inclination to hope that that was the line of development which would produce the best results. He did not know how Mr. Howard proposed that the development fund should be organised and financed. On the question of encouraging the production of improved seed in India, the Government had recently been considering the question of bringing into being an Agricultural Society on the lines of the Royal Agricultural Society in England. He had the pleasure of meeting on this matter the President and the Secretary of the Royal Agricultural Society last year, and he received the very greatest help and encouragement from them. Quite rightly, agriculture was to be one of the "transferred subjects," but if some stimulus was not applied there was a risk that Provincial Legislatures might hesitate to sanction the necessary expenditure. There could be no better stimulus than that which would be afforded by an unofficial Society of wide influence, commanding large funds. A conference to discuss the subject was to be held in Simla this summer. Mr. and Mrs. Howard had done excellent work in trying to effect water economy in India. It was not an easy matter to subvert the whole of the system on which the Irrigation Department of the Punjab had been organised, but he felt

certain that nothing but good could come of the further investigations now being made. He would like to claim for the Department of Agriculture in India that it had, considering all things, achieved considerable success. Cultivators in the remotest parts of the country now came to the Agricultural Stations dotted all over India, and, as far as their resources permitted, endeavoured to effect the improvements they had seen demonstrated. It was hoped that things would go ahead now on a very large scale in the matter of strengthening the Department, especially on its scientific side. Individuality was absolutely essential, but he could not see that it had been demonstrated, as was suggested in the paper, that organisation was relatively unimportant. He hoped the view would prevail that organisation was absolutely essential to the proper utilisation of the skill of the individual. Mr. and Mrs. Howard were now going to a sphere where individuality would have the fullest possible play, namely, to a new plant industry institute in Central India. Knowing what they had been able to do at Pusa, there was no doubt that they would achieve great things in the future, and he felt confident that the results of the work they would undertake in their new station would be carried through in co-operation with and to the great benefit of Pusa.

DR. J. A. VOELCKER said that Mr. Howard had shown in his paper what an enormous field there was for inquiry in the future in connection with the special science of economic botany, and had made it very clear that the inquiry was not only a large one but one which must be very systematically pursued. It involved the study of the requirements of India and of each place in India and of the various conditions which prevailed, and demanded something more than the individual cultivator could provide. The Indian cultivator, he thought, made better use of his facilities than the cultivator in this country made of his, but the selection of seed and the trying of new varieties was something beyond his power, and a well-organised department, such as the Agricultural Department, must be called in to help. It was satisfactory to learn that the excellent work which had been done was beginning to be appreciated by the cultivator. In the Report which he himself made he ventured to suggest the importance of extending the work of seed distribution and seed selection. There had been a certain amount of work done at Cawnpore and in the Bombay Presidency, but time was needed, and he was glad to hear that an extension of that work had since been carried on. Great care was needed in coming to definite conclusions with regard to seed selection and distribution, as it was not one condition alone that determined whether a fresh variety or a fresh kind of seed should be sown, but a consideration of a number of conditions, and it was in that direction that a well-organised department could assist. It was not an easy thing to get good quality combined with good quantity, and even in this country he did not think there had been any marked success in getting a wheat which would produce the yield of recognised varieties and combine the quality of hardness that was found in Canadian and other wheats. The extension of seed farms was most desirable. He would like to know whether the difficulty of the cultivator in getting an improved kind of seed still existed. About 1890 the real difficulty was for the cultivator to get out of the hands of the Banyas, on whom, at that time, the cultivator was almost universally dependent for getting his seed. Another very important branch of the subject was the question of nitrogen, and he did not think that the real solution of the question had yet been found. It struck him, on examining the soils of different parts of India, that they were very poor in certain respects, chiefly in regard to nitrogen. There was also the important point of the physical condition of the soil. Physical conditions in agriculture were quite as important as, if not more important than, the chemical conditions, and what Mr. Howard had said about the importance of paying attention to the amount of water and to the results of using water he could fully confirm from what he had himself seen and studied. Over-irrigation, producing water-logging, was apt to bring up injurious salts in the soil, and when heat followed, it produced a clogging of the land which was inimical to proper aeration and to the circulation of oxygen through the soil. As an official of the Royal Agricultural Society and as one who had gone out to India under their auspices, nothing would delight him more than to see an Indian Royal Agricultural Society; and any help the British Society could give to the Indian Government or the cultivators would be at their disposal.

SIR JOHN O. MILLER, K.C.S.I., moved a vote of thanks to Mr. Howard for his interesting and instructive paper. The paper was something more than merely instructive and interesting in a conventional sense; it was a very valuable contribution, especially the first part of it, on account of the spirit with which it was instinct, the only spirit in which he thought economic work could be carried out in a country like India for the benefit of the people. Mr. Howard said that the solution of the problem he had to deal with involved a knowledge of science, of practical agriculture, and of trading requirements, but in his paper he had shown that there was yet another factor to be considered. He had not allowed his investigations into the aspects of the elements of plant nature to obscure the

importance of human nature itself. It was no use producing agricultural products that were the best in themselves unless they could be also produced in such a way that the cultivator could make use of them. The Howards had achieved actual practical success in India such as perhaps had fallen to the lot of few. Mr. and Mrs. Howard once went to Quetta to assist fruit cultivation there, and found that, while there was room for improvement, the problem of immediate practical importance was to find a market for the excellent fruits already produced. For this reason, while their more scientific investigations were maturing, they set themselves to the prosaic task of making fruit boxes. That was an example of the practical spirit which had always characterised their work. It was a matter of great satisfaction that a scientific agriculturist had now come to strengthen the hands of the irrigation engineers in dealing with the problem of waste and misuse of water. The question of charging for water by volume was a very difficult one; but although it might take a long time to accomplish, that was the direction in which progress was likely to be made.

SIR VALENTINE CHIROL, in seconding the motion, said that amongst many varied experiences during his visit to India as a member of the Royal Commission on the Public Services of India, there were few that made such a lasting impression upon him as the visit he was privileged to make to Pusa, where he made the acquaintance of Mr. Howard. Although an absolute ignoramus in such matters, he was able to see in that institution a very valuable new organism for bringing the achievements of modern science within reach of the actual needs of the great agricultural population of India. He believed it was really providential that an institution of that kind for developing the agricultural productivity of India should have been founded in time to help us to face the present crisis, when one of the most serious questions with which the whole world was confronted was the shortage of agricultural produce, and that Pusa had been able to prepare India to fill up much more than it might otherwise have done the great gap which the devastations of the war had left in the production of foodstuffs.

MR. A. B. BRUCE, I.C.S. (Ministry of Agriculture), in supporting the motion, said it was desirable that people in India should realise what the reputation of the Howards in this country was. There could be no question whatever that the achievement of Mr. and Mrs. Howard ranked as one of the very greatest in the history of the application of science to practical agriculture. The only achievement that was at all comparable with their work was when science discovered artificial manuring, which, by introducing intensive farming, really revolutionised agriculture. He thought Mr. Howard would agree that the inspiration of the methods he employed came from the school associated very largely with Cambridge and the name of Bateson. The work of the Howards in India was an inspiration to workers here, and he hoped would in time lead to the adoption of better varieties in this country.

MR. J. S. BERESFORD, C.I.E. (late Inspector-General of Irrigation), in supporting the vote of thanks, said the improvements in irrigation in India had raised the value of crops enormously, and no doubt the value had been raised still higher by the selection and distribution of seed. It would be of interest to know whether recent developments had led to an increased yield of Egyptian cotton where tried in Sind. In Egypt the average yield was 600 lb. of ginned fibre per acre, the crop being sown in drills, and ten to twelve times depending on locality. With regard to drainage of water-logged soils and the illustration shown by Mr. Howard, he would like to know the distance apart of the drains and their depth. Regarding the experiment at Pusa in 1910 on a strip of land that had been intentionally submerged during the month of September, he could mention places in India and elsewhere that did not suffer from being long submerged. A notable instance was the successful basin irrigation in Egypt, where every year over one million acres of land, varying in character, was purposely flooded to a depth of 3 to 5 ft. during August and September, and the winter crop sown piece by piece on the saturated soil as the water was drawn off. He had had a great deal to do with making observations between rivers, especially the Jumna and the Ganges, where the level of ground water was not influenced by that in the rivers, but depended on the rainfall. The level rose gradually during and after the monsoon, attaining the maximum height about the end of December. The rise and fall were plotted in diagrams similar to those shown by the author. The results given in Tables 1 to 5 of the paper were valuable as showing what was possible under a special system of cultivation, and this on a small scale that admitted of close expert supervision; but he did not think the system was applicable to the vast areas of winter crops as ordinarily cultivated which had to be dealt with in practice, especially in years of deficient rainfall. Irrigation engineers had, during the last forty years, made numerous experiments in various directions with the view of economising water to the mere requirements of useful cultivation, and knew the obstacles in the way of this end. The best crop of wheat he had ever seen was on the Chenab Canal in 1897, when the supply of water was greater than the demand; the crop had been given eleven waterings, and the yield in grain was

found to be over 61 maunds per acre. Mr. Howard was no doubt well acquainted with the experiments carried out in America by King and others to ascertain the quantity of water required in the irrigation of various crops according to yield. Very often not more than 30 per cent. of the water from the head reached the field, and that was one of the difficulties in connection with selling water by measure.

The motion was carried unanimously.

MR. HOWARD, after acknowledging the vote of thanks and the many kind references which had been made to his work and that of his wife, said that in all research work the pioneer, the man who had to find his way into the unknown, should be unfettered and allowed to work out his own salvation, but when he had found, results, he agreed with Sir Robert Carlyle and Sir Claude Hill that organisation should come in and make use of them. With reference to the question of finance, he did not refer to the general financing of seed amongst the people, but to the difficulties which members of the Agricultural Department had in financing the seed they controlled and the seed occasionally bought from cultivators. It would be a great help if there was a development fund, because the Deputy Director of Agriculture was hampered by the existing account rules. The work went on continuously, and often involved credit, and it was necessary to have a running account and not an account which closed each year. In connection with nitrogen, several chemists in India thought there was an enormous amount of fixation by the soil organisms in addition to the fixation by leguminous plants, and that matter was being investigated. It was found in practice that if the supply of organic matter in the soil was kept up, it was possible, without the slightest fear of exhausting the land, to grow large crops of improved varieties, and there had been now fifteen years' experiments on that point. With regard to the amount of wheat that could be grown on one irrigation, the last result at Quetta showed that thirty-two maunds of grain were obtained with one watering, and Quetta was one of the driest places in India. Provided the soil was properly managed, it was remarkable how little irrigation water was needed for ripening large crops of this cereal. The illustrations of the drains shown referred not to the drainage of water-logged soils but to the control of surface drainage. In reply to Dr. Voelcker's question about the difficulties of supply of improved seed to the cultivators, these still existed and the demand was almost always much greater than the supply. This matter was now being dealt with in India as rapidly as the resources of the Agricultural Department permitted.

BRITISH COTTON-GROWING ASSOCIATION.

The annual report of the British Cotton-Growing Association for the year 1919 describes the work carried out by the Association in the development of cotton growing in India and the Colonies. It is hoped that the proposal to lease 7,500 acres in the Montgomery district of the Punjab Province, in order to demonstrate the possibilities of cultivating improved types of cotton, may be carried out in time for operations to begin in 1921.

Substantial progress is being made in cotton growing in Rhodesia and South Africa, where the industry seems likely to become established on a permanent footing. Efforts are being made to improve the staple, and a prize scheme has been inaugurated to encourage planters to cultivate the best varieties on a more extensive scale.

The Sudan Government Loan for £3,500,000 for developments, including railways, irrigation, etc., was successfully issued during the year.

The possibilities of Mesopotamia are discussed, and it is stated that experiments have established the fact that the country offers immense possibilities in cotton growing, the yield per acre in many cases being higher than is obtained in any other part of the world. The Council of the Association have decided to send out a ginning plant, and to begin direct operations without delay.

The report adds that when the necessary extensions and improvements in transport facilities, etc., have been carried out in Nigeria, Uganda, Sudan, and Nyasaland, a steadily increasing quantity of cotton will be produced in those districts where it has been proved that cotton, eminently suitable for Lancashire spinners, can be grown on an extensive commercial scale. The importance of this is emphasised by the fact that not only does the growth of American consumption show the urgent necessity of extending cotton-growing areas in British territory, but the mills of the United States are taking larger and larger quantities of the Egyptian crop.

THE MALAY PENINSULA.

Some interesting information is contained in a short article on the Malay Peninsula in the *Empire Mail*. For many years the Peninsula has been the chief source of the tin supplies of the world. It is also the principal rubber-growing country; and it was recently stated by Sir Frank Swettenham, a former Governor of the Straits Settlements and High Commissioner of the Malay States, that there is upwards of £100,000,000 of British capital invested in the plantation industry in the Peninsula.

INCREASING TRADE.

At one time it produced sugar and coffee in large quantities, but nowadays the export of both is negligible. Copra, tapioca, areca nuts, indigo, spices, gums, gutta percha, gambier, rattans and canes, raw hides, tungsten and scheelite are amongst the exports of the country; but tin and rubber are

the mainstays of its trade and have brought it prosperity. Some idea of the extent of the trade may be learned from the value of the imports and exports passing through the Straits Settlements—Singapore and Penang being the principal ports of the Peninsula. The following figures show the value of the trade in 1918 and 1919:—

	1918.	1919.
Imports . . .	£89,446,602	£107,453,544
Exports . . .	80,722,501	110,981,637
Total . .	£170,169,103	£218,435,181

After making due allowance for the increase in values of goods all over the world, it must be admitted that the above figures represent a considerable volume of trade. With the development of the country and an increase in its exports, there must necessarily be a growing demand for manufactured imports, for there are few local industries on a large scale and most things have to be imported from abroad.

Better known to-day than it was a quarter of a century ago, there is still a good deal of ignorance as to the political divisions of the Malay Peninsula. That portion of it which comes under British control and administration may be divided into three categories—the Colony of the Straits Settlements (which include Singapore, Penang and Province Wellesley, Malacca, and the Dindings); the Federated Malay States (Perak, Selangor, Negri Sembilan, and Pahang); and the Native States of Johore, Kedah, Perlis, Kelantan, and Trengganu. The Governor of the Straits Settlements (at present Sir L. Guillemard, K.C.M.G.) is also High Commissioner to the whole of the Malay States, and resides at Singapore. The Federated Malay States, whose Federal capital is at Kuala Lumpur, in Selangor, has a Chief Secretary (Sir E. L. Brockman, K.C.M.G.) and a Federal Council, and there is a Council in each of the four States, with a British Resident. The administration of the Colony and of the Federated States is staffed with Europeans, and the connection with the Colonial Office in Downing Street is a close one. In each of the other Native States there is a British Adviser, whose advice is followed by the native rulers.

Transport Facilities by Rail and Road.

The opening up of the Peninsula has been rapid since the British authorities undertook the supervision of its internal affairs. There are over 1,000 miles of railway, the British system being now connected with the Siamese and giving quick transit between Singapore and Penang with Bangkok, the capital of Siam. There are over 3,000 miles of road, unrivalled in the tropics and suitable for motoring.

Since their federation, the Malay States have advanced enormously in civilisation. In 1875, the aggregate value of their trade was only £297,882; in 1905, it was £13,471,539; in 1915, £26,106,872; and last year (1919), £40,550,000. The value of the tin exports was £8,745,635 and of rubber £22,059,244. Johore has made great progress during the past ten years. It is largely agricultural, with rubber and cocoanuts as its staples, but tin has been discovered and is now being worked profitably. The other States not in the Federation came under British suzerainty in 1909. Here substantial progress is also being made under the guidance of the British Advisers, and the general outlook is such that one is safe to predict that the Malay Peninsula, provided it can obtain a plentiful supply of labour, will take the foremost place amongst the tropical possessions of Great Britain.

RESOURCES OF FINLAND.

The following information regarding the resources of Finland is given by a correspondent in the *Times Trade Supplement*:—

The export trade of Finland comprises principally timber, chiefly in the shape of sawn goods, but also pitprops, etc. Sales of sawn goods in 1913 reached 625,000 standards (at 165 English cubic feet), of which 550,000 standards were shipped. At the beginning of 1919 stocks amounted to 1,100,000 standards, of which 580,000 standards were shipped during that year.

In 1920 there was, therefore, a balance of 520,000 standards. As the production during the year is estimated at 3-400,000 standards it is hoped that 8-900,000 standards will be shipped. The export of bobbins is also considerable.

The second place in Finland's exports is taken by the products of the paper industry. These comprise:—

		Tons.
Mechanical pulp and boards . .	about	150,000
Chemical pulp	,,	250,000
Paper	,,	200,000

In connection with the timber industry the production of three-ply wood may be mentioned. This is constantly increasing, but the production of ready-made doors, windows, and houses has so far not yet reached high figures.

The match industry in Finland is old established, its products having been sent to Western Europe, the Mediterranean countries, and, in exceptional cases, to the ports on the Black Sea.

Dairy produce has taken a prominent place in export trade. Considerable quantities of butter used to be sent to the United Kingdom, and of butter, milk, and cheese to Russia. The export of butter will hardly reach a high level during the near future, owing to increased home consumption through higher standard of living. On account of the difficulty of importing sufficient quantities of cattle food, butter production is hampered. Butter shipments to the United Kingdom have already taken place this year, and will be possible again after Finland's own demand has been satisfied.

The export of live stock, which in previous years was considerable, particularly to Sweden, is at present insignificant; but a fairly important trade in wild fowl and furs has sprung up. Hides,

particularly calf hides, have been exported during the past few years.

Quite an important development has taken place in the wood distillation industry. Owing to the application of modern technical methods, the export of tar and turpentine is beginning to show good results.

Amongst articles of export should also be mentioned granite, cut or uncut, and in the near future window glass.

OPENING UP WESTERN CHINA.

The increasing traffic on the Upper Yangtse is commented on by the Shanghai special correspondent of the *Times Trade Supplement*. For the first time an American trading firm is now entering the trade of Szechuen.

The Standard Oil Company had its own steamers running between Ichang and Chungking, but no American firm engaged in general trade has seen fit to engage in business in this part of the world.

Now, however, a United States concern has purchased one of the Standard Oil Company's vessels, and has adapted this to carry general cargo. This friendly competition will do much to develop the vast resources of Szechuen. In addition, a trading concern in Hankow, has placed an order for a special type of steamer for this service with a firm on the Clyde, on behalf of Chinese purchasers. Negotiations are in progress with the representatives of other United Kingdom shipbuilding firms for two more steamers, all for Chinese interests.

The ordering of steamers for the Upper Yangtse trade by Chinese is a very good illustration of the readiness with which they will adopt machinery and modern methods when it is actually demonstrated to them that these possess advantages over their own time-honoured methods. For centuries all traffic through the Yangtse gorges was by junk, laboriously towed up by man-power. It is estimated that the loss of cargo, through the junks being wrecked on the rocks in the gorges, in the last season was 60 per cent., whereas only one accident occurred to a steamer, and that through sheer incompetence. With such an object lesson before them, the Chinese are hastening to obtain steamers for the service. So far, British design and principles have been adopted.

The opening up of these hitherto undeveloped territories will mean a big demand for modern machinery and appliances, but, above all, for small power units. Oil and suction gas-engines especially will be wanted, and those interested in the manufacture of these should lose no time in conducting a properly organised campaign to demonstrate their uses. It is seldom realised how readily the Chinese adapt themselves to the use of modern machinery, and they are beginning to see the advantages of small power plants which they can install in their homes. It is not only in remote areas that this demand for machinery is growing. Where electric power is available a demand exists for small motors, and this branch of the machinery business has not yet been thoroughly exploited. For instance, there are thousands of looms worked by man-power all round Shanghai in native homes which use electric light. It is not a big step from electric light to electric power, but the advantages want systematic demonstration. With regard to the provision of funds for Shanghai's electricity extensions, a gold loan was sanctioned, and this has now been issued. It is a sterling loan, which should be popular, and the Council ought to have no difficulty in raising all the money it needs.

It is difficult to realise how enormous the field for machinery and engineering plant is in China until figures are studied. Recently an opportunity occurred of seeing what a leading British firm was doing in the machinery and engineering market. Before the war the total staff of its engineering department consisted of about six persons. The staff of that department to-day consists of more than forty men, and that number is to be doubled, orders having been telegraphed to their London office to engage a number of men immediately. The offices occupied by the engineering department of this particular firm cover a space at least four times greater than before the war, and further extensions have had to be arranged.

THE SOUTH AFRICAN FRUIT INDUSTRY.

The production of citrus fruits in South Africa was in the past confined to comparatively small areas, and the annual income derived therefrom a matter of small moment. There was no inducement to plant large numbers of orange and lemon trees, because the total white population of the country was small and the demand limited. As soon as it was demonstrated that oranges could be successfully exported to the European markets the matter assumed another aspect, and it was gradually realised that here was a business which could be exploited to an almost unlimited extent.

Just as South African deciduous fruits arrive in Europe at that season of the year when the market there is bare and there is no competition, so do the citrus fruits arrive when the supply from Europe and North America has ceased, and South Africa has almost a monopoly of the orange business from June until October. This means that it is now possible to obtain in Europe South African citrus fruit of all kinds just at that period of the year when they are most appreciated and are most beneficial from a health point of view.

An interesting account of the progress of fruit-growing in the Union and the development of an export trade, with special reference to citrus and other non-deciduous fruits and to berries, recently appeared in an official publication issued in South Africa, and formed the subject of a report to his Government by the United States Consul at

Durban, from which the following extracts are taken:—

Oranges.—Oranges are grown principally in the Transvaal, Cape Province, and Natal. Very few groves exist in the "Orange" Free State, its name notwithstanding, and from a commercial point of view these are negligible. The area of land suitable for citrus fruit is more extensive in South Africa than that on which any other fruit will thrive, and for this reason it will be readily seen that the orange will be the leading export fruit within a few years. The suitability of vast tracts of land in the Transvaal and Cape Province to the growth of the orange is demonstrated in the thrifty appearance of an occasional tree planted where there happens to be a little water available.

The exportation of citrus fruit commenced in a small way in 1907, since which time considerable though not uninterrupted progress has been made. Each of the three producing Provinces is represented in the export figures. Very little difference occurs in the numbers shipped from the Transvaal and those from Cape Province. At one time the bulk of the citrus fruit exported from South Africa was grown in the Transvaal, then the Cape took a slight lead; now indications point to an increase in the Transvaal production.

Inspectors at ports and local shippers estimate the quantity of citrus fruits available for export in 1920 at:—

		Tons.
Cape Town, 200,000 cases . . .	equal to	11,111
Port Elizabeth, 40,000 cases . .	„	2,222
Durban	„	2,000
Mossel Bay, 10,000 cases . . .	„	555
East London, 3,000 cases . . .	„	166
	Total . .	16,054

The varieties of oranges for export have in the past consisted of the ordinary seedling of the country, with perhaps half a dozen of what may be termed "popular standard varieties." About 75 per cent. of the total have been seedlings. Future plantings, and consequently exports also, will undoubtedly, as has been the case in California, consist of standard kinds, and the favourites will be Washington Navel, Valencia Late, St. Michaels, Joppa, Jaffa, Mediterranean Sweet, and Malta Blood, in approximately the order named.

Naartjes, Grapefruit, Lemons, and Seville Oranges.—"Naartjes" in South Africa mean something like tangerines and mandarin oranges in any other country. At all events, the word "naartje" has become distinctively characteristic of the fruit, not only in South African markets, but in those of Europe. It is a pretty fruit, the popular varieties considerably smaller and flatter than an orange, and the flesh so beautifully divided into separate segments that a lady can eat a naartje without soiling a new pair of gloves. This is the reason why this fruit is called in the United States the "kid-glove orange."

The demand for grapefruit is larger in America than in any other country. As South Africa has not hitherto grown any to speak of, the Union has not been able to tap this most profitable market. The few hundred boxes that have been exported from South Africa have been sent to London, where the demand is also good and prices equally so for the right article.

As an export fruit, the lemon has not hitherto proved a success. This is attributable to the simple facts that in the first place over-sea prices are too low to appeal to South African growers, and, in the second, the supply of Mediterranean lemons is so large and the handling of the crop so economically done that there are few months out of the twelve during which the South African article has any opportunity of striking anything but a full market.

The Seville orange, known the world over as the Bitter Seville, is the one orange which is preferred for marmalade. No other kind makes such a beautifully clear product, and, although in California great efforts are being put forth to create a demand for marmalade made from the Washington Navel orange, the choicest marmalade is, and will continue to be, made from this fruit. The local demand for this fruit has been very small until the last few years, when a demand has arisen for better-class marmalade, with the result that the Seville was more in demand. Possibly there are not more than 5,000 Seville orange trees in South Africa to-day, and they are not worth planting to any extent, although good prices should be obtained for some years to come. The trouble is that the Spanish product is available in such huge quantities and at such low figures that prices are forced down below the limit which South African growers regard as profitable.

Berries and Bush Fruits (Olives).—Berries and bush fruits are conspicuous in South Africa by their absence, the only berry grown to even a moderate extent being the strawberry. This is produced in every Province of the Union. More prominence is given to it perhaps in the western part of Cape Province than in any other area. This is accounted for by the fact that there is a large demand there for strawberries for jam purposes, some of the largest factories in the Union being situated in that district. Near Johannesburg and other large towns strawberries are grown purely for local consumption, and the demand is still in excess of the supply. The English Laxton strains are favourite varieties, as are also Melba and British Queen.

The raspberry grows and flourishes in parts of the Transvaal, the eastern part of Cape Province, in Natal, and Basutoland. Little attention has been paid to its cultivation, and a valuable and exceedingly delicious fruit is practically unexploited.

The blackberry is to be found growing wild in many parts of the Union. In the western part of Cape Province it is most prolific, and has been in demand by the jam factories for many years. Little, if any, attention has been paid to the cultivated varieties.

The English gooseberry does not grow to perfection in any part of South Africa. The only places where it is to be found of even moderately good quality are on the high veld in the Transvaal and at some fairly high elevations in the eastern part of Cape Province.

"Cape" gooseberries make one of the most delicious preserves. They grow almost anywhere and with a minimum of attention; in fact, they are often regarded as weeds. As a cultivated crop they pay well and are worth about 3*d.* a pound (cleaned) at the jam factories. Not many are cultivated, but the demand is always present, and this berry should receive commercially a great deal more attention than it does. Growers should make sure of a market before embarking on the planting of large areas, though most of the jam factories are willing and anxious to enter into contracts for the supply of this fruit.

Wild olives are found through the length and breadth of the Union; they flourish in the Cape, Natal, and Transvaal. It is therefore assumed that cultivated varieties will thrive correspondingly; but so far all attempts to establish a successful olive industry in South Africa have failed.

Avocadoes, Mangoes, and Loquats.—The avocado, often wrongly termed the "avocado pear," rejoices in the appellation of "alligator pear" in the United States. The tree as known in South Africa needs a warm climate, and is recognised as being one that will not put up with low temperatures. The avocado is grown principally in Natal and the warmer parts of the Transvaal, and the fruit is one which has undoubtedly a future before it. It is particularly rich in oil, and is one of the most nutritious and wholesome to eat. Unfortunately the varieties grown in South Africa at present are not suitable for export.

Mangoes are grown to greater perfection in the Barbeton district of the Transvaal than in any other part of South Africa.. The culture of this fruit there is of comparatively recent origin, and the production of choice varieties entirely so. Natal also produces mangoes perhaps even in larger quantities than the Transvaal, but, owing to the fact that atmospheric conditions are too damp in the vicinity of the largest plantations, the same success has not been attained in the growth of the mango in that Province. Many of the best varieties from India and Ceylon are obtainable, and although the trees have not up to the present attained the magnificent size of those growing in the countries named, they are shaping extremely well, and with age will yet make trees of respectable size. The nomenclature of the different varieties has been sadly neglected, and local names have now been largely adopted; such, for instance, as the Peach, Sabre, Kidney, and Large Green. These names indicate to South African growers and consumers the variety alluded to, but afford no guaranty to the stranger seeking knowledge. A few mangoes were exported about 1908 and realised such attractive prices that a boom in mangoes at once became imminent. It was, however, staved off temporarily, thus affording time to decide on the particular types of mango to plant for export. These eventually proved to be the Peach, Sabre, and Large Green, the first-named leading on account of its size and handsome appearance and immunity from "blackspot," which is the one disease to which the fruit appears to be subject in South Africa.

The loquat is another handsome fruit tree, though it is grown for shade in South Africa even more than for the sake of the fruit it bears. Its large, dark-green, glossy leaves and spreading branches afford a delightful shade during the "hot spells" with which South Africa is not unfamiliar. As far as the loquat as a fruit is concerned there is little to be said in its favour. Prices obtained are not sufficiently attractive to induce large plantings, and the few fruits found on the local markets are those from the trees already mentioned.

Bananas and Pawpaws.—As an ornamental plant or desirable adjunct to the garden for the sake of its foliage the banana is found all over South Africa. In Natal alone does the commercial aspect come into evidence, and even there cultivation is not anything like as extensive as it might be. It is true that in parts of the country a few bunches of common plantain-like bananas are to be found, but no actual business worth mentioning exists outside Natal. The Natal banana (*Musa Cavendishii*) is the variety principally cultivated, although the Lady's Finger is also found scattered here and there throughout the Province. There has been some slight export trade to Portuguese and former German African territories, but the bulk of the fruit is sold within the Union. There is little likelihood of any development of an export business with Europe; the banana trade in that quarter is already well established with the West Indies and is in strong hands. Further, Natal can barely supply the Union's own requirements. There is an occasional brief display of interest over such products as banana flour and banana coffee, but Natal growers at any rate can afford, as long as moderately good prices are obtainable, to neglect side lines of this description. It appears unlikely at present that any development of an extensive nature will occur in the planting of bananas. The business is principally in the hands of Indians, and, no matter how desirable these may be as vendors and distributors of fruit, they do not make good fruit growers. The tendency displayed is to take all that it is possible to get out of the ground without making any corresponding return. Under these circumstances, then, no immediate development of the banana industry can be looked for, yet the quality of the Natal banana is equal to any that grows.

The pawpaw grows principally in Natal and the low veld of the Transvaal, and is one of the most acceptable of fruits. In order thoroughly to appreciate it one ought to live in a fairly hot part of the country, where its non-appearance at

breakfast or dessert always causes long faces. The tree grows readily from seed and bears fruit sometimes under twelve months from the date of planting. An average time before bearing is eighteen months. Pawpaws are sold largely in Johannesburg, which is really the principal market in South Africa, and to a lesser extent in the towns of Cape Province, where the fruit does not seem to be as well known as it deserves. It is an extremely profitable tree to grow, though there are few orchards of pawpaws. There is one instance, however, of a pawpaw farmer, who gives all his time to the production of this fruit and makes a good living out of it. Inquiries have been made recently with regard to the extensive cultivation of the pawpaw for the purpose of producing papain, which is the active principle of the fruit, and has been used both medicinally and for dental purposes. It is a moot point as to whether the papain can be produced at a price sufficiently low to compete with the same products as turned out in the West Indies and other countries where labour is more plentiful and less expensive than in South Africa. There is little doubt but that the pawpaw is among the most healthful of fruits to eat, and as an aid to digestion possesses remarkable properties. It is an old and true tale that to reduce tough steaks to tenderness it is only necessary to wrap the meat in leaves of the pawpaw.

Pineapples.—Pineapples, like most fruits of a more or less tropical character, thrive in Natal, the eastern part of Cape Province, and parts of the Transvaal. Natal was first in the field as a producer of pines, and has grown and exported them for a good many years past. The varieties grown most extensively are the Smooth Cavenne and Queen; the former is one of the largest and handsomest fruits South Africa has, but the latter, though far smaller (averaging perhaps 1½ lb. in weight), is, as a rule, of finer flavour. While these are and probably will remain the leading varieties under cultivation, there have been some five or six other kinds under trial at the Government experiment station at Winklespruit, Natal, though no outstanding success has so far been achieved.

The pine-growing area *par excellence* in South Africa is found between Grahamstown and Port Alfred, in the eastern part of Cape Province. Here may be found all that conduces to the production of pines of the finest quality. Sufficiently removed from the influence of the sea, this favoured area is still near enough to enjoy the moist atmosphere conducive to the raising of the best pineapples. More planting has taken place here than in any other part of South Africa, and, although the Queen pine was originally introduced to this district from Natal, that Province has been out-distanced as a producer. Recently the acquisition of the Langholm estates by the African Realty Trust has given an added impetus to the development of this industry. There are over 12,000,000 pines now planted on this tract, and land is being cleared and broken for the reception of still more.

Needless to say, the ordinary outlets are not expected to absorb the crops from this gigantic undertaking. As an aid to export, with which idea the plantations were originally started, an up-to-date cannery is now in course of completion at Port Elizabeth. We may therefore soon expect South African canned pines to figure largely on the menus of Europe. It has been stated that in 1920 the export of pineapples, principally of the Queen variety, will amount to 10,000 tons.

GENERAL NOTES.

Dairy Industry in Ontario.—In 1919 Ontario produced 31,900,000 lbs. of butter valued at 17,575,000 dols., 102,700,000 lbs. of cheese valued at 27,729,000 dols., milk and cream for the city trade, the ice-cream trade, and manufactured into butter on the farm 25 million dollars; and condenseries and milk powder factories ten million dollars, a total value of 80,274,000 dols. In his agricultural report for the last fiscal year the Dairy Commissioner for Saskatchewan shows the remarkable increase of 18·70 per cent. for the province in dairy production. Though ninety-seven cars of butter were reserved for home trade, a total of 2,425,000 lbs. of butter went to outside markets. The value of the dairy products is given as 3,180,622 dols.

Marl Deposits in Finland.—In Vasaholm, in Nogio, Finland, a deposit of mollusc marl has been discovered, writes the United States Consul at Helsingfors. The field is 1,630 ft. long, 130 ft. broad, and 20 ft. deep. It is estimated to contain 125,000 tons of usable marl. The chemical analysis shows calcium oxides and 80 per cent. carbonate of lime. The high percentage of lime renders the deposit important as a fertiliser.

Telephones in the United States.—According to a report issued by the Bureau of the Census showing the results of the census of telephones covering the year 1917, there are 53,234 separate telephone systems and lines. These lines and systems operated 28,827,188 miles of wire in the United States, and connected 11,716,520 telephones and 21,175 public exchanges. The messages or "talks" sent over these wires aggregated the stupendous total of nearly 22 billion, or, to be exact, 21,845,722,335. Figured on the estimated population of the country in 1917 this gives 211 messages per annum to every man, woman and child. The industry in 1917 gave employment to 262,629 persons, of whom 171,119, or over 65 per cent., were women. The sum paid out in salaries and wages amounted to 175,670,449 dols. These employees operated plants and equipment valued at 1,492,329,015 dols., which yielded operating and non-operating revenues of 391,499,531 dols.

NOTICE.

REPORT ON THE "OWEN JONES" PRIZE COMPETITION.

With the kind assistance of the Director of the Victoria and Albert Museum, the Council again arranged for a competition of students of Schools of Art in accordance with the terms of the Owen Jones Trust. Notices were issued in October last stating that six prizes would be offered under the usual conditions, each prize consisting of the Society's Bronze Medal, and a copy of a book or books on Applied Art, of a value not exceeding £2, to be selected by the successful competitors. In addition to these, a Special Prize of £20 was offered for the best design (irrespective of class) submitted. The subjects of the competition this year were:—

Domestic Pottery and Table Glass.

Metalwork: Including work in Precious Metals, Ironwork, Jewellery, Enamelling, etc.

Textiles*: Including Lace,† Embroideries,† Openwork,† Dress Brocades, Dress Designs and Costume Accessories (including Fans), Printed Fabrics for Dress.

The date for the receipt of competing designs was fixed for June 26th, 1920, and arrangements were made for their inspection at the Victoria and Albert Museums.

The following judges were appointed by the Council to consider the designs submitted: Mr. C. Harling Comyns, Mr. A. F. Kendrick (Department of Textiles, Victoria and Albert Museum), Mr. T. C. Moore, Mr. Harry J. Powell, Mr. Bernard Rackham (Department of Ceramics, Victoria and Albert Museum), Mr. John Slater, F.R.I.B.A., Mr. P. G. Trendell (Department of Textiles, Victoria and Albert Museum), Sir Frank Warner, K.B.E., Mr. W. W. Watts, F.S.A. (Department of Metalwork, Victoria and Albert Museum), and Mr. James Yeo (of Messrs. Debenham).

Ninety-four designs or works were submitted by sixty-three competitors from seventeen centres. These figures compare favourably with those of last year, when fifty designs were sent in from nine centres by thirty-one students, though they are still a good deal smaller than the totals for 1917, when one hundred and twenty designs were submitted by seventy-three students from twenty-two schools.

The centres represented were:—

Belfast (1); Bradford (1); Coalbrookdale (2); Hyde (1); Leeds (5); Leek (2); London: Camberwell (1), Ealing (3), Hammersmith (2), Hornsey (6), Putney (12), South Kensington (1); Liverpool (7); Macclesfield (9); Northampton (5); Watford (1); West Bromwich (4).

The designs submitted included:—

Embroidery (29), Printed Fabrics (22), Pottery (10), Woven Fabrics (16), Lace (9), Metal Work (7), Painted Material (1).

There were no entries for glass, and of the ten entries for pottery and seven entries for metal work the judges did not consider any worthy of a prize and only one (in pottery) worthy of commendation.

The awards of the judges are as follows:—

SPECIAL PRIZE OF £20 AND PRIZE.

Evelyn May Scott, City School of Art, Liverpool.
Embroidered Panel for Fire Screen with Drawing.

PRIZES.

Dennis Arnold, School of Art, Leeds.
Design for Printed Cotton Voile Dress Material.

Jean Dick, City School of Art, Liverpool.
Fan in Limerick Lace with Drawing.

Catherine M. Spencer, Art School, Ealing.
Design for Printed Voile.

George Smith, School of Art, Macclesfield.
Woven Silk Dress Brocade.

COMMENDED.

Muriel Jones, Hornsey School of Art.
Nos. 2 and 3 of Sheet of Four Designs for Machine-printed Dress Fabric.

* It should be particularly noted that only certain classes of textiles are eligible each year.

† Designs for Bed-spreads, Table Covers, Cushion Squares and Tea Cosies were eligible.

Jean Dick, City School of Art, Liverpool.
Night Dress Case in Canvas Stitch (two-sided Italian stitch, background only worked) and Drawing.

Hazel L. Montgomery, City School of Art, Liverpool.
Circular Embroidered Panel.

Thomas Johnson, School of Art, Macclesfield.
Woven Silk Dress Brocade.

Robert Morton, School of Art, Macclesfield.
Woven Silk Dress Brocade.

William Ray, School of Art, Macclesfield.
Design and Draft for Woven Silk Dress Brocade and Executed Material.

Fred. Wright, School of Art, Macclesfield.
Designs for Woven Silk Dress Brocades.

Herbert Woodman, School of Art, Macclesfield.
Design and Draft for Woven Silk Dress Brocade and Executed Material.

Ethel Birchenall, School of Art, Macclesfield.
Embroidered Cushion Square.

Marguerite Elizabeth Bayley, School of Art, Northampton.
Embroidered Bedspread.

Dorothy Livingstone, Putney School of Art.
Sheet (Half-set) of 58 Designs for Lace.

M. Holman, Putney School of Art.
Design for Printed Silk. (Commended for design only—colour not approved.)

William Frederick Godfrey, School of Art, Watford.
Design for a Plate.
Design for Printed Silk. (Design commended, but scale of pattern considered too small.)

L. Cole, Ryland Memorial School of Art, West Bromwich.
Embroidered Table Centre worked in fishbone, button-hole and chain stitches.

A. B. Woodhall, Ryland Memorial School of Art, West Bromwich.
Corner of Table Cloth in Cut Linen Embroidered.

Arrangements have been made for the exhibition to the public of the competing designs as in previous years. They are now and will remain on view until August 31st, from 10 a.m. to 6 p.m. (on Sundays from 2.30 to 5 p.m.) in the Class Room, Department of Textiles (First Floor), Victoria and Albert Museum, South Kensington, S.W.

In announcing the awards the Council desire to express their thanks to the judges for the trouble they have devoted to the work and for the promptitude with which the awards have been made.

They wish also to state their appreciation of the assistance rendered to the Society by the Director of the Victoria and Albert Museum and his staff.

The full conditions and arrangements for the Competition in 1921 will be announced later.

PROCEEDINGS OF THE SOCIETY.

JOINT MEETING OF THE INDIAN AND COLONIAL SECTIONS.

A joint meeting of the Indian and Colonial Sections was held on Friday, June 4th, 1920; The Right Hon. E. G. Pretyman, M.P., in the chair.

The Chairman, in introducing the reader of the paper, said that no one was more qualified to speak on the subject with which he proposed to deal than Sir John Cadman, who had been acting for some considerable time as the official adviser of the Government, being the principal permanent official in the Petroleum Executive which had recently been created.

The paper read was—

THE OIL RESOURCES OF THE BRITISH EMPIRE.

By Professor Sir John Cadman, K.C.M.G., D.Sc., F.G.S., M.Inst.C.E.

To endeavour to compress even a brief *résumé* of the Empire's oil resources into the space of time which is allotted to me is a task of such magnitude that I realise at the outset that when I have finished addressing you I shall have barely touched the fringe of the subject.

So much publicity is being given to the subject of petroleum at the present moment, that it is a little difficult to explain what it all means. On the one hand an effort is made to show that one group of capitalists is more worthy and better fitted than another to develop the petroleum which probably underlies certain parts of the hinterland of Mesopotamia; and on the other hand the present world's shortage of petrol introduces famine prices, which, it is suggested by some, should be corrected by price-limiting machinery—which would result in focussing this shortage more acutely on those who adopted such machinery.

As regards oil in Mesopotamia, it is not new; it has been known for many years that Mesopotamia offers possibilities for the prospector, and it has been open to all comers to try their 'prentice hands in extracting it. Again an outcry has arisen in the United States that Great Britain is attempting to collar the world's oil supply.

That country has not hitherto enjoyed a stable Government, and it is only now that it is suggested that it should come under the mandate of Great Britain, and the responsibility of keeping law and order is relegated to the charge of a responsible Government, that the

prospect of acquiring concessions in Mesopotamia has suddenly become so attractive.

The enormous growth in the use of petroleum and petroleum products, stimulated in no small degree by the war, has led to a demand which at the moment threatens seriously to outstep the supply. Production, paralysed during the war by lack of material for field development, has not kept pace with requirements, and in consequence there is a world shortage, with the natural result of famine prices and an abnormal eagerness to explore new and untried fields. It is these factors which have directed attention to new sources of supply, and which have prompted your committee to invite me to say something about the oil resources of our Empire.

In order to enable you to bring this problem into proper focus, I propose to picture to you in the first place what the world's resources of petroleum are, and from where they may be expected to come, both geographically and geologically; and then, if I can, to indicate to you which are the probable new sources of supply, and how far these new sources fall within the boundaries of the Empire.

It will be noted by reference to the map of the world that the continent of North America produces to-day about 85 per cent. of the world's output of crude oil. The United States at present produces in her own territory nearly 70 per cent. of the world's oil output, while if the quantity produced by United States companies in Mexico is added, the total United States control in North America is at least 80 per cent. of the world's oil supply. It will be seen, further, that the British Empire produces only about 2½ per cent. of the world's supply, or, if Persia may be said to be under British influence, about 4½ per cent. of the whole.

All this newspaper chatter as to the imminence of British domination in oil is shown to be absurd when this tremendous disparity is realised.

We have depended on the United States for oil supplies in the past, and we must continue to draw largely upon her in the future—and for the invaluable assistance which we have received from her every sane-thinking person cannot fail to feel profoundly grateful.

It is only too true that the United States is herself consuming ever-increasing quantities of oil, and that her available exportable surplus of oil is dwindling. It has been said that the United States reserves of oil are becoming rapidly exhausted, but it is difficult to accept the very pessimistic reports which have lately been made public. Oil is not a commodity that can be easily measured, and no estimates, however conservative, can be strictly relied upon. We have seen in this country a parallel in the alarming rumours which predicted the early exhaustion of our coal supplies, and we have repeatedly seen how far from the truth the alarmist figures are.

Nevertheless, it is true that the greatest producer of oil to-day is absorbing more and more of her own supply, and it behoves us to look round to see, in the most friendly way, from where are we going to be served when the United States finds it difficult to supply us, and we, too, are calling for more and more of this vital product.

It is most unfortunate that the Press of this country and the Press of the United States, should at this juncture be hurling wild statements about, many of which are most misleading and inaccurate. It has been stated that Great Britain is developing an oil policy which definitely excludes the foreigner from participating in and helping to develop any of the Empire's 2½ per cent. production to-day, and that she is deliberately shutting the door to foreign capitalists. To those statements which have appeared in the Press the following comments may be offered:—

1. Certain requirements as to British directorates and domicile are imposed on petroleum-producing companies in some parts of the British Empire, but there is no general ban on foreigners of the nature alleged. Even where such restrictions are in force American interests are to be found at work—*e.g.*, in Canada the Imperial Oil Company, a direct and very powerful subsidiary of the Standard Oil Company, occupies a commanding position, and in Trinidad an American company, the General Asphalt Company of Philadelphia, controls one of the principal operating companies. While foreigners are excluded from India, there are no restrictive measures in Australia, New Zealand, South Africa, or Egypt.

2. It has been suggested that it is our settled policy to prohibit the sale of British oil companies to foreign interests, and even the transfer of shares in British oil companies to aliens. Any regulations of this kind were war measures of a perfectly natural and legitimate kind, and it is quite inaccurate and misleading to refer to them as part of the permanent policy of His Majesty's Government, and as indicating a determination to exclude foreigners from participation in British oil enterprises.

Again, in regard to Persia, the suggestion that Americans are under any special disability in that country is absolutely incorrect. As the Anglo-Persian Oil Company hold the concession other British and foreign interests are naturally excluded, but there is no truth in the statement that the Anglo-Persian Oil Company's rights have been in any way strengthened by the Anglo-Persian Agreement of 1918. The concession was acquired in 1901 through the individual enterprise of Mr. W. K. D'Arcy, and it was equally open to Americans or any other nationals to secure it.

As regards occupied areas, it has, as stated, been the policy of His Majesty's Government to prevent prospecting for minerals by British or foreign companies until the future administration of these territories is settled. When this has been done, rights claimed by American and other nationals will presumably be considered. The restrictions imposed have been considered essential to prevent confusion and friction.

The Oil and Coal Leasing Act, lately passed in the United States, contains a reciprocity clause providing that, if any country places restrictions on United States citizens in regard to the working of coal or oil, the nationals of that country should be excluded from any participation in the working of lands covered by the Act.

It is interesting to note that Mr. A. C. Bedford, of the Standard Oil Company, says that what is needed is an agressive foreign policy on the part of the United States Government; while Senator Phelan proposes the formation of a United States Oil Corporation to stimulate the development of foreign oilfields by Americans. As to this, it need only be said that in the past Americans have prospected or found oil in Roumania, Palestine, China, the Dutch Indies, Canada, Mexico, Costa Rica, Colombia, Peru, Cuba, Trinidad, and elsewhere. Any oil concessions which British subjects hold abroad have been acquired purely by individual enterprise, and they enjoyed no special advantage in the way of Government backing, nor did they wait to secure Government encouragement and support.

On this difficult question I can only say that Great Britain is too sensible of what she owes to those who have kept her so well supplied in the past, to adopt any attitude other than that of strict impartiality and fairness.

Having made these preliminary remarks upon certain aspects of the oil situation which are attracting attention to-day, I would ask you to consider under what conditions petroleum exists, and in what quantity may it be expected to occur within those conditions.

Liquid oils may be divided into two groups:—

1. Those which occur in Nature as crude liquids.

2. Those which can be obtained by distillation from shales and coals.

It is to the former group that I must direct attention this afternoon, although much of our future supply will probably be received from the latter group.

It is an interesting geological fact that the conditions which favour the deposition of natural petroleum seem to be associated with two definite geological horizons—viz., the Tertiary and the Carboniferous—and it was during this period that vegetation thrived on this planet.

The following table illustrates this point more precisely:—

THE GEOLOGICAL DISTRIBUTION OF OIL IN THE CHIEF OILFIELDS ARE AS FOLLOWS:—

Geological Formation.	Percentage Production.	Locality.
Tertiary	49·4	California, Gulf Coast, Mexico, and most of the British Colonies.
Upper Cretaceous	1·0	Texas, Wyoming, Colorado.
Lower "		
Jurassic		
Triassic		
Permian		
Carboniferous, Upper Devonian	41·1	England, Texas, Oklahoma, Kansas, Pennsylvania, Illinois, and the Appalachian field.
Devonian	0·4	Canada.
Silurian		
Ordovician	8·1	Lima-Indiana.
Cambrian		

I now propose to show very approximately how far these rocks are disseminated over the surface of the planet, and how relatively little has yet been done in prospecting for petroleum within this vast tract of land. I have indicated on the map of the world where these deposits lie, and you will see then how far they penetrate within the confines of the British Empire.

Out of approximately 60 per cent. of the globe's surface covered by these rocks, only an infinitesimal part has yet been thoroughly examined for petroleum products, and it must be some comfort to imagine that even if only a moiety of them are found to contain petroleum, the stores of petroleum in the world are still plentiful and only await discovery by the geological hammer and the drill.

The figures for production and consumption for 1918 were as under:—

	Production, 1918 Tons.	Consumption Tons.
United Kingdom	250,000	5,395,000
Canada	40,000	1,717,000
Trinidad	300,000	112,000
India	1,150,000	1,292,000
Egypt	250,000	424,000
Australia } New Zealand }	10,000	110,000
		67,000
Sarawak	80,000	—
Total British Empire	2,080,000	9,117,000
Persia	1,500,000	
World's Production	70,000,000	

The consumption and production of petroleum products in the British Empire has been approximately:—

	Consumption.	Production.
1912	4,212,000	1,421,000
1913	4,713,000	1,519,000
1914	5,467,000	1.563,000
1915	5,184,000	1,629,000
1916	6,128,000	1,655,000
1917	7,485,000	1,774,000
1918	9,117,000	2,080,000

The figures in the table below show approximately the present consumption and source of supply for the United Kingdom, although in 1918 the consumption was on the basis of $5\frac{1}{2}$ million tons per annum.

It may be interesting to review briefly the present position of the oil supplies of each zone within the Empire which is at present attracting attention.

Great Britain.

The United Kingdom is at present a comparatively small oil producer, practically all its requirements being drawn from overseas. Until quite recently (May, 1919) production was confined to the shale deposits of Scotland, which stretch from the Forth, between Dalmeny and Blackness, southwards to Tarbrax.

These oil-bearing strata produce about 3,250,000 tons of shale annually, the average yield being from nineteen to twenty gallons per ton of shale, or approximately 250,000 tons of crude oil. The output during the last eight years has been as follows:—

	Output of Oil Shale. Tons.	Crude Oil Produced. Tons.
1911	3,206,756	293,660
1912	3,284,956	294,699
1913	3,369,321	289,684
1914	3,388,869	285,464
1915	3,187,592	263,083
1916	3,102,036	247,472
1917	3,200,883	249,598
1918	3,223,076	242,501
1919	2,814,110	211,986

Deposits of shale have also been known for many years to exist along an irregular line stretching from Kimmeridge in Dorsetshire to King's Lynn in Norfolk, and on as far as Yorkshire. None of these deposits are being worked with the exception of the Norfolk area, which English Oilfields, Limited, are attempting to develop. Several seams are stated to have been proved, and the Company expect to be working on a commercial scale at an early date; but progress in development of a new shale field must necessarily be slow.

Imports of all Petroleum Products to the United Kingdom.		Consumption in the United Kingdom.	
Origin.	Quantity (Tons).	Products.	Quantity (Tons).
United States of America	1,800,000	Crude Oil	30,000
Mexico	500,000	Kerosene	620,000
Dutch East Indies	120,000	M.T. Spirit	650,000
British India	60,000	Lubricating Oil	260,000
British West India Islands	130,000	Gas Oil	120,000
Persia	90,000	Fuel Oil	1,020,000
Total	2,700,000	Total	2,700,000

Occurrences of natural petroleum have, from time to time, been reported from various points of the country, and in 1914 a systematic geological examination was begun by Messrs. S. Pearson & Son, and in October, 1918, they commenced drilling operations as agents of His Majesty's Government. A series of bore-holes were put down in the Chesterfield area, and in May, 1919, the Hardstoft boring struck oil, and flowed with a daily production of about ten or eleven barrels of oil, and it has since been steadily producing at this rate.

Tests are also in progress in North Staffordshire (Apedale and Werrington), and in Scotland (West Calder and D'Arcy), while at Kelham, near Newark, a well is being sunk by Oilfields of England, Limited.

An analysis of the Hardstoft oil is as follows:—

Motor Spirit	7·5	per cent.
Kerosene	39	"
Gas Oil	20	"
Lubricating Oil	30·5	"
Paraffin Wax	3	"
Sulphur	0·26	"
Sp. gr.	·823	

Calorific value 20,290 B.T.U.

Some idea of the requirements of the United Kingdom for petroleum products can be gauged from the following table:—

Year.	Production.	Imports.	Expressed in Tons. Totals.	Exports.	Difference (Consumption).
1912	294,699	1,653,333	1,948,032	26,846	1,921,186
1913	289,684	1,962,427	2,242,111	16,505	2,225,606
1914	285,464	2,586,850	2,872,314	20,444	2,851,870
1915	263,083	2,354,079	2,617,162	46,079	2,571,083
1916	247,472	3,159,195	3,406,667	27,907	3,378,760
1917	249,598	4,187,569	4,437,167	20,800	4,416,367
1918	242,501	5,166,218	5,408,719	6,996	5,401,723
1919	211,986	2,749,652	2,961,638	112,811	2,848,827

Cyprus.—Indications of petroleum in Cyprus seem to be confined to the dark-oil-bearing phase of a crystalline limestone, probably of Cretaceous age, occurring in the northern mountain range, but the physical character of this rock and the structure appear to be unfavourable for the accumulation of oil on a commercial scale. Four wells have been sunk without success, but, owing to the war, operations were suspended.

Malta.—There are rocks of suitable age and structure, and it is probable that test drilling will be undertaken.

Asia.

Persia.—The oilfields of Persia extend in a south-easterly direction along the western and southern sides of the Persian plateau adjoining Mesopotamia, the Persian Gulf, and Gulf of Oman, cross the Turco-Persian frontier between the Diyaleh (or Sirvan) river and Mendeli, and enter the Persian province of Kermanshah. Thence they run south-east through the provinces of Luristan, Arabistan, and the Bakhtiari country forming the northern area, and Behbehan Fars and Laristan forming the southern area.

It is uncertain how far the northern area extends to the north-east, but in the south-west numerous seepages are found in the gypsum and sandstone ridges forming the foothills of the south-west ranges of the plateau. The most important deposits have so far been found in the Bakhtiari country at Maidan-i-Naftun, about 140 miles north-east of Mohammera. The Naft Khana field on the frontier, about 16 miles north of Mendeli, has many surface indications. Luristan is believed to contain considerable deposits, and oil has been found at Kuh Dalpassi, about 120 miles north-west of Ahwaz, the general structure of the country being similar to that of the petroliferous regions to the north and south.

The southern area, in which practically little or no development has taken place, consists of a long belt of territory of unknown width extending along the coast from the head of the Persian Gulf to the Straits of Hormuz and Persian Makra, and may be divided into:—

(1) Scattered localities, known to be petroliferous, on the Persian littoral (with which may be included the island of Qishm, in the Straits of Hormuz) or within easy reach of the Persian Gulf.

(2) The mountainous hinterland forming the southern part of the Persian plateau, consisting

largely of wild and unexplored regions of the provinces of Fars and Laristan.

In 1901, Mr. W. K. D'Arcy obtained a concession from the Persian Government covering the whole of Persia except the provinces of Azerbaijan, Ghilan, Mazendaran, Asdrabad and Khorasan bordering on the Caspian Sea. The area of the concession is approximately 500,000 square miles, but only a few square miles have actually been worked, principally at Maidan-i-Naftun, where 3½ square miles have been proved and a substantial production is obtained. Oil in commercial quantities was, however, proved by the drill in the early days of the concession at Chiah Sourkh, north-east of Khanikin.

From Maidan-i-Naftun the oil is conveyed about 145 miles by two pipe-lines to the refinery situated on the Island of Abadan.

The output has increased from less than 100,000 tons in 1912 to about 1,000,000 tons in 1918.

The oil is of high quality, containing a large percentage of benzine, good kerosene and lubricating oils, fuel oil of unusually high thermal efficiency, and a good percentage of paraffin wax.

An analysis gave the following result:—

Specific gravity	0·840
Initial boiling point	48° C.
Distillation below 100° C.	11·0 per cent.
Distillation between 100° and 150° C.	12·3 „ „
Distillation between 150° and 280° C.	29·6 „ „
Residue	45·6 „ „

Mesopotamia.—The existence of petroleum and asphalt in Mesopotamia has been known since very early times. The oilfield in this country is only part of a petroliferous area which extends through Southern Persia to the north end of the Persian Gulf, passes through Mendeli on the Turco-Persian frontier, and crosses the Tigris near El-Fatha. The oil line follows the river to Mosul, and continues with interruptions to Zakho and the neighbourhood of Van following the Bothan river. This belt is approximately 1,000 miles long, and covers an area of more than 26,000 square miles.

Three main oil lines may be distinguished: the southernmost, on the Djebel-Hamrin, which starts at the oil wells of Mendeli and passes over El-Fatha to El Hadr; the second, which connects Kifri with Tushurmatu; and the third connecting Kerkuk with Garadagh. If the latter is continued in its north-westerly direction it leads directly to the petroleum wells of Tel Kyara. The existence of an oil line may also be assumed between the asphalt deposits near Hit, Nephata and Ramadi, and the oil deposits of Basra and Koweit. There are also numerous indications on the islands of the Persian Gulf.

Near Mendeli there are thirty pits, none of which are more than about 8 metres deep. The oil, which is dark and thick, gives on distillation about 30 per cent. kerosene, the residue being used as fuel. About 300 tons of crude oil are refined annually in this district. In the Tushurmatu district the yield of crude oil is about 700 tons per annum. In the neighbourhood of Kerkuk, over an area of about 37 acres there are about twenty springs giving an annual yield of approximately 300 tons of crude oil. The largest production is at present obtained from an area of about 246 acres near Tel Kyara, the annual production being about 1,500 tons. Near Zakho there are numerous seepages over an area of about 120 acres which give a yield of from 250 to 300 tons per annum. Along the Euphrates river the asphalt deposits of Hit and Ramadi have been known from ancient times, the yield of asphalt from the wells near Hit being estimated at about 2,500 tons per annum.

India.

Oil has been found to a small extent in the Punjab, in the Rawalpindi, Attock and other districts, but the main petroleum region of India is in the east—Burma, Assam, and the islands off the Arakan coast.

In Burma the oil producing area, which runs north and south, lies along the basins of the Irrawaddy and Chindwin rivers. Of the 400 miles along which indications exist, only about 90 miles have been found sufficiently profitable for development, the chief fields being Yenangyaung (Magwe District), Singu (Myingyan District), and Yenangyat (Pakokku District). The Yenangyaung field is the most important, its chief districts being Twingon and Beme. All these fields are connected by pipe-lines, which continue to the refineries at Rangoon. Other areas are Chindwin, Shwebo, Minbu, Thayetmyo, Prome, Henzada, Sittang Valley, and the Arakan region comprising Ramri Island and other small islands. The work in these districts has, however, been principally of an exploratory nature.

The oil has a specific gravity varying from ·800 to ·950. It is rich in kerosene, of which large quantities are consumed in India, and

also gives a valuable lubricating oil. The following is an average analysis :—

	Per cent.
Spirit	15
Kerosene	55-60
Solid Paraffin	12-14
Lubricating Oils	8-12
Loss and Coke	5

In Assam the principal fields are about sixty miles from the Thibet border, at Digboi and Makum. The bulk of the oil comes from the Digboi field, extensions of which have been proved at Bappapoong and Hansopoong. The oil is of paraffin base with a specific gravity at 60° C. of ·855 to ·860. An analysis is as follows :—

	Per cent.
Benzine	8·8
Kerosene	37·8
Lubricating Oils	49·4
Coke	3·8

There is a refinery at Digboi with a capacity of about 24,000 tons per annum, and tank storage has been provided both at the refinery and at the wells.

The total annual production of oil in India since 1908 has been as follows :—

Year.	Burma. Tons.	Assam. Tons.	Punjab. Tons.	Total Tons.
1908	693,611	12,972	2	706,585
1909	921,586	13,123	3	934,712
1910	846,031	13,283	4	859,318
1911	888,902	14,261	6	903,169
1912	981,341	14,990	4	996,335
1913	1,089,062	18,754	5	1,107,821
1914	1,018,612	18,754	5	1,037,371
1915	1,129,168	18,200	1,005	1,148,373
1916	1,167,076	20,948	735	1,188,759
1917	1,091,181	37,379	2,478	1,131,038
1918	—	—	—	1,146,340

The imports of all kinds of oil into India during the past four years have been as follows :—

		Tons.
1916		372,734
1917		288,749
1918		230,495
1919	(nine months)	321,760

The falling off in 1917 and 1918 was due to the scarcity of tonnage.

Africa.

Egypt.—The Egyptian oil region lies between 27° 10′ and 28° 10′ latitude north and 33° to 35° 50′ longitude east, with outlying districts on the western and south-eastern borders of Sinai; it runs parallel to the Gulf of Suez, and covers a width of from five to twenty kilometres. If the desert plain be included the area of the region is approximately 8,000 square kilometres, extending from Ismailia to Ras Buras, with a maximum breadth of fifty kilometres.

Gemsah was the main producing area up to 1914, but since that date its output has declined considerably, and commercial production is now confined to the Hurghada field, which is worked by the Anglo-Egyptian Oilfields, Limited, whose concession also includes the Gemsah field referred to.

The total production of these two fields since 1910 has been as follows :—

	Tons.
1911	2,793
1912	27,962
1913	12,618
1914	103,605
1915	34,961
1916	54,800
1917	134,700
1918	272,494
1919	232,148

Other districts where prospecting is being carried out are the west side of Gabal Zeit, Jaffatine Island, Ras Bahar (north of Gemsah), Gaysoon Island, Ras Dhib, Jubal Island, Ranim Island, and at Abu Zenina.

Storage tanks have been erected at Gemsah, Hurghada, and Suez, with a capacity of about 100,000 tons, and at the last-named place there is a refinery capable of treating about 1,000 tons of crude oil per day. Pipe-lines have been laid to deep water at three shipping berths at Port Tewfik.

The crude oil varies in quality, but that found at Hurghada is a heavy oil with a paraffin base.

Typical analyses are :—

Gemsah.—

Specific Gravity	·830 at 62° F.
Benzine (below 150° C.)	23 per cent.
Kerosene (150°–290° C.)	34 „
Fuel Oil (above 290° C.)	43 „

Hurghada.—

Specific Gravity	·928 at 62° F.
Benzine (below 150° C.)	10 per cent.
Kerosene (150°–290° C.)	14 „
Fuel Oil (above 290° C.)	76 „

Gold Coast.—Petroliferous lands are reported near the coast, in the neighbourhood of Appolonia and Birridaim. Wells have been sunk which prove the existence of various oil horizons, but no commercial quantities have so far been found.

Nigeria.—Indications of petroleum are found in Southern Nigeria, the surface formation consisting of sands of the Tertiary series underlaid by impervious shales, beneath which occurs hard limestone in which no traces of oil have so far been met with. With the assistance of the Nigerian Government drillings were commenced in 1905 in the neighbourhood

of the Oni River, Southern Nigeria. Six wells were sunk, but owing to difficulties in shutting off water the operations were abandoned.

Somaliland.—Geological expedition undertaken by Mr. H. T. Burls, confirmed at a later date by Mr. Beeby Thompson and Dr. Ball, revealed the existence in the Daga Shabell area, near Berbera, of a small field of asphaltic oil, rich in benzine, and apparently free from sulphur. A suitable series of sediments, presenting all the usual essentials of oilfields, is located over an area of many square miles, and oil-impregnated sands are found throughout a vertical thickness of 800 ft. in the lowest exposed beds of the series. The bituminous sands are reported to be progressively rich in oil as the lowest strata are approached. The oil is said to be of high grade, light density and sweet smelling quality.

A practical test of the field is to be carried out.

South Africa.—In 1913 it was reported that geological formations, favourable to the existence of oil deposits, were only to be found in a narrow strip at the southern edge of the Karroo, Cape Colony. The most important indications are those on De Drift and Oudeberg farms, in the Laingsburg Division, about twenty-nine miles north-west of Prince Albert Road Station, and on Ongeluksfontein, Tweefontein, and Varschefontein farms, some miles to the north in the Beaufort West Division.

In the district immediately surrounding Port Elizabeth the geological formation is said to be similar to that of the Caucasus belt, and it has been proposed to sink a test well about twenty miles from the town.

Oil-bearing shales have been opened up in various districts of the Union, but no payable deposit has yet been proved. The deposits in the Wakkerstroom field, Transvaal, showed on analysis an average yield of from 18 to 28 gallons of crude oil per ton of shale.

Beds of shale rich in oil are reported in Natal, and mineral oil is believed to exist near Harrismith in the east.

America.

Canada.—The areas where oil indications are met with in Canada are very numerous, but no serious effort has so far been made to develop them.

Natural petroleum occurs in Ontario, New Brunswick, Alberta, British Columbia, Newfoundland, and Athabasca, but the only area where regular production has so far been obtained is Ontario, of which the principal districts are Mosa, Oil Springs, Petrolia, Bothwell, Tilbury, Moore Township, Sarnia, Dutton, Thamesville, Plympton, and Onondaga. Recently, however, a gusher was brought in in New Brunswick having an initial flow of 10,000 barrels a day.

The total production since 1912 has been as follows:—

	Tons.
1912	34,762
1913	32,583
1914	30,686
1915	30,781
1916	28,303
1917	30,547
1918	43,534
1919	31,430

In Alberta indications of petroleum over large areas have attracted much interest, and considerable activity in development work is anticipated. Actual production, whilst not of much importance, shows that progress is being made, the figure for 1918 being about 1,863 tons compared with about 1,214 tons for 1917. Investigations along the Athabasca river show that the "tar sands," of which many millions of tons are available, are outcrops of sandstones impregnated with bitumen.

With regard to British Columbia, owing to the disturbed geological conditions, opinions differ as to the extent of natural oil deposits, of which there are occurrences on the coast. Oil shale deposits of considerable extent also exist.

Newfoundland.—Large deposits of bituminous shale, covering an area of about 150 square miles, are reported to exist near the west coast of Newfoundland, while similar deposits have also been traced at Deer Lake for a distance of 30 miles.

Traces of petroleum have been found on the shores of Parson's Pond, a stretch of salt water in bay formation, lying between St. Paul's Bay and Portland Creek on the north-west coast, facing the Gulf of St. Lawrence; attempts at development have not proved a commercial success, but they have recently been resumed.

Barbados.—Oil indications in the Scotland district, on the eastern side of the island of Barbados, have been found in the Tertiary strata, which is to some extent faulted and covered with coral limestone. In some places the coral beds are largely mixed with the debris of underlying strata, forming beaches, which not infrequently conceal important geological structures and render the following out of pre-coral flexures very difficult.

A small production of an asphaltic base oil was at one time obtained.

Trinidad.—Petroleum indications in Trinidad are practically confined to the southern part of the island along several more or less clearly defined parallel anticlines running from east to west, and all land south of latitude 10° 26′ 36″ N. has been officially declared oil bearing. The principal producing area is the Forest Reserve, near Brighton. Other districts are Mayaro, Guayaguayare, Tabaquite, and La Brea. There are three tenures of land: (1) Crown land, on which oil is the property of the Crown; (2) private land, where oil is also the property of the Crown; and (3) private land, where oil is the property of the landowner. During 1918, 47,487 ft. were drilled on Crown lands as against 6,751 ft. on private lands, the number of new wells drilled being thirty-seven on Crown and four on private lands, bringing the total number of wells drilled in the Colony to December 31st, 1918, to 410, of which 236 are on Crown lands.

Numerous oil gushers have from time to time been obtained principally from the upper horizon, production from the lower horizon being impeded by shifting sand, which tends to crumple up the casing and choke the bore-holes. It is hoped, however, that an effective remedy will be found for this difficulty.

Most of the oil has an asphalt base, that from the lower sands being much lighter than that produced from the shallow sands. At Tabaquite, an oil of paraffin base containing about 80 per cent. benzine is found.

The production in Trinidad since 1911 has been as follows:—

	Tons.
1911	17,516
1912	39,943
1913	70,506
1914	90,092
1915	147,015
1916	129,903
1917	224,324
1918	291,489

The largest and most important company is Trinidad Leaseholds, Ltd., which in 1918 had a production of 154,179 tons, *i.e.*, more than 50 per cent. of the total output for the colony. The United British Oilfields of Trinidad, Ltd., comes next with a production in 1918 of 88,054 tons; and other important companies are the Trinidad Lake Petroleum Company, Ltd., and the Petroleum Development Company, Ltd., with productions in 1918 of 18,282 tons and 16,478 tons respectively.

Pipe-lines run from the fields to the ports of shipment—Brighton, Point à Pierre, and Point Fortin.

Exports since 1912 have been as follows:—

	Tons.
1912	17,183
1913	54,618
1914	49,299
1915	57,742
1916	136,000
1917	148,000
1918	182,757

British Guiana.—There have been frequent reports of the existence of petroleum deposits in British Guiana, particularly in the north-west, in the region of the Waini river. Several exploration licences have been granted, but so far as is known no results have been obtained. A detailed geological survey of the area is being carried out.

British Honduras.—Honduras is reported to afford numerous and extensive indications of petroleum on the Caribbean coast line, the most noticeable being at Guare, sixty-six miles south of Puerto Cortez.

AUSTRALASIA.

British North Borneo.—Prospecting licences over 150 square miles in the Belait district of the State of Brunei, and over an exclusive concession comprising the whole of British North Borneo have been granted, and exploratory work is in progress. An area of 440 square miles on the Klias peninsula on the west coast, and the island of Mangalum, is held by the Kuhara Mining Company of Japan. The Kuhara Company are said to have received encouraging reports of a geological examination of the Kudat district, on the north-west coast.

Papua.—In British New Guinea evidences of petroleum occur along a coastal belt some eight to twelve miles wide, from the delta of the Purari river almost to Yule Island, surface indications being dotted over an area of about 1,500 square miles. The principal districts are in the Vailala area—Upoia, Orevi, Aro-Aro, Hohoro and Ekoa, Haiari and Vaiviri, Kiri and Pope. There are two main folds running north-south and east-west, a feature being the existence of small anticlines, which it is thought may merge at depth into single and larger anticlines.

Several wells have been sunk to prove the field, and fair shows of oil have been obtained. Owing, however, to difficulties with the strata, which largely consist of soft mud under considerable pressure, no commercial success has yet been attained.

In 1919 the British and Australian Govern-

ments agreed to co-operate in further examination of this territory.

In late German New Guinea oil indications exist between Eitape and Beaken Bay, the principal being near Amuloi, on a tributary of the Halikemak river, which enters the sea east of Smein village, sixty miles from Eitape and near the village of Matapau, about two miles from the mouth of the Wakip or Tiain river, which enters the sea about forty miles east of Eitape.

A rough survey of this area has shown the principal formations to be alluvial deposits of gravel, sand, and clay, outcrops of hard, slatey clay, and sandstone varying from fine-grained and hard to coarser, running into grits, conglomerates, breccias, and limestone.

The indications near Matapau are the most important, excavations showing the whole surface, sand, and gravels, to be heavily saturated with oil, which appears to be of paraffin base. It is dark brown in colour, a good rust solvent and lubricant, and burns with a reddish flame.

Australia.—Important oil shale deposits exist in Australia, but although efforts have from time to time been made to locate deposits of natural petroleum, no success has yet been attained.

In New South Wales a "kerosene" shale has been found at various geological horizons near Murrurundi, about seventy-five miles north-west of Newcastle, and also near Capertee, about 100 miles north-west of Sydney, on the railway to Mudgee. The yield of picked samples is sometimes as high as 130 gallons per ton of shale, but the average is about 80 gallons per ton. Over 12,000 acres, which are estimated to contain more than 20,000,000 tons of oil shale, have been proved.

An analysis of the oil gave the following results:—

Specific Gravity	1·104
Gasoline	7 per cent.
Kerosene	45 „
Gas Oil	25 „
Residuals	9 „

Commercial production commenced in 1868, when about 17,000 tons of shale were raised. More recent production has been as follows:—

	Tons.
1911	75,104
1912	86,018
1913	16,985
1914	50,049
1915	15,474
1916	17,425
1917	31,661
1918	32,395
1919	10,000 (Estd.)

The Commonwealth Oil Corporation, Ltd., which is the company most largely interested, has been considerably handicapped in its operations, owing to the difficulty of access to its properties and the lack of up-to-date methods of working. This latter deficiency is about to be remedied. The high wages demanded have in recent years also militated against successful working.

Boring for petroleum is being carried out at Glenleigh, Penrith, and a depth of 2,500 feet has been reached. Natural gas and brown oil have been encountered.

In Queensland also test wells have been sunk, although geological reports have hitherto not been favourable to the existence of free petroleum. It is considered by some reports, however, th t the wells have not been sunk deep enough to make the tests conclusive, and further trials are now being carried out at Roma, in the north-east of Maranoa province. Shale deposits occur near Gladstone, Port Curtis province, in the Ipswich District of Moreton province, and near Toowoomba, in Darling Downs province.

Bounties of 2*d.* per gallon on the output of kerosene and 2*s.* 6*d.* per cwt. on paraffin wax have been allowed by the Commonwealth Government. A grant has also been made in New South Wales to assist experiments for the extraction of a motor spirit from Zamia palm. Further, the Commonwealth Government has offered a reward of £10,000 for the discovery of natural oil in commercial quantities in Australia, and a bonus of £5,000 has been offered by the South Australian Government to the person or company that first obtains 100,000 gallons of crude petroleum from a well situated in South Australia, the oil to contain not less than 90 per cent. of products obtainable by distillation.

New Zealand.—Indications of oil have been found in Taranaki Province, North Island. The superficial deposits of audesite lavas and fragmentals and recent sandy debris shroud the sedimentary rocks which consist of claystones, sandstones, and fine conglomerates, ranging probably from Pliocene to Miocene age, for a radius of about ten miles from Moturoa. Beyond this, to the east and north-east of Moturoa, the sedimentary rocks appear at the surface as alternating beds, and are traceable to Mohau, fifty miles from Moturoa, the beds passing downwards, probably conformably, into limestones, claystones, and sandstones, with coal seams. Structurally these rocks seem to

form part of a great monoclinal fold, dipping from Mohau towards Moturoa, with minor cross-wells in the form of anticlines, and synclines of sufficient importance to have influenced the position of subterranean reservoirs of petroleum.

A large number of holes have been drilled to depths of from 2,000 to 5,000 feet, but so far without any commercial success, although oil has been obtained in small quantities. Further efforts are being made to develop the field with Government assistance in the way of payment of wages, of the cost of coal, etc. Operations have also been carried out in the Gisborne and Wairarapa districts, North Island, and at Kotuku and Chertsey, South Island. At Kotuku small flows of oil have been obtained at shallow depths, but so far no wells have given profitable results.

Tasmania.—In the neighbourhood of Latrobe and Railton, county Devon, shale deposits are found of an average thickness of 4 feet, and estimated to contain about 5½ million tons. This shale, which is of a tough, brown, laminated composition, and rich in carbonaceous matter, is peculiar to Tasmania, and is known as "Tasmanite"; its average yield on distillation is about 40 gallons of crude oil per ton. The latter is a heavy, dark olive-green liquid, with a specific gravity varying from ·940 to ·950. It burns readily with a strong luminous flame.

It may not be without interest if I now endeavour to explain how oil is discovered, and how it is found, stored in the bowels of the earth, and at the same time if I say a few words on the history of the industry.

Although petroleum has been known from time immemorial, it is interesting to note that the modern petroleum industry really had its birth in England, in spite of the fact that for generations crude oils have been used for illumination purposes in the East.

It was in 1847 that natural petroleum was first worked on a commercial scale at the Riddings Colliery in the Midlands, not far from the present zone in which test-drilling is being conducted by His Majesty's Government, under the direction of Lord Cowdray. And it was from this oil that illuminating oil was first distilled. Here Young commenced his labours which ultimately established the Scottish shale industry.

In 1859, some twelve years after the working of oil at the Riddings Colliery, the famous Drake Well at Titusville, in Pennsylvania, established the possibility of obtaining oil in commercial quantities by boring; and Drake's success gave birth to the petroleum industry in the United States, which now produces over 50,000,000 tons of oil per annum, out of the total world's production of something over 72,000,000 tons per annum. Prior to 1871, crude oil, except in the East, was used chiefly for medicinal purposes, and was considered an infallible specific for all kinds of ailments.

Rapid Growth of the Industry.

The great oil industry, as we know it to-day, is therefore only some sixty or seventy years of age. The rapidity with which it has advanced, and the numerous uses to which oil and its products have been put, mark an epoch in the advancement of engineering and chemical science, which may almost be claimed to be revolutionary. Before the oil industry came into being, "half the world literally lived in darkness and without any conception of means of transport, as we know it to-day."

Petroleum in the crude state, whether derived from a flowing well or from retort, is a complex mixture of hydro-carbons, only dissimilar in molecular degree from the complex hydro-carbons of which coal is composed. The hydro-carbons which constitute the main bulk of most petroleums belong to what is known as the saturated paraffin series. The first four of this series—starting with methane (CH_4)—are gases; the next three—pentane, hexane, and heptane—are highly volatile liquids constituting the bulk of "petrol." Some petroleums are also included in the olefine series (ethylene C_2H_4).

Petroleums contain certain admixtures of sulphur, nitrogen, and oxygen derivatives in comparatively small proportions, which are more or less impurities, and have to be removed in the treatment of the product for commercial use.

Now, how is this crude oil met with in Nature? Where is it found? How is it prepared and distributed for use?

Being a liquid, natural petroleum is capable of migration within the pores of the containing rock, and of being concentrated within geological boundaries. It is owing to this characteristic that accumulations of crude petroleum on a commercial scale are possible. Given a spongy rock, bedded between two impervious strata, you can readily imagine that oil would slowly percolate by gravity into the lowest parts of the sponge. Doubtless, this is what would happen were it not that these porous zones are also

filled with water, so that instead of the oil finding its way to the lower reaches, it floats on the top of the water, oil being lighter than water, and becomes concentrated or trapped into the upper reaches of whatever space is available. The form of this space depends upon the geological structures; anti-clinal or saddle-back folding being the most common form.

Oil so accumulated is usually under pressure, from which it may be released in the form of flowing wells or spouters when the containing stratum is pierced by a borehole.

The resource and experience of the geologist are necessary to indicate where these deep-seated reservoirs exist, and the skill of the engineer is brought into play in tapping these structures with the drill in such a manner that the pent-up energy is usefully employed in forcing the oil to the surface, and in securing the oil pocket from the influx of water lying in the upper strata, which may ruin what otherwise would be a remunerative deposit of petroleum.

It is not infrequent that surface indications of oil exist along the outcrops, and these indications, such as seepages of gas and oil, mud volcanoes, oil-stained sands, etc., when properly examined, may give useful data as to the potential oil-bearing value of the underlying structures.

After test wells have proved the existence of these underground supplies of oil, systematic drilling is proceeded with, the distance apart of the oil wells being governed by many factors, such as porosity and thickness of the oil beds.

Colossal waste resulted from competitive drilling, owing to each landowner endeavouring to drain as much as possible of the oil pool. Waste has resulted, not only from the number of unnecessary wells and from the failure to provide storage and transport facilities for the valuable product when obtained, but also from the inefficient work done in the scramble for oil. Such panic procedure frequently completely destroys a productive zone by allowing water to gain access to it. It has been estimated that such indiscriminate drilling and inefficient work has resulted in the loss of over 50 per cent. of the potential petroleum production of the United States.

It was on account of this factor that the British Government was led to take steps to regulate the petroleum industry in this country from its inception, and should a petroleum industry be established in the United Kingdom, the wisdom of this policy will be fully demonstrated.

In order that no opportunity should be lost of helping to meet the serious shortage of petroleum products during the war, it was decided that steps should be taken to determine the existence or otherwise of natural petroleum in this country, and Messrs. Pearsons, on behalf of the Government, commenced drilling operations in Derbyshire, Staffordshire and the Midlothian district of Scotland. Of the eleven wells sunk, one only (that at Hardstoft) has so far reached the productive stage; oil being encountered at this well in May 1919, at a depth of 3,077 feet, and the flow of oil has been continuous to date, at the rate of about one ton of oil a day. With regard to the remaining wells, owing to various causes, only one other has at present reached the stage at which evidence, either negative or positive, is forthcoming, but sufficient has already been secured to indicate that the test was fully justified. Indeed, there does not appear much reason to doubt that oil in commercial quantities will be forthcoming in England, but it will take years to develop fully.

TRANSPORT.

When oil comes out of the wells, it is usually run through pipes into storage tanks. The commercial production of oil is dependent upon transportation, which is in most cases accomplished by means of pipe lines, tank ships and tank cars. The storage tanks, which are situated in the oil-fields, and are sometimes called tank farms, are generally connected with the gathering lines (about two inches in diameter) of the pipe line system, through which the oil is conveyed to large storage tanks situated near enormous pumping plants. These draw the oil from the storage reservoirs and drive it under pressure into the main pipe lines (varying from eight inches to 12 inches in diameter); and through these main pipe lines the oil is transported hundreds of miles, intermediate pumping-stations being usually placed at distances of thirty to sixty miles along the main pipe lines. In the United States there are over 100,000 miles of main pipe lines, and they transport approximately 100,000 barrels of crude oil per day with greater facility and at lower freight rates than the oil could be shipped on the railways. The question of pipe lines is a very important matter, because even a producing oil-well is of no commercial value unless it is possible economically by means of convenient transportation to send the oil to market.

Refining.

Crude oil when obtained is subjected to refining processes, and by fractional distillation the various grades of oil known in commerce are secured. These vary from lubricating oil and greases to fuel oil and petrol.

I have endeavoured to show you how far it may be possible to find oil in various parts of the Empire, and how the oil is removed when found, and I am sure you will realise how much it must be the duty of every citizen of this great Empire of ours to stimulate the scientific search and exploitation of areas which, by the geological age and structure, are worthy of examination. I cannot conclude my lecture without paying a tribute to Mr. Walter Long, the First Minister in Charge of Petroleum Department, who piloted the Empire and the Allies in the difficult problems connected with petroleum supplies through the most perilous period of the war, and to Mr. Pretyman, who has been good enough to preside to-day.

Mr. Pretyman was probably the first to see with a statesman's clear vision the coming of the oil age and the need for an Empire Policy on oil. For the past twenty years he has devoted the closest attention to the subject, and has sown seeds, the fruit of which is now being gathered. For his foresight and pioneer work this country and the Empire owe a debt to Mr. Pretyman which cannot be readily measured, but which must not be forgotten.

DISCUSSION.

The Chairman, in opening the discussion, said the author had referred in much too flattering terms to his (Mr. Pretyman's) connection with the question of the use of petroleum by the Navy, which originally arose when he held an official position at the Admiralty at the time the Sea Lords, amongst whom was Lord Fisher, made up their minds that petroleum was to be the fuel for future use in the Navy. As the author had pointed out, the amount of petroleum production in the British Empire was very much below its needs, and it was quite obvious that in war-time the nation could not afford to depend upon outside sources, particularly for the Navy. Every one realised the enormous value which our coal supply had been to the Navy in the past, and if this country was to remain in a pre-eminent naval position it was necessary to secure adequate supplies of fuel of all kinds. He was fortunate enough, when he occupied the position of Civil Lord to the Admiralty, to obtain the assistance and advice of the late Sir Boverton Redwood, through whose great knowledge the Admiralty was able to take advantage of the concession which Mr. D'Arcy had obtained in Persia entirely "on his own" as a private individual. But for the information given to the Admiralty by Sir Boverton Redwood at the time there was a possibility that the control of the Persian oil-fields would have passed into the hands of other nationals; but, fortunately, through Mr. D'Arcy's patriotism and the country waking up in time, that concession came into British hands. Any one who realised the position in which the country was as regards petroleum supplies would have been something less than sane if he had not at that time taken care to devote every possible opportunity at his disposal for the advancement of the interests of the Empire. Difficulties had occurred again and again in connection with the history of the problem. The incidents to which he had referred occurred in 1901 and 1902, and unfortunately some years afterwards the Government of the day was more bent upon economy than upon realising the possible future needs of the country. The position we held was then very nearly lost. By the patriotism of certain private individuals sufficient hold was, however, kept, so that when the position was again realised at headquarters this country was able to maintain the control. That had been of enormous value during the war, and he believed it would be of greater value in the future. No man could measure the possibilities of petroleum discoveries in the future. It was impossible for any one to get up and say that the petroleum supply of the world was always going to be less than the world's requirements, but it could be said that the petroleum in sight at the present time was too little for present-day needs and, that being so, it was obviously vitally important to increase it. This country was interested, not only in the very important subject of the petroleum supply of the world as measured in tons, but in the petroleum supply available in those countries where there was a surplus. Seventy per cent. of the petroleum supplies of the world were in the United States, practically the whole of which was required there and could not be exported to this country. Therefore a much smaller quantity in Persia or Mesopotamia, where the supply was likely to exceed the local requirements, was of more interest to this country than a vast supply elsewhere which would never be available. Consequently, on looking into the matter from the point of view of the needs of the Empire, the Government had concerned themselves mainly with two general sources of supply, one within the Empire itself, which was the best for all concerned because, subject to geographical limitations, it was available both in peace and war, and the other outside the Empire, where there was a surplus over and above the requirements of the country of origin, and where the route

from that country to Great Britain could be adequately protected. From that point of view Persia was most important. The Middle East was not so far from this country, particularly if a pipe-line could be carried from the oil-fields to the Mediterranean, so that transport round Arabia, two or three thousand miles, could be avoided. He believed the Anglo-Persian Oil Company were already taking steps in that direction. The Burmah Oil Company had also been very closely associated with the early efforts that were made to obtain an oil supply for the British Empire, and it was largely due to the patriotism of Lord Strathcona and the technical knowledge and financial assistance of that Company that the Anglo-Persian field had been developed. Lord Strathcona took the presidency of the syndicate which established that field. With regard to the very important controversy that was raging in the Press on the subject of the rights and opportunities of British and American subjects in the development of oil-fields, he thought that so far from the American oil magnates having any complaint against this country, the boot was rather on the other leg. The attitude of the British Government had always been to leave its nationals unsupported, while the Governments of other nations, not excluding the United States, looked after the interests of those who attempted to use their financial resources for developments outside their own countries. Where other Governments were not supporting private enterprise he thought our Government ought not to interfere to give its own nationals an advantage over the rest; but where nationals of another country were being supported by their Government then our nationals should receive similar support from the British Government. The figures showing that the United States possessed 85 per cent. of the world's production, while the British Empire possessed less than 5 per cent., could not be contradicted. He did not think legitimate complaint could, therefore, be made if, in view of the vital need for fuel for the development of the national resources of any nation, this country tried by every legitimate means to extend its 5 per cent. a little further. He was perfectly certain, however, that every Englishman wished for fair play. They remembered how much they had been helped by supplies of oil from the United States during the war, and were duly grateful for them; but after all, in the war every Ally put all its resources into the common stock. America happened to have more petroleum than England, while England had more ships than America, so he did not think there was debt on either side in that way. There was a bond of unity between the two parties, who worked together for the common cause, knowing that every effort must be made in order to win the victory. Now that peace had been brought about and normal developments were recurring, the people of this country were anxious that those territories which were under the control of the British Empire should, as far as possible, be developed by associations which were British; at any rate, that where British enterprise had obtained concessions by ordinary competition the holders of the concessions should not be deprived of them simply because they were British, and because there was now British control over those countries. He congratulated the country on having a Petroleum Executive which could advise the Government of the day at any time on what its petroleum policy ought to be. He had had that object in view for something like twenty years. During his two or three terms of office he had seen that every department of the State had its own separate petroleum policy suited to its own particular departmental requirements at the moment; there was no such thing as a Government policy at all. If the country was to have petroleum it was essential that a competent department should exist with full technical knowledge of the petroleum industry and possessing accurate information in regard to the history of the petroleum world. This country had fallen behind over and over again when it came to negotiations with some other country, simply because it had more goodwill than accurate local knowledge and information. It was necessary that the Government of the day should have at its disposal the most accurate historical, technical and commercial knowledge relating to petroleum in order that it might be in a position to negotiate fairly and honourably, and without a Petroleum Executive which could prevent contests between independent departments it was impossible for this country to have justice done to it by its Government in the vital petroleum matters which concerned it so deeply.

SIR GEORGE T. BEILBY, LL.D., F.R.S., said the author had referred to the fact that, prior to the advent of petroleum sixty years ago, more than half the world was in darkness. The great thing that happened through the discovery of oil, and James Young's showing that it could be distilled from shales, was that a new source of light was provided which could be used in every humble household, and the humble households all over this and many other countries were within a few years in possession of a light which their parents had never dreamed of. That was the main feature of the industry for many years, because neither in Scotland nor in America were the heating and power of the products realised. It was probably when Russia began the development of the great Baku supplies of petroleum that the use of petroleum as a source of power and heat was understood. The Russians, not having suitable coal supplies, proceeded to fire

their steamers on the Volga, and their railway engines with the less volatile part of the natural Baku oil. The rapid changes that had taken place since that time might be ascribed to the increasing appreciation of liquid fuels as a source of power and heat. Their old importance as a source of light for the world had practically gone, but year by year their increasing importance as sources of heat and power had become manifest. During the past year alone the development of public interest in the subject had become almost frantic, but he thought there was an absence of the proper sense of proportion in dealing with it. He did not seek to minimise the immense importance of the nation using every effort to secure the widest possible supplies of natural petroleum, not only during peace, but war, but it was necessary to continue to think in terms of fuel, and if they did so it was impossible to ignore the coal supplies of the world. The world's output of petroleum was at present of the order of 75,000,000 tons per annum, while the world's output of coal was of the order of thousands of millions of tons per annum, so that in all developments of power for transport the greatest attention must be directed to the cheapest form of fuel, namely, coal or coke, and that point required emphasising. It was very encouraging to see on the roads an increasing number of heavy motors and lorries driven by steam engines and gas engines, and development along those lines would go a long way towards reducing the extreme pressure and anxiety which everyone felt owing to the shortage of liquid fuel. The first use of liquid fuel in the form of motor spirit should be for air transport, because at the moment there was nothing to take the place of petrol for transport in the air. In the second place, nothing could take the place of liquid fuel for the Navy, and at present a great danger existed in regard to the supplies for Naval purposes owing to the rapid increase in the requirements of the mercantile marine. In that direction he trusted the authorities would preserve a due sense of proportion, and that every encouragement would be given to the use of the cheapest forms of thermal energy for all kinds of transport for which they were available, because, from what was stated in the paper, it was perfectly certain that there would not be a superfluity of liquid fuel for a long time to come. It was, therefore, a national duty to see that the best advantage was taken of solid fuels, and that all transport that could be run by their aid should be worked in that way.

Mr. A. H. Ashbolt (Agent-General for Tasmania) said that Australia and Tasmania were only infants in oil production, but the question was one of considerable moment to them because the distant parts of the Empire realised the importance of communication with the Old World. The various States had accordingly entered into an agreement with the British Government and the Anglo-Persian interest to erect oil refineries in Australia in the endeavour to make the country partly independent of coal supplies. It was quite possible that at some later date Australia and Tasmania might be self-supporting, but at present they were far from that position. The fact that Australia produced about 10,000 tons of oil fuel per annum was an indication that it possessed potential possibilities as a future supplier of the Empire. Australia covered a territory slightly bigger than the United States of America, and if from its tertiary rocks 10,000 tons of oil fuel were produced per annum, a progressive policy would at a later date help the country to supply not only its own requirements but contribute to the Empire, of which they were proud to be a partner. Mr. D'Arcy, to whom reference had been made, was an Australian, and the fact that his work had been of such considerable benefit to the Empire was a source of gratification to every Australian. Tasmania possessed huge deposits of limestone, and he would be obliged if the author could state whether in his opinion that was an indication that there were big deposits of oil in Tasmania. An endeavour was now being made to introduce capital to develop the shale fields of Northern Tasmania, where it was thought possible that there might be a large supply of oil fuel, although at present its value as a petrol producer was not known. He desired the adoption of an Empire policy in regard to oil which would prevent overlapping of the proper exploration of possible fields for the benefit of the Empire, and he would be glad to know if the Government Department over which the author presided had funds available for exploration in that part of Tasmania in which he (Mr. Ashbolt) was particularly interested.

Dr. W. R. Ormandy emphasised Sir George Beilby's remark that the total oil production of the world was a mere decimal of the amount of coal production, and also joined with him in emphasising the sinfulness of using any oil for mere steam-raising purposes other than in the Navy, and even there only in times of stress. To use oil for steam-raising purposes which could be cracked into more volatile fractions was a scandal. The people in this country had in the past been most reckless and uneconomical users of coal. They were now starting on an oil age, and it was sincerely to be hoped that the same policy of recklessness which had marked the utilisation of coal would not be continued in the case of oil. It was not possible to substitute anything for volatile fuel on a large scale in connection with high-speed internal combustion engines. In so far as volatile fuel could be produced from crude oils it should be produced, because very few people realised that the high-

speed internal combustion engine was the third largest industry of America, and that it would soon be the third largest industry in the manufacturing world. If volatile fuel was too dear or was not available it meant that that third largest industry of the world would be severely damaged and its activities kept down when internal combustion engines were becoming more and more that protean form of developing energy which would replace hand labour, which was growing so expensive that people could not afford to pay for it. He hoped the paper and Sir George Beilby's remarks would penetrate into the last recesses of the Press. Although the Press was perfectly willing to pay a man a large salary to advise as to what was correct or wrong in the Drama, and still larger sums to a clever musical critic, they would not pay a cent to anybody dealing with science, and it was only by papers such as the author's penetrating into the Press that there was the slightest prospect of getting any daylight into the brains of the average British public.

Sir Marcus Samuel, Bt., in proposing a vote of thanks to Sir John Cadman for his illuminating paper and to Mr. Pretyman for presiding, said he was in a somewhat difficult position because he had not always seen eye to eye with the Chairman. He thought the Chairman would agree with him that the public spirit of the eminent men he had mentioned, Lord Strathcona, Sir John Cargill, and the directors of the Burmah Oil Company, would have been able to secure for the British Empire the Persian oil fields they held without the intervention of the British Government. He foresaw what would happen. The moment the British Government as such became traders in petroleum and competed with the companies from which they received large taxation, trouble was bound to occur sooner or later. So soon as the British Government became interested as partners in petroleum other Governments took up the same attitude; and whilst disputes between companies were comparatively unimportant because they soon somehow or other settled their differences, disputes between Governments came under quite a different category. It certainly could not be in the national interest that the jealousy of France and of the United States should be aroused by the British Government being in the trade, when if left to private enterprise no such exception could possibly be taken. He desired to associate himself with the praise which had been bestowed upon Sir John Cadman, who, in the extremely difficult position he occupied of having to reconcile many conflicting interests, had shown himself a man of tact and ability and had rendered the utmost service in his position as Adviser on petroleum subjects. With regard to Mr. Ashbolt's remarks, the association of the Government with the Anglo-Persian Company was most unfortunate, because if Mr. Ashbolt would study the map he would find that the Australian Government had at their disposal oil from British territory, which they might equally have used if they had chosen to do so, which happened to be just half the distance away from Australia that the Anglo-Persian oil-fields were. He put it to Mr. Ashbolt that there was no particular merit in oil that came from a British Protectorate, even if it was produced by the aid of British Government money, when it could be got equally well from another part of the Empire, if it was not held that that oil was tainted because aliens had helped to develop it. For many years to come Great Britain would have to depend upon foreign supplies, and it would be impossible to adopt a more stupid and foolish policy than to alienate the sympathy and take away the assistance which those foreign countries had always rendered to this country. If the unfortunate policy were to prevail that each country could only work oil through its own nationals he was afraid British capital would be in a very perilous state. For instance, if a revolution occurred in Mexico, was it to be said that because the Government changed a concession previously granted should be cancelled, and was it to be said that although there were British concessions in Rumania only the nationals of that country could hold a concession in future? The argument came with infinitely stronger force when they heard that the Government of the United States had decided that if there was not to be reciprocity there should be discrimination in America against countries which discriminated against American citizens. Those were practical considerations which he was sure the author would take care to bring prominently before the Government, because this country could not afford to quarrel with the whole world over the question of oil supply.

Sir Harvey Adamson, K.C.S.I., in seconding the motion, said that some popular fallacies had been knocked on the head by Sir John Cadman's paper, and he was sure everyone was glad to hear that the policy of the Government as advised by the Petroleum Executive, was not quite so bad as they might be led to expect from their perusal of the daily papers.

The resolution of thanks was carried unanimously.

Sir John Cadman, in reply, said he entirely agreed with the remarks Sir George Beilby had made. He had indicated in his paper that there should be no rivalry between oil and coal, but that they should be taken together as a measure of energy, and that coal should be put into a position in which it could be used as economi-

cally as oil. Coal had been used in the past in the most disgraceful way. The time was not far distant when people would not be permitted to burn coal in their fireplaces, but only the residue that was left after the volatile portion had been taken off and passed into commerce to compete with oil. In reply to Mr. Ashbolt's remarks he could only say that sometimes oil was obtained from limestone. It offered inducements for careful examination, and he hoped the Tasmanian Government would not fail to have their territory geologically examined. Sir Marcus Samuel had outlined some of the difficulties connected with the general question. It had been said that the Anglo-Persian Company, owing to the fact that it had a certain amount of Government capital in it, was under the influence and domination of the Government. It was his privilege to act for the Government, and he assured those present that he had no more power over the Anglo-Persian operations than he had over the operations of Sir Marcus Samuel's companies. Some of the points which Sir Marcus had raised might be argued on high political grounds. All he could say was that, during the period he had been in touch with the activities of the oil companies, they had been of the greatest benefit to the country, and he acknowledged the Government's indebtedness to people like Sir Marcus Samuel, Mr. Deterding, Sir Charles Greenway, Lord Cowdray, and others who were running those great organisations. While they were prepared to come to meetings of that character and to discuss in a friendly way certain phases of the question, when it actually came to the point none of them was lacking in his support of the Empire. He made that remark, because it might be thought from what Sir Marcus Samuel had said that there was a feeling somewhere between the interests that ran the different companies. The feeling was only the froth on the surface; they were really out to do business in the great Empire to which they belonged, and they were doing it in the interests of and to the credit of the Empire and themselves.

The meeting then terminated.

THE CHINESE MARKET.

The following information as to the outlook for British trade in China is taken from a special article in the *Board of Trade Journal*:—

As a belligerent China came late into the war (August, 1917), and was not called upon by her allies to take any military part in it. She enjoyed exceptionally good crops during the war years, and the closing of European markets was offset by the expansion in business with Japan and the United States. The years 1916, 1917 and 1918 established records as regards value in China's foreign trade. She was forced, by the pre-occupation of the European Allies, to turn more and more towards Japan, and both her Northern and Southern Governments pledged valuable mining and industrial concessions with that country in return for loans. But this enforced dependence upon Japan had one beneficial effect in that it emphasised, in the minds of the more thoughtful among the Chinese, the contrast between the weakness and backwardness of China and the strength and development of Japan. This glaring contrast between Oriental peoples did much to rouse a small healthy public opinion in China to demand radical reforms in government and to seek after the development of transport and industry. The old anti-foreign feeling is disappearing, and the desire is awakening that China should avail herself of foreign skill and science in the development of the country. The British people have the advantage of belonging to a country which has always pledged itself to maintain China's integrity, and their reputation for just dealing stands very high in the eyes of a race which is pre-eminently honest in its commercial operations. No foreigners have been more successful than the British in establishing friendly personal relations with Chinese customers. We understand them as well as any modern Western people can understand so ancient and proud an Eastern race.

The United States and Japan.

Although there was an inevitable shrinkage in the volume of China's foreign trade during the war the value steadily increased. America is probably the most serious competitor of Great Britain at the present time, for though trade with Japan expanded enormously during the war years, the thorough and persistent boycott of Japanese goods, established in 1919, has dealt a blow from which it will take the trade some time to recover. American business men of all kinds are flowing into China, and over 100 American firms have opened in Shanghai alone during the past year. American banks, shipping companies, land investment companies, and wholesale and retail importers and exporters are all represented. Ninety per cent. of China's imports and exports pass through the ten principal Treaty ports, of which 40 per cent. is claimed by Shanghai. Big British merchant houses have been established in these ports for many years, in some instances for nearly a century, and through their long-established Chinese connections these firms remain —at least for the present—the best channels through which British goods may be sold in China. It is difficult for the new American competitors to rival the big British house, either in the extent of its connections or in its repute for financial stability. Great Britain still possesses the advantage of old connections.

Great Britain's Share in the Trade.

Thus a year's experience of trade after the war shows that Lancashire has definitely and completely re-established the position which the shipping

and other troubles during the war years compelled it to relinquish. Neither Japan nor America has been able to supply rivals to the high-grade dyed and figured cloths of British manufacture, and the moment the Chinese market could look to Lancashire for supplies British piece-goods were eagerly welcomed. The Japanese are making only slow progress against us in dyed cloths. Even in the greys section, including sheetings, shirtings, drills and jeans, upon which our competitors concentrated, British materials have come back into their own. The personal factor counts for much in China, and the British trader who knows and is known in the market retains his pull in spite of a temporary absence. If the year 1919 be considered as a whole and regarded as a test, it is safe to say that British trade is as sound as, if not sounder than, ever. Its qualities of permanence and vitality have been tested and have made good.

Although for the moment Japan has domestic difficulties to contend with, as well as the Chinese boycott to wear down, her competition is a more permanent factor to be faced than that of America. It is fully recognised that Japan's future as a great commercial country depends upon her retention and development of the Chinese market. It is a limitless market, opening out from her very doors. America might withdraw without serious loss; Japan must hold on. There are so many styles of cloth produced by the three countries that active development within China herself may offer scope for all three. Neither America nor Japan can supplant Great Britain; neither can Great Britain wholly supplant them.

The most serious danger for us is the advance in prices. At present the difficulty in securing textile machinery hampers the expansion of China's local spinning and weaving mills. But time will remove this obstacle, and should the reduction in working hours and the advance in costs in Lancashire continue indefinitely there may come a time when British goods will no longer be able to hold their own either against the local products or against those of Japan a d America. During the past year China has been starving for goods and willing to pay almost any price for our products, but the market will not always be starving. We shall then have to compete in prices as well as in quality and style.

The Future of British Trade.

China, the oldest of the world's great markets, is still undeveloped. Her 350 millions of people buy abroad little more than twelve shillings-worth a head. As she develops her internal resources, and more fully utilises her infinite resources in cheap coal and cheap labour, there must be an expansion in her exports and a corresponding expansion in her imports of foreign goods. At the same time it should be recognised that China will become at no distant date an important manufacturing country, and put forth native goods in competition with many of those which are at present imported. It will be well, therefore, for our manufacturers who have a deep interest in retaining the Chinese market, and in sharing in the coming expansion, to consider the establishment of branch factories in China in which to produce those cheaper lines of goods which must in time undersell the corresponding imported articles. China not only has vast coal measures; she produces, or can produce, practically every form of raw material required for industrial and commercial purposes. She is even experimenting with rubber in South China.

Local British Factories.

Several well-known British manufacturers have found it convenient to establish branch factories in Shanghai and other Treaty Ports in order to supply the China market with such articles as soap, candles, cigarettes, etc., which can be made locally as well as and more cheaply than in the United Kingdom, and it is probable that this example will shortly be followed by others. British manufacturers need not fear this competition, since for many years to come these local factories will only be able to turn out goods of inferior quality which will compete more with the Japanese than the British article, and as the country develops and the standard of living rises, a demand will grow up for higher priced goods of better quality. As an illustration, it is reported that the local agent for a well-known firm of soap-makers can sell more of the imported British article than he can of a cheaper soap made in his Shanghai factory.

Demand for Machinery.

This industrial development has naturally created a demand for foreign machinery, which, owing to the cessation of supplies from Europe and latterly from America caused by the war, has now assumed very considerable dimensions. From all parts of China come orders and inquiries for textile machinery, railway material, electric light and power plants, motor cars and lorries, which our engineering firms are unfortunately only able to cope with to a limited extent, as they have difficulty in obtaining fixed quotations and guarantees of delivery from manufacturers in the United Kingdom, who are apparently fully occupied with home orders. This is particularly regrettable, in view of the enormous expansion in the engineering trade of China that is bound to take place within the next few years, and the keen competition on the part of the Americans, Germans and Japanese. It is desirable that home manufacturers, with an eye to the future, should see their way to give priority to some orders at least from China in order to keep British manufactures before the Chinese. It must be remembered that machinery being still comparatively rare in China, each complete equipment of, say, a cotton mill or an electric light plant attracts far more attention than it would in countries where industries are more highly developed, and, indeed, serves as the best of all advertisements for not only the particular maker of the goods, but for the manufacturers of the

maker's country in general. There is, for instance, a rapidly increasing demand for motor cars in Shanghai, Tientsin, Hankow, and other ports, and rich Chinese will pay almost any price for well-known European makes. Yet since the Armistice not one single British car has been sent to Shanghai, although local agents have implored makers to send out a few cars—for which payment would, of course, be made—for advertising purposes. The result is that American cars are literally pouring into the country and selling at fancy prices, and American garages are springing up in all the large cities.

NOTES ON BOOKS.

COMPRESSED AIR POWER. By Albert W. Daw and Zacharias W. Daw. London: Sir Isaac Pitman & Sons, Ltd. 21*s*. net.

During the last twenty-five years great advances have been made in the use of compressed air. It is not only employed to transmit power to distances, but it is also largely used in mines, collieries, engineering works, tunnelling, quarrying, sewage works, chemical works, breweries, etc. Again, it is employed for pneumatic drilling, riveting, etc.; in foundries for cleaning castings and mouldings; on railways for braking trains, and operating switches and signals; by the Post Office for the conveyance of parcels; by engineers for caissons to reach solid rock in under-water excavations; and its application to industrial purposes is constantly developing.

In view of the great and growing importance of the subject, a handbook dealing with the principles of compressed air power on scientific lines is to be warmly welcomed. The authors begin with the atmosphere, describing its composition, pressure, temperature, etc.; the fundamental physics of air and gases are next treated; the compression, expansion, exhaust and flow of air and gases are fully dealt with, formulæ are deduced for making the necessary computations, and practical examples are stated and solved. A special section is devoted to the air lift pump, and the lines on which it should be designed are indicated. Various types of air valves, controls, and receivers for compressors are described and illustrated; information is given as to the washing and filtering of air before it reaches the compressor, and as to the reheating of compressed air before use in the air motor.

UNION TEXTILE FABRICATION. By Roberts Beaumont, M.Sc., M.I.Mech.E. London: Sir Isaac Pitman and Sons, Ltd. 21*s*. net.

Professor Roberts Beaumont is generally recognised as one of our highest authorities on the rapidly developing subject of union textile fabrication. He has a very wide experience of the properties of raw textile materials of all kinds, and their manufacture into woven fabrics. The present volume, therefore, will be found to possess singular interest and value for manufacturers and investigators whether connected with the cotton, the wool, the flax, or the silk trade. It contains a great mass of information which, however, is methodically arranged, and rendered easy for reference, while the 204 illustrations are of great assistance in making clear the meaning of the text.

The book contains many suggestions which should be helpful to those who are endeavouring to produce new cloths. It deals fully with the selection, blending, and preparation of bi-fibred yarns, particularly of wool and cotton and union twist yarns for fancy or piece dyed goods. The section on colourisation and textual toning contains numerous examples, while the use of union twist yarns in combination with single, double, and multiple weave structures is fully described and illustrated. The last part deals with woven unions and simple ornament obtained by various methods of drafting, and by the employment of special weaves adapted to the production of woven fabrics of light structure.

GENERAL NOTES.

PORTUGUESE SALT.—According to the American Consul-General at Lisbon, the annual production of salt in Portugal for export is 150,000 to 200,000 tons. The stocks of 1917 and 1918 are still unsold. Aveiro in the north, Setubal on the river Sado, and the Tagus are the main salt-producing districts in Portugal. The exportation of Portuguese salt before the war was chiefly to the Netherlands, France, Newfoundland, Norway, Sweden, and Ireland. After the war conditions changed; the Netherlands, Sweden and Norway now buy mineral salt from Germany, and France makes its purchases from England. In Norway the importation of salt will be eliminated soon, owing to the building of large electrical sea-water evaporating plants for obtaining salt direct from the sea. The representatives of the Portuguese salt industry have called the attention of the Government to their difficulties.

LONG STAPLE COTTON FOR TYRES.—The United States Department of Agriculture, according to the *Journal of the Textile Institute*, is undertaking a great amount of work in the effort to develop adequate supplies of long-staple cotton for use in motor-car tyre manufacture. A cotton had been brought from Egypt, and, by careful breeding and selection, the specialists had developed a long-staple cotton which was probably the best in the world—one that would add greatly to the life of every fabric made from it. Twenty million dollars worth of that cotton was produced last year in the desert country of the south-west where practically nothing grew before, and the production was expected to increase greatly this year. As the American-Egyptian cotton industry develops, more of the cotton will go into articles other than automobile tyres, and considerable quantities of clothing will be manufactured from it.

Journal of the Royal Society of Arts.

No. 3,533 VOL. LXVIII.

FRIDAY, AUGUST 6, 1920.

***All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.* (2)**

PROCEEDINGS OF THE SOCIETY.

SIR GEORGE BIRDWOOD MEMORIAL LECTURE.

A meeting of the Indian Section was held on Friday, June 18th, 1920; THE RIGHT HON. LORD MESTON, K.C.S.I., LL.D., in the chair.

The lecture delivered was—

THE ENDURING POWER OF HINDUISM.

By SIR VALENTINE CHIROL.

I esteem it a very great honour to have been invited to deliver the first of the annual lectures founded by this Society in respectful and affectionate memory of one of its oldest and most distinguished members, the late Sir George Birdwood, whose personal friendship it was my privilege to enjoy. There is, indeed, little I can add to the admirable tribute rendered to him in the Society's *Journal* shortly after his death three years ago. If East and West can meet, they met in the heart of one who was as passionate and understanding a lover of India as of Britain. To the two-fold flame that burnt in him up to the last day of his life I can speak with more authority than to the invaluable work which he did for over forty years as a member of the Royal Society of Arts, or to the wealth of recondite knowledge, combined sometimes with an equal wealth of exuberant imagination which he was always ready to pour forth for the benefit of a less favoured public. The last volume of the great "Life of Lord Beaconsfield," begun by the late Mr. Monypenny and just completed by Mr. Buckle, produces interesting evidence that it was Sir George Birdwood who started in the observance of Primrose Day (but not the Primrose League) the still popular cult of a statesman whom most people would probably have been disposed to associate with some less retiring flower. Mr. Buckle explains the choice of the primrose to commemorate, as it does to the present day, a striking personality which some may still think to have been the greatest, and all will admit to have been the most picturesque figure in the political arena of our times. But the secret of Sir George's fervent admiration for Lord Beaconsfield may, I think, be found in a letter I received from him in the autumn of 1914, when the first Indian Expeditionary Force began to reach the battlefields of France and to fill up the awful gaps in our thin red line, which could not have been otherwise filled before Kitchener's new armies and the contingents from the self-governing Dominions were trained and equipped to follow in the track of our glorious "contemptibles." "India to the rescue," he wrote, "at the call of her Emperor"—with the word Emperor assuredly three times underlined. "And to think there were fools who dared to jeer when Dizzy induced Queen Victoria to proclaim herself Empress of India, and Indian troops were for the first time brought across the black water to Malta." I am quoting from memory, but the labour—and it was always worth it—of deciphering his strange hieroglyphics helped to impress the very words he wrote on one's memory.

It was more than anything else the kindred strain of intuitive understanding for the symbolism in which the Indian mind delights that drew forth his enthusiasm for Lord Beaconsfield. Again and again, during the Great War, he loved to dwell on every incident that showed the heart of India to be in unison with that of the whole Empire, and with his special worship of the Rajputs as the incarnation of Indian chivalry, he seemed to identify all India with the gallant figure of old Sir Pertab Singh, who sought, though he did not find, a hero's death on the stricken fields of France. It has been well said of Sir George Birdwood that "there was nobody quite like him—quaint, crotchety, generous and liberal to a fault, often wise, gener-

ally humorous, frequently eccentric, and especially of late years, inevitably outspoken"—and, I would myself add, a great patriotic soul, whose faith never faltered during the darkest hours of our world-struggle. One may grieve that he did not live to see its victorious issue, but had he seen it, it would hardly have added to the unalterable serenity of mind with which, through good and evil report, he never ceased to believe that it must and would come.

In selecting my subject for this lecture I have been chiefly moved by the desire to find one with which I know that Sir George Birdwood would have been in full sympathy, and I can only crave your indulgence if I cannot bring to bear upon it the breadth and depth of expert knowledge with which he would have approached it. I do not claim, indeed, for a moment to address you as a student, but merely as a layman, who, in the course of inquiries directed mainly to the problems of Indian governance in our own days, has been driven to reflect on the enduring power of that great religious and social system which we call Hinduism as the amalgam that has welded together one-sixth of the human race throughout long centuries of domestic turmoil and foreign domination.

It is not one of the least peculiarities of India that, with a remarkable civilisation of her own which reaches back into remote ages, her early history has only now begun to emerge from the twilight of myths and legends, and cannot even now be traced with any assurance of accuracy nearly as far back as that of other parts of the world which preceded or gave birth to our own much more recent civilisation. The pyramids of Ghizeh and Sakkara, and the monumental temples of Thebes bore ample witness to the greatness of Egyptian civilisation long before the interpretation of her hieroglyphics enabled us to determine its antiquity, and the discovery of its abundant art treasures revealed the high degree of culture to which it reached. Excavations in the valley of the Tigris and Euphrates have yielded an almost equally valuable harvest in regard to Babylonian and Assyrian civilisation, and Cnossos has told us its scarcely less wonderful story. Yet the long line of Pharaohs was coming to an end and Egypt was losing the national independence which she has never once recovered; Nineveh had fallen and Jerusalem was destroyed; Greece and even Rome had already started on their great creative careers before any approximately correct date can be assigned to the stages through which Indian civilisation had passed. India only becomes historical with the establishment of the Sasunaga dynasty in the Gangetic kingdom of Magadha, which centred in what is now Behar, about the year 600 B.C.

As to the state of India before that date, no sort of material evidence has survived, or at any rate has yet been brought to light—no monuments, no inscriptions, no pottery even, in fact, no trace of the handicraft of man; nor any records that can be called in any way historical. Fortunately the darkness which would have been otherwise Cimmerian, is illuminated, though with a partial and often uncertain light, by the wonderful body of sacred literature which has been handed down to our own times in the Vedas and Brahmanas and Upanishads. To none of these books, which have, for the most part, reached us in various recensions often showing considerable discrepancies and obvious later interpolations, is it possible to ascribe any definite date. But in them we undoubtedly possess a genuine key to the religious thought and social conceptions, and even inferentially to the political institutions of the Aryan Hindus through the ages that preceded the emergence of India into history. The Vedic writings constitute the most ancient documents available to illustrate the growth of religious beliefs founded on pure Nature-worship, which translated themselves into a polytheistic and pantheistic idea of the universe and, in spite of many subsequent transformations, are found to contain all the germs of modern Hinduism as we know it to-day—and, indeed, of all the religious thought of India. In the Vedic hymns Nature itself is divine, and their pantheon consists of the deified forces of Nature, worshipped now as Agni, the god of Fire; Soma, the god and the elixir of life; Indra, the god of heaven and the national god of the Aryans; and again, under more abstract forms, such as Prajapati, the lord of creation, Asura, the great spirit, Brahmanaspati, the lord of prayer; and sometimes, again, gathered together into the transcendent majesty of one all-absorbing divinity, such as Varuna, whose pre-eminence almost verges on monotheism. But the general impression left on the Western mind is of a phantastic kaleidoscope, in which hundreds and even thousands of deities, male and female, are constantly waxing and waning and changing places, and proceeding from, and merging their identity in, others through an infinite series of processes, partly material and partly metaphysical, but ever more and more subject to the

inspiration and the purpose of the Brahman, alone versed in the knowledge of the gods, and alone competent to propitiate them by sacrificial rites of increasing intricacy, and by prayers of a rigid formalism that gradually assume the shape of mere incantations.

This is the great change to which the Brahmanas bear witness. They show no marked departure from the theology of the Vedas, though many of the old gods continue to be dethroned either to disappear altogether, or to reappear in new shapes, like Varuna, who turns into a god of night to be worshipped no longer for his beneficence, but to be placated for his cruelty; whilst, on the other hand, Prajapati is raised to the highest throne, with Sun, Air, and Fire in close attendance. What the Brahmanas do show is that the Brahman has acquired the overwhelming authority of a sacerdotal status, not vested merely in the learning of a theologian, but in some special attribute of his blood, and therefore transmissible only from father to son. The Brahman was doubtless helped to this fateful pre-eminence by the modifications which the popular tongue had undergone in the course of time, and as the result more especially of migration from the Punjab to the Gangetic plains. The language of the Vedic hymns had ceased to be understood by the masses, and its interpretation became the monopoly of learned families; and this monopoly, like all others, was used by those who enjoyed it for their own aggrandisement. The dead language became a sacred language, and sacred became the Brahman, who alone possessed the key to it, who alone could recite its sacred texts and perform the rites which they prescribed, and select the prayers which could best meet every distinct and separate emergency in the life of man.

Whilst we can follow in the Brahmanas the growth of a luxuriant theology for the use of the masses which, in so far as it was polytheistic, tended to the infinite multiplication of gods and goddesses and godlings of all types, and in so far as it was pantheistic invested not only men, but beasts and insects and rivers and fountains and trees and stones with some living particle of the divine essence pervading all things; and also the erection on the basis of that theology, of a formidable ritual of which the exclusive exercise and the material benefits were the appanage of the Brahman, we have to turn to a later collection of writings known as the Upanishads for our knowledge of the more abstract speculations out of which Hindu thinkers, not always of the Brahmanical caste, were concurrently evolving the esoteric systems of philosophy that have exercised an immense and abiding influence on the spiritual life of India. There is the same difficulty in assigning definite dates to the Upanishads, though many of the later ones bear the post-mark of the various periods of theological evolution with which they coincided. Only some of the earliest ones are held by many competent authorities to be, in the shape in which they have reached us, anterior to the time when India, as I have said, first becomes historical; but there is no reason to doubt that they represent the progressive evolution into different forms of very ancient germs already present in the Vedas themselves. They abound in the same extravagant eclecticism, leading often to the same confusions and contradictions that Hindu theology presents. The Sankhya Darshana, or system, recognising only a primary material cause from which none but finite beings can proceed, regards the universe and all that exists in it and life itself as a finite illusion of which the end is non-existence, and its philosophic conceptions are atheistic rather than pantheistic. In opposition to it the Vedantic system of mystic pantheism, whilst also seeing in this finite world a mere world of illusion, holds that rescue from it will come to each individual soul after a more or less prolonged series of rebirths, determined for better or for worse by its own spirituality according to the law of Karma, not in non-existence, but in its fusion with God, whose identity with the soul of man is merely temporarily obscured by the world illusion of Maya. Only the inconceivable is real, for it is God, but God dwells in the heart of every man, who, if and when he can realise it and has detached himself from his unworthy because unreal surroundings, is himself God. Akin to Vedantic mysticism is the Yoga system, which teaches extreme asceticism, retirement into solitude, fastings, nudity, mortification of the flesh, profound meditation on unfathomable mysteries and the endless reiteration of magic words and phrases as the means of accelerating that ineffable fusion of God and man. The materialism of the Sankhya and the idealism of the Vedanta combine to provoke the reaction of yet another system, the Mimansa, which stands for the eternal and divine revelation of the Vedas, codifies, so to say, their theology into liturgical laws, admits of no speculation or esoteric interpretation, and seems to subordinate the gods themselves to

the forms of worship that consecrate their existence.

Of all the doctrines that these early speculations evolved, none has had a more enduring influence on Hinduism than that of the long and indeed infinite succession of rebirths through which man is doomed to pass before he reaches the ultimate goal either of non-existence or of absorption into the divine essence. For none has done more to fortify the patriarchal principle which from the earliest times governed the tribal family, and to establish the Hindu conception of the family as it prevails to the present day. For with that curious inconsequence which frequently characterises Hindu thought, even when it professes to be ruled by the sternest logic, the belief that every rebirth is irrevocably determined by the law of Karma, *i.e.*, in accordance with the sum total of man's deeds, good and bad, in earlier existences, is held to be compatible with the belief that the felicity of the dead can only be assured by elaborate rites of worship and sacrifice, which a son alone, or a son's son can take over from his father and properly perform. The ancient *patria potestas* of tribal institutions has been thus prolonged beyond the funeral pyre, and the ancient reverence for the dead which originally found expression in an instinctive worship of the ancestors has been translated into a ceremonial cult of the ancestral manes, which constitutes the primary duty and function of every new head of the family. Hence the Hindu joint family system which keeps the whole property of the family as well as the governance of all its members under the sole control of the head of the family. Hence also the necessity of early marriage, lest death should overtake the Hindu before he has begotten the son upon whose survival the performance of the rites essential, not only to his own future felicity, but to that of all his ancestors depends, and, as an alternative, to mitigate the awful consequences of the default of heirs male of his own body, the introduction of adoption under conditions that secure to the adopted son precisely the same position as a real son would have enjoyed. Hence again the inferiority of woman, whom early marriage tended to place in complete subjection to man. Her chief value was that of a potential breeder of sons. In any case, moreover, she passed on her marriage entirely out of her own family into that of her husband's, and terribly hard was her lot if she were left a widow before having presented her husband with a son. Even if she were left an infant widow of an infant husband and their marriage could not possibly have been consummated, she was doomed to an austere and humiliating life of perpetual widowhood, whilst, on the other hand, if she died, her widowed husband was enjoined to marry again at once unless she had left him a son. To explain away this cruel injustice, her fate was supposed to be due to her own Karma, and to be merely the retribution that had overtaken her for sins committed in a former existence, which condemned her to be born a woman and to die a childless wife, or worse still, to survive as a childless widow. The misfortune of the widowed husband who was left without a son should logically have been imputed in the same way to his own Karma, but it was not. All through life, and in death itself, man was exalted and woman occupied a much lower plane, though in practice this hardship was mitigated for the women who bore sons by the reverence paid to them in their homes, where their force of character and their virtues often gave them a great and recognised ascendancy. However hard the laws that governed the Hindu family might press on individual members, the family itself remained a living organism, united by sacred ties—indeed more than a mere living organism, for the actually living organism was one with that part of it which had already passed away and that which was still awaiting rebirth. It is undoubtedly in the often dignified and beautiful relations which bind the Hindu family together that Hinduism is seen at its best, and the picture which Mr. Bhupendranath Basu gave us of it in his admirable paper some two years ago must still, I am sure, be present to the mind of many of those who are doing me the honour of listening to me now.

Traditional usages, or Smriti were ultimately embodied in codes of law, of which the most famous is that of Manu; and though disfigured by many social servitudes repugnant to the Western mind, they represent a lofty standard of morality based upon a conception of duty, or Dharma, narrowly circumscribed, but solid and practical. Though these codes of law, and notably that of Manu in the form in which we possess them, are of uncertain but probably much later date, they afford us, in conjunction with the vast body of earlier religious and philosophic literature and with a certain amount of scientific literature dealing with astronomy and astrology, with mathematics and specially with geometry, and with grammar and prosody, sufficient materials for appraising, with a fair

measure of accuracy, the stage of progress which the Aryan Hindus had reached in the sixth century, B.C. When the world was young, and they revelled in their recent conquest of a fair portion in it, they delighted to worship the bright gods who had helped them to possess it, and worship and war were the ties that kept their loose tribal organisation together. Out of the primitive conditions of nomadic and pastoral life under the leadership of tribal elders who were both priests and warriors, they gradually passed, after many vicissitudes of peace and war, into more settled forms of agricultural life and developed into distinct and separate polities of varying vitality, but still united by the bond of common religious and social institutions in the face of the indigenous populations whom they drove before them, or reduced into subjection and slowly assimilated as they moved down towards and into the Gangetic plain. As the conditions of life grew more complex, with increasing prosperity and probably longer intervals of peace, differentiation between classes and professions grew more marked. There was time and leisure for thinking as well as for fighting, for contemplation as well as for action. The "bright" gods that Nature had conceived for the early Aryans were fashioned and re-fashioned by speculations already laden with the gloom of melancholy and awesomeness that pervades India. Caste, it may be inferred from the Sanskrit word Varna, which means colour, originally discriminated only between the Aryan conquerors of relatively fair complexion and the darker aborigines they had subdued. It was extended to connote the various stratifications into which Hindu society was settling, and in the stringent rules which governed the constitution of each caste, and the relations between the different castes, the old exclusiveness of tribal customs was perpetuated and intensified.

To the supremacy which the Brahman, as the expounder of the scriptures and of the laws deduced from them, and the ordained dispenser of divine favour, through prayer and sacrifice, was able to arrogate to his own caste, the code of Manu, above all others, bears emphatic witness:

"The very birth of Brahmans is a constant incarnation of Dharma. . . . When a Brahman springs to light he is born above the world, the chief of all creatures, assigned to guard the treasury of duties, religious and civil. Whatever exists in the world is all in effect, though not in form, the wealth of the Brahman, since the Brahman is entitled to it all by his primogeniture and eminence of birth."

Every offence committed by a Brahman involves a relatively slight penalty; every offence committed against him the direst punishment. Next to the Brahman, but far beneath him, is the Kshatria and beneath him again the Vaishyan. The Shudras are the servile caste that exists only to serve the twice-born castes, and above all the Brahman. As Sir William Jones has well said in the preface to the translation which he was the first to make a little more than a century ago of these extraordinarily full and detailed ordinances, they represent a system of combined despotism and priestcraft, both indeed limited by law, but artfully conspiring to give mutual support with mutual checks. But though they abound with minute and childish formalities, though they prescribe ceremonies often ridiculous, though the punishments they enact are partial and fanciful, for some crimes dreadfully cruel, for others reprehensibly slight, though the very morals they lay down, rigid enough on the whole, are in one or two instances, as in the case of light oaths and of pious perjury, dangerously relaxed, one must, nevertheless, admit that, subject to those grave limitations, a spirit of sublime devotion, of benevolence to mankind, and of amiable tenderness to all sentient creatures pervades the whole work, and the style of it has a certain austere majesty that sounds like the language of legislation and extorts a respectful awe. Above all it is well to remember that the ordinances of Manu still constitute to-day the framework of Hindu society, and Brahman judges of the Indian High Courts, who administer our own very different codes, still cling to them in private life and quote them in political controversies as the repositories of inspired wisdom.

It is on this background of tangled religious beliefs and abstruse philosophic speculations and very precise and elaborate laws framed to safeguard the twofold authority of priests and kings, but of the latter always in subordination to the former, that we see a number of small states, amongst which Magadha and Kosala vie for pre-eminence, first assuming historic substance in the sixth century B.C. on the eve of the first great revolt against the whole religious and social system of which I have sought to outline the long and laborious evolution through prehistoric centuries. From that date onwards we shall be on firmer ground. For though, even in much later times, the Hindus have never produced historians in the strict sense of the term, we are

able to call in aid the valuable testimony not only of a few indigenous chronicles, but also of Greek and Chinese and Arab writers and travellers, as well as the authoritative evidence supplied by epigraphy and numismatics; and, though for many centuries still very infrequently, the precious remains of ancient monuments. There will still be many gaps which modern research has so far failed to fill in, but there are henceforth a succession of conspicuous landmarks to show the way; and it is with the help of those landmarks that I propose to follow the rise and fall of Buddhism, than which, I think, no more striking illustration can be found of the marvellous tenacity of Hinduism.

Of these great landmarks, Rajagriha, the King's House, built or rebuilt by King Bimbisara, the fifth monarch of the Saisunaga dynasty of Magadha, appears to be the oldest of which any remains still exist. It lay about forty miles S.S.E. of the modern Patna, and rather less than that N.E. of Buddh Gaya, and the Mahabharata mentions all the five hills which, as the first Chinese pilgrim, Fa-Hien, puts it, "encompass it with a girdle like the walls of a town." It was itself a walled city, and some of the walls, as we can still see them to-day, represent most probably the earliest structure raised in India by human hands that has survived down to our own times. They were no jerry-builders then. Strengthened at sundry points by great square bastions, the walls of Rajagriha measure in places over seventeen feet in width and eleven or twelve feet in height, and they are faced with undressed stones three to five feet in length, without mortar or cement, but carefully fitted and banded together with a core of smaller blocks not less carefully laid and packed. They merely supplemented and completed the natural line of defences provided by the outer girdle of hills, rising to 1,200 feet, which shut off Rajagriha from the plain of Bihar. I visited Rajagriha about fifteen years ago as the guest of Sir John Marshall, the Director-General of Archæology, who was then exploring the long since deserted site, and on one of those peerless days of the cold season in Upper India when there is not a cloud to break the serenity of the deep blue sky, I looked up to the mountain Ghridrakuta, on whose slopes Buddha dwelt for some time after he had found enlightenment at Buddh Gaya, and saw it just as the second Chinese pilgrim to whom we owe most of our knowledge of Rajagriha described it—"a solitary peak rising to a great height on which vultures make their abode." Many had been the revolutions of the wheel of time since Hiuen-Tsang had watched the circling of the vultures round the sacred peak some twelve and a half centuries before me, and as Buddha himself, another twelve and a half centuries earlier, had watched them when he miraculously stretched forth his hand through a great rock to rescue his beloved disciple Ananda from the clutch of the demon Mara, who had taken on the shape of a vulture. The swoop of those great birds seemed to invest the whole scene with a new and living reality. Across the intervening centuries I could follow King Bimbisara proceeding along the causeway of rough, undressed stones, which can be traced to-day to the foot of the mountain and up its rocky flanks, after his men had "levelled the valley and spanned the precipices, and with the stones had made a staircase about ten paces wide," so that he should himself be carried up to wait in his own royal person on the Lord Buddha. There, marked to the present day by the remains of two large stupas, was the place where the king alighted from his litter to go forward on foot, and further up again the spot where he dismissed his followers and went on alone to invite the Buddha to come down and dwell in his capital.

That must have been about 500 B.C., and Buddha spent thereafter a considerable portion of his time in the bamboo garden which King Bimbisara presented to him on the outskirts of Rajagriha. There, and in his annual wanderings through the country, he delivered to the poor and to the rich, to the Brahman and to the sinner, to princes and peasants, to women as well as to men, his message of spiritual and social deliverance from the thraldom of the flesh and from the tyranny of caste.

With the actual doctrines of Buddhism I do not propose to deal. There is nothing in them that could not be reconciled with those of the Vedanta, and they are especially closely akin to the Sankhya system. But the distinctive feature of Buddhism, as also of Jainism, which grew up at the same time as Buddhism under the inspiration of another great reformer, Mahavira, who is said to have been a cousin of King Bimbisara, is the social catholicity of its appeal to all classes and castes, and to women as well as to men. The Vedanta reserved the study of the scriptures to men of the three twice-born castes, and placed it under the supreme authority of the Brahmans. Both Buddha and Mahavira recognised no such restrictions, though they did not refuse reverence to the Brahman as a man of special learning. The religious orders which they founded were

open to all, and these orders included nuns as well as monks. This was the rock on which they split with Hinduism. This was the social revolution that, in spite of the religious and philosophical elasticity of the Vedanta, made Buddhists and Jains unpardonable heretics in the eyes of the Brahmans, and produced a conflict which was to last for centuries.

Though King Bimbisara welcomed the Buddha to his capital, and Buddhism made rapid headway amongst the masses, he does not appear to have himself embraced the new religion, and it is not till after Alexander the Great's expedition had for the first time brought an European conqueror on to Indian soil, and the Mauryan dynasty had succeeded that of Saisunaga and transferred the seat of government to Pataliputra, the modern Patna, on the Ganges, that perhaps the greatest of Indian rulers, the Emperor Asoka, who reigned from 272 to *circa* 232 B.C., made Buddhism the state religion of his Empire. Tradition has it, that when Buddha on his last wanderings passed by the fort which King Ajatasatni was building at Pataliputra, he prophesied for it a great and glorious future. It had already fulfilled that prophecy when the Greek Ambassador, Megasthenes, visited it in 303 B.C. Of that second great landmark in Indian history, a few remains are being laboriously rescued from the waters of the Ganges, under which Pataliputra is for the most part buried. But at that time it spread for ten miles along the river front; five hundred and seventy towers crowned its walls, which were pierced by sixty-four gates, and the total circumference of the city was twenty-four miles. The palace rivalled those of the Kings of Persia, and a striking topographical similarity has been lately traced between the artificial features of the layout of Pataliputra and the natural features of Persepolis, King Darius's capital in Southern Persia.

Pataliputra became the capital of India under Chandragupta Maurya, who, soldier of fortune and usurper that he was, transformed the small kingdom of Magadha into a mighty empire. Known to Greek historians as Sandrokottos, young Chandragupta had been in Alexander's camp on the Indus, and had even, it is said, offered his services to the Macedonian king. In the confusion which followed Alexander's death, he had raised an army with which he fell on the Macedonian frontier garrisons, and then, flushed with victory, turned upon the King of Magadha, whom he dethroned. After eighteen years of constant fighting he had extended his frontiers to the Hindu Kush in the north, and nearly down to the latitude of Madras in the south. He had, at the same time, established a remarkable system of both civil and military administration by which he was able to consolidate his vast conquests. His war office was scientifically divided into six boards for maintaining and supplying his huge fighting force of 600,000 infantry, 30,000 cavalry, 9,000 elephants, and 8,000 war chariots, besides fully equipped transport and commissariat services. No less scientific was the system of civil government as illustrated by the municipal institutions of Pataliputra. There, again, there were six boards dealing respectively with trade, industries, wages, local taxation, the control of foreign residents and visitors, and, perhaps most extraordinary of all, with vital statistics. Equally admirable was the solicitude displayed for agriculture, then, as now, the greatest of Indian industries, and for its handmaid, irrigation. The people themselves, if we may believe Megasthenes, were a model people well worthy of a model government, though if he does not exaggerate, one is driven to wonder at the necessity for such fearful penalties as were inflicted for the most trivial breaches of the law. But behind Chandragupta the power of the Brahman was still clearly entrenched, for his chief minister was a Brahman, Chanakya, who had followed his fortunes from their first adventurous beginnings.

The stately fabric which Chandragupta built up during his own twenty-five years' reign, *circa* 322–297 B.C., endured during the reign of his son Bendusara, of whom scarcely anything is known, and at the end of another twenty-five years passed on, undiminished, to his great successor, Asoka, whose unique experiment would have been scarcely possible had he not succeeded to an empire already firmly consolidated at home and abroad. When he came to the throne, about 272 B.C., Asoka had served his apprenticeship in the art of government as viceroy, first in the north at Taxila, and then in the west at Ujjain. He had been brought up by Brahmans in the manner befitting his rank. Buddhist tradition would have us believe that until his conversion he was a monster of cruelty; but there is scarcely enough to warrant that indictment in the fact that he began his reign with a war of aggression, for which he afterwards expressed the deepest remorse. It was, indeed, from that moment that he determined to be henceforth a prince of peace; but it is quite as probable that his determination inclined him

more and more to turn his ear to Buddhist teaching as that Buddhist teaching prompted his determination.

No monarch has ever recorded the laws which he gave to his people in such imperishable shape. They are to be seen to the present day cut into granite pillars or chiselled into the face of the living rock in almost every part of what was then the Empire of the Mauryas, from the Peshawar district in the north to Mysore and the Madras Presidency in the south, from the Kathiawar Peninsula in the west to the Bay of Bengal in the east. The pillars are often at the same time monuments of artistic design and workmanship, as, above all, the Garnath pillar near Benares with its magnificent capital of the well-known Persepolitan type and its four lions supporting the stone Wheel of the Law, first promulgated on that spot. Many more of Asoka's monuments may yet be discovered, but the eleven pillar edicts and the fourteen rock edicts, not to speak of minor inscriptions already brought to light and deciphered, constitute a body of laws which well deserve to have been made thus imperishable. For no temporal sovereign has ever legislated so fully and exclusively and with such evident conviction for the spiritual advancement and moral elevation of his people. Scarcely less important is the autobiographical value of these inscriptions, which enable one to follow stage by stage the evolution of the Apostle-Emperor's soul. Within a year of the conquest of the Kalinjas, for which he afterwards publicly recorded his remorse, Asoka became a lay disciple of the Buddhist law, and two and a half years later studied as a Buddhist monk. In 257 B.C., the thirteenth year of his reign, he began to preach his series of sermons in stone—sermons that were at the same time laws given to his Empire. His profession of faith was as lofty as it was simple :—

"The gods who were regarded as true all over India have been shown to be untrue. For the fruit of exertion is not to be attained by a great man only, because even by the small man who chooses to exert himself immense heavenly bliss may be won. . . . Father and mother must be hearkened to. Similarly, respect for living creatures must be firmly established. Truth must be spoken. These are the virtues of the law of piety which must be practised. . . . In it are included proper treatment of slaves and servants, honour to teachers, gentleness towards living creatures, and liberality towards ascetics and Brahmans. . . . All men are my children, and just as I desire for my children that they may enjoy every kind of prosperity and happiness in both this world and the next, so I desire the same for all men."

These principles are applied in all the instructions to his officials. He commends to their special care the primitive jungle folk and the untamed people of the borderlands. He bestows much thought on the alleviation of human suffering, and his injunctions in restriction of the slaughter and maiming of animals and the preservation of life are minute and precise. It is in this connection that the influence of Buddhism on Hinduism was most permanent, for whilst the primitive Aryan Hindus were beef eaters, their descendants carried the vegetarian doctrines of Buddhism to the extreme length of condemning cow-killing as the most awful of crimes, next to the killing of a Brahman.

Determined to preserve the unity and discipline of his own church, Asoka's large tolerance sees some good in all creeds. He wishes every man to have the reading of his own scriptures, and whilst reserving his most lavish gifts for Buddhist shrines and monasteries, he does not deny his benefactions to Brahmans and ascetics of other sects. Nor is he content merely to preach and issue orders. His monastic vows, though they lead him to forswear the amusements and even the field sports which had been his youthful pastimes, do not involve the severance of all worldly ties. He is the indefatigable and supreme head of the Church; he visits in solemn pilgrimage all the holy places hallowed by the memory of Buddha, and endows shrines and monasteries and convents with princely munificence; he convenes at Pataliputra a great Buddhist council for combating heresy. But he remains the indefatigable and supreme head of the State. "I am never fully satisfied with my efforts and my dispatch of business. Work I must for the welfare of all, and the root of the matter is in effort." He controls a highly-trained bureaucracy not unlike that of British India to-day, and his system of government is wonderfully effective so long as it is informed by his untiring energy and singular loftiness of purpose.

With Asoka Buddhism attained to a supremacy in India which may well be compared with that of Christianity in Europe under Constantine; and it is only, I think, by measuring the height to which Buddhism had then risen that we can realise the enduring power of Hinduism, as we see it through suc-

cessive centuries slowly and steadily but relentlessly recovering all the ground it had lost until Buddhism at last disappears almost entirely off the face of India, whereas it continued to spread, though often in very debased forms, over the greater part of Eastern Asia, and still maintains its hold there over more than a third of the total population of the globe.

As with most of the great rulers and conquerors that India has from time to time thrown up, Asoka's life-work fell to pieces almost as soon as he had passed away. Not only did the temporal empire which he built up disintegrate rapidly in the hands of his feeble successors, but Buddhism itself was dethroned within fifty years with the last of his dynasty, slain by the usurper Pushyamitra Sunga, who, after consecrating himself to the Hindu gods with the rites of Rajasuya, celebrated his advent to paramount power by reviving the ancient ceremony of Asvamedha, the sacrifice of the horse—one of the most characteristic of Brahmanical rites.

When we reach our next landmark at Purushpura, which became in the first century of our era the capital, situated close to the modern Peshawar, of a new dynasty of Kushan conquerors from Central Asia, we indeed find the greatest of them, Kanishka, shedding a transient gleam of glory over the decline of Buddhism, but of a Buddhism already far removed from the purity of Asoka's reign. The most striking feature of this short-lived revival of Buddhism, is the artistic inspiration which it derived from Hellenistic sources, of which the museums of Peshawar and Lahore contain so many remarkable illustrations. The idea, at one time very widely entertained, that Alexander's meteoric appearance in India left any permanent mark on Indian civilisation, is now entirely discarded by the best authorities. No Indian author makes even the faintest allusion to him, nor is there any trace of Hellenic influence in the evolution of Indian society, or in the elaborate institutions with which India was endowed by the Mauryan dynasty that followed immediately on the disruption of Alexander's empire. But the Kushans, or Yueh Chis, who, during the various stages of their slow migration down into Northern India, came into long and close contact with the Indo-Bactrian and Indo-Parthian kingdoms, carved out of Alexander's dominions. The populations were never Hellenized, but their rulers were to some extent the heirs, albeit hybrid heirs, to Greek civilisation. They spoke Greek and worshipped at Greek shrines, and as they were in turn subjugated by the forbears of the Kushan Empire, they imparted to the victors something of their own Greek veneer. In the second century of our era, Kanishka carried his victorious arms down to the Gangetic plain, where Bhuddism still held its own in the region which had been its cradle; and, according to one tradition, he carried off from Pataliputra a famous Buddhist saint, who converted him to Buddhism. But as these Indo-Scythian kings had not been long enough in India to secure admission to the social aristocracy of Hinduism by that slow process of naturalisation to which so many ruling races have owed their Kshatrya pedigrees, Kanishka, having himself no claim to caste, may well have preferred for reasons of state to favour Buddhism as a creed fundamentally opposed to caste distinctions. Whatever the motives of his conversion, we have it on the authority of Hiuen-Tsang, that he ultimately did great things for Buddhism, and the magnificent stupa, which he erected outside his capital, five and twenty stories high and crowned with a cupola of diamonds, was still 150 feet high and measured a quarter of a mile in circumference when the Chinese pilgrim visited Purushpura five centuries later. To the present day there are traces outside the northern gate of Peshawar of a great Buddhist monastery, also built by Kanishka, which remained a seat of Buddhist learning until it was destroyed by Mohammedan invaders, and it was only a mile from Peshawar that the American Sanskritist, Dr. Spooner, discovered ten years ago the casket containing some of Buddha's bones, which is one of the most perfect specimens of Græco-Buddhist art. The Buddhist statues and bas-reliefs of that period are Greek rather than Indian in their treatment of sacred history, and even the head of Gautama himself might sometimes be taken almost for that of a young Greek god.

These exotic influences may indeed have acted as a further solvent upon Buddhism. But in any case, its local and temporary revival as a dominant state religion under Kanishka, whose empire did not long outlive him, failed to arrest its steady resorption into Hinduism. On the one hand Buddhism itself was losing much of its original purity. The miraculous legends with which the life of Buddha was gradually invested, the almost idolatrous worship paid to him, the belief that he himself was but the last of many incarnations in which the Buddha had already revealed himself from the very beginning of creation—all these later

accretions represent, no doubt, the reaction upon Buddhism of its Hinduistic surroundings. But they doubtless helped also to stimulate the growth of the more definite forms of anthropomorphism which characterised the development of Hinduism when the ancient ritual and the more impersonal gods of the Vedas and of the Brahmanas gave way to the cult of such very personal gods as Shiva and Vishnu, with their feminine counterparts, Kali and Lakshmi, and ultimately to the evolution of still more popular deities, some, like Skanda and the elephant-headed Ganesh, closely connected with Shiva; others like Krishna and Rama, *avātaras* or incarnations—and in many ways extremely human incarnations—of Vishnu. At the same time, the Aryan Hindus, as they came to subdue the numerous aboriginal races of India, constantly facilitated their assimilation by the more or less direct adoption of their primitive deities and religious customs. The two great epics, the Mahabharata, with its wonderful episode, the Baghavad-Ghita, which is the apotheosis of Krishna, and the Ramayana, which tells the story of Rama, show the infusion into Hinduism of a distinctly national spirit in direct opposition to the almost international catholicity to which Buddhism owes the facility with which it adapted itself to the political aspirations of non-Hindu conquerors as well as of non-Hindu races beyond the borders of Hindustan, in Nepal and in Ceylon, in Burma and in Tibet, in China and in Japan. Thus the conflict between Buddhist and Hindu theology might not have been irreconcilable, for Hinduism, as we know, was quite ready to admit Buddha himself into the privileged circle of its own gods as one of the avatars of Vishnu. What was irreconcilable was the conflict between a social system based on Brahmanical supremacy and one that denied it—especially when Hinduism introduced into it an element of nationalism. It is, therefore, not surprising to find this element conspicuous when from another long period of darkness which followed the downfall of the Kushan kingdom, Indian history emerges into the splendour of what has been called "the golden age of Hinduism" in the fourth and fifth centuries of our era under the great Gupta dynasty, who ruled at Ujjain.

Few Indian cities are reputed to be more ancient or more sacred than the little town of Ujjain on the Sipra river, known as Ozenī to the Greeks, and where Asoka had ruled in his youth as Viceroy of Western India. It owes its birth to the gods themselves. When Uma wedded Shiva, her father slighted him, not knowing who he was, for the mighty god had wooed and won her under the disguise of a mere ascetic mendicant, and she made atonement by casting herself into the sacrificial fire, which consumed her, the prototype of all pious Hindu widows who perform Sati, in the presence of gods and Brahmans. Shiva, maddened with grief, gathered up the bones of his unfortunate consort and danced about with them in a world-shaking frenzy. Her scattered bones fell to earth, and wherever they fell, the spot became sacred and a temple sprang up in her honour. One of her elbows fell on the banks of the Sipra at Ujjain, and few shrines enjoy greater or more wide-spread fame than the great temple of Maha-Kal, consecrated to her worship and that of Shiva. Its wealth was fabulous when it was looted and destroyed by Altamsh and his Pathan Mohammedans in 1235. The present buildings are for the most part barely 200 years old, and remarkable chiefly for the insistency with which the lingam and the bull, the favourite symbols of Shiva, repeat themselves in shrine after shrine. But it attracts immense numbers of pilgrims, especially in every twelfth year, when they flock in hundreds of thousands to Ujjain and camp as near as possible to the river. The peculiarity of the Ujjain festival is that, in memory of the form which Shiva took on when he wooed Uma, it attracts a veritable army of Sanyasis, or mendicants, sometimes as many as fifty thousand, from all parts of India. Seldom, except at the great Jaganath festivals at Puri, is a larger congregation seen of weird and almost inhuman figures, some clothed solely with their long, unkempt hair, some with their bodies smeared all over with white ashes and the symbol of their favourite deity painted conspicuously on their foreheads, some displaying ugly sores or withered limbs as evidence of lifelong mortification of the flesh, some moving as if in a dream and entirely lost to the world's realities; some with frenzied eyes shouting and brandishing their instruments of self-torture, some with a repulsive leer and heavy, sensuous jowls affecting a certain coquetry in the ritualistic adornment of their well-fed bodies.

Chandragupta I., the founder of the great dynasty which Hindus extol over all others, was only a petty chieftain by birth, but he was fortunate enough to wed a lady of high lineage, who could trace a connection with the ancient Maurya house of Magadha, and, thanks to this alliance and to his own prowess, he was able at his death to bequeath real kingship to his son,

Samadragupta, who, during a fifty years' reign, 326–375 A.D., again welded almost the whole of India north of the Nerbudda river into one empire, and once even spoiled Southern India right down to Cape Comorin. His victories are recorded—with an irony perhaps not wholly accidental—beneath the Asokan inscription on the Allahabad pillar. Of his zeal for Hinduism we have a convincing proof in gold coins of his reign that preserve on the obverse in the figure of the sacrificial horse a record of the Asvamedha, which he again revived. Strange to say, however, his fame has never been so popular as that of his son, Chandragupta II., Vikramadytia, the Sun of Power, who reigned in turn for nearly forty years, and has lived in Hindu legend as the Raja Bikram, to whom India owes her golden age. It was his court at Ujjain which is believed to have been adorned by the "Nine Gems" of Sanskrit literature, amongst whom the favourite is Kalidasa, the poet and dramatist. Amidst much that is speculative, one thing is certain. The age of Vikramadytia was an age of Brahmanical ascendancy. As has so often happened, and is still happening in India to-day in the struggle between Urdu and Hindi, the battle of religious and political supremacy was largely one of language. During the centuries of Brahmanical depression that preceded the Gupta dynasty, the more vulgar tongue spoken of the people prevailed. Under the Guptas, Sanskrit, which was the language of the Brahmans, resumed its pre-eminence and took possession of the whole field of literature and art and science as well as of theology. Oral traditions were reduced to writing and poetry was adapted to both sacred and profane uses in the Puranas, in the metrical code of Manu, in treatises on sacrificial ritual, in Kalidasa's plays, and in many other works of which only fragments have survived. Astronomy, logic, philosophy, were all cultivated with equal fervour and to the greater glory of Brahmanism. Local tradition is doubtless quite wrong in assigning to Raja Bikram the noble gateway which is the only monument of Hindu architecture at its best that Ujjain has to show to-day. But to that period may, perhaps, be traced the graceful, if highly ornate, style of architecture, of which the Bhuvaneshwar temples, several centuries more recent, are the earliest examples that can be at all accurately dated. To the credit of Brahmanism be it said that in its hour of triumph it remained at least negatively tolerant, as all purely Indian creeds generally have been. Fa-Hien, who visited India during the reign of Vikramadytia, though dismayed at the desolation which had already overtaken many of the sacred places of Buddhism, pays a generous tribute to the tolerance and statesmanship of that great sovereign. The country seems, indeed, to have enjoyed considerable prosperity under a paternal and almost model administration.

Yet the Gupta dynasty endured only a little longer than had that of the Mauryas. Its downfall was hastened by the long reign of terror which India went through during the invasion of the White Huns. Europe had undergone a like ordeal nearly a century earlier, for when the Huns began to move out of the steppes of Eastern Asia they poured forth in two separate streams, one of which swept into Eastern Europe, whilst the other flowed more slowly towards Persia and India. What Attila had been to Europe, Mihiragula was to India, and though the domination of the Huns did not long outlive him, the anarchy they left behind them continued for another century, until "the land of Kuru," the cradle and battle-field of so many legendary heroes, produced another heroic figure, who, as King Harsha, filled for more than forty years (606–648) the stage of Indian history with his exploits. He had inherited the blood of the Gupta emperors from his mother, though his father was only a small Raja, of Thanesvar, to the north of Delhi; the tragic circumstances in which he succeeded him made a man of him at the early age of fourteen. By the time he was twenty he was "master of the five Indias"—*i.e.*, of nearly the whole of Northern India from Kathiawar to the delta of the Ganges, and henceforth he proved himself as great in peace as in war. In his case the knowledge we owe to Chinese sources is supplemented by the valuable record left by the Brahman, Bana, who lived at his court and wrote the Harsha-Charita. Taxation, we are told, was lightened and the assessment of land revenue was equitable and moderate. Security for life and property was enforced under severe but effective penalties. Education received impartial encouragement whether conducted by Brahmans or by Buddhist monks, and both as a patron of literature, which he himself cultivated by composing dramas, and as a philanthropic ruler, King Harsha bestowed his favours with a fairly equal hand on Hinduism and on Buddhism alike. For Buddhism still lingered in the land, and Harsha, who was a mystic and a dreamer, as well as a man of action, certainly inclined during his later years towards Buddhism,

or, at least, included it in his own eclectic creed.

Hiuen-Tsang, who spent fifteen years in India during Harsha's reign, searching for the relics of early Buddhism in a land from which it was steadily disappearing, has given us a wonderful picture of a religious state-pageant which makes Prayaga, at the triple confluence of the Ganges and the Jumna with the sacred but invisible river, Saraswati, near to the modern city of Allahabad, stand out as another striking landmark in Indian history. Hindus attach great holiness to rivers and their confluence, and this Triveni, or triple confluence, had been specially consecrated by Brahma, who chose that spot for the first Asvamedha. "From ancient times," says the Chinese chronicler, "the kings used to go there to distribute alms, and hence it was known as the Place of Almsgiving. According to tradition more merit is gained by giving one piece of money there than one hundred thousand elsewhere." So King Harsha, having invited all alike, whether "followers of the law or heretics, the ascetics and the poor, the orphans and the helpless," the kings of eighteen subordinate kingdoms assembled there with their people to the number of 500,000, and found immense refectories laid out for their refreshment and long rows of warehouses to receive silk and cotton garments and gold and silver coins for distribution to them. "The first day a statue of Buddha was placed in the shrine erected on the Place of Almsgiving, and there was a distribution of the most precious things and of the garments of greatest value, whilst exquisite viands were served and flowers scattered to the sound of harmonious music. Then all retired to their resting-places. On the second day a statue of the Sun-god was placed in the shrine, and on the third day the statue of Shiva," and the distribution of gifts continued on those days and day after day for a period of over two months, ten thousand Brahmans receiving the lion's share, until, having exhausted all his wealth, even to the jewels and garments he was wearing, King Harsha borrowed a coarse and much-worn garment, and having "adored the Buddhas of the ten countries," he gave vent to his pious delight, exclaiming: "Whilst I was amassing all this wealth I was always afraid lest I should find no safe and secret place to stow it away. Now that I have deposited it by almsgiving in the Field of Happiness I know that it is for ever in safety. I pray that in my future lives I may amass in like manner great treasures and give them away in alms so as to obtain the ten divine faculties in all their plenitude."

Here one sees India as it was before the Mohammedan invasions, in the days of the last of the great Indian rulers who succeeded for a time in bending the whole of Northern India to his will. As always in India, behind whatever form of temporal power may for the moment appear to be paramount, religion and the social order which it consecrates, represent the real paramount power that alone endures. In this extraordinary festival which marked the close of Harsha's reign the picture left to us is singularly complete. The first day is a sort of farewell tribute to the waning glory of Buddha, and the second to the ancient majesty of the Vedic gods; but they only prepare the way for the culminating worship, on the third day, of the terrific figure of Shiva, who had already been raised to one of the highest, if not the highest, throne in the Hindu pantheon, which he still retains—Shiva, the master of life and death, whose favourite emblem is the phallus, and from whose third eye bursts forth the flame which is one day to consume the world. Around him are the Brahmans and the ascetics, who devour the gifts of Harsha until, at the end of two months, they are wholly exhausted, just as they continue to the present time to live on the gifts of the Hindu peoples, and through them indirectly on the gifts of the British *raj*, which has secured to the Hindu peoples a measure of prosperity they never enjoyed in the days even of King Harsha.

Shortly after Harsha's death in 648 A.D., India, as is her wont as soon as the strong man's arm is paralysed, relapses once more into political chaos. Her history does not indeed ever again recede into the complete obscurity of earlier ages. We get glimpses of successive kingdoms and dynasties rising and again falling in Southern India, as the Hindu Aryans gradually permeate and subdue the older Dravidian races and absorb the greater part of them, not without being in turn influenced by them, into their own religious and social system. Time does not allow me to follow their growth and their decline. I will only mention that it was in the south of India that the last great Hindu kingdom, that of Vijayanagar, whose splendid ruins still line the banks of the Tungabhadra River, in the Bellary district of the Madras Presidency, survived until the middle of the sixteenth century, when it fell at Talikot (January 23rd, 1565) before the fierce onrush of Islam. But the flowing tide of Islam spent itself on that

stricken field, and as Southern India never remained so completely under the heel of the Mohammedan conquerors, it is there that we still have to look for the most imposing monuments of Hindu architecture and for the most characteristic manifestations of Brahmanical supremacy in Hindu society. But I must pass them by, as it is not in Southern India that the enduring power of Hinduism has ever been subjected to the supreme tests which it has undergone in the north.

It was during Harsha's reign that militant Islam first set foot in India, in a remote part of the peninsula. Just at the same time as the Arabs, in the first flush of victory, poured into Egypt, a small force crossed the Arabian Sea and entered Baluchistan, and a century later the whole of Sind passed into Arab hands. But those happenings were too distant to produce more than a local impression, and the most notable feature of the post-Harsha period is the emergence of the Rajput states, whose rulers, though probably descendants of relatively recent invaders, not only became rapidly Hinduised, but secured relatively prompt admission to the rank of Kshatryas in the Hindu caste system, with pedigrees dated back to the Sun and Moon, which to the popular mind were well justified by their warlike prowess and splendid chivalry. I need only recall the name of Prithvi-Raja, the lord of Sambhar, Delhi, and Ajmer, whose epic fame rests not less on his abduction of the Kanauj princess who loved him than on his gallant losing fight against the Mohammedan invaders. By that time, *i.e.*, by the end of the twelfth century, the Mohammedan flood was pouring irresistibly into India, no longer across the Arabian Sea, but from Central Asia through the great northern passes. The first irruption under Mahmud Ghasni, in the year 1002, had been merely the precursor of the more formidable invasions which were to follow in quick succession, until Sultan Baber completed the conquest of Hindustan and founded the Moghul Empire in the early part of the sixteenth century, out of the ruins of which the British Empire of India was in turn to grow up.

Now if we look back upon the fifteen centuries of Indian history, before the great Mohammedan invasions, of which I have tried to reconstitute the chief landmarks, the two salient features that seem to me to emerge from the twilight, are the failure of the Aryan Hindus to achieve any permanent form of political unity or stability and their success, on the other hand, in building up on adamantine foundations a complex but vital social system. The Mauryan and the Gupta dynasties succumbed as irretrievably to the centrifugal forces of petty states and clans perpetually warring against one another, as the more ephemeral kingdoms of Kanishka and Harsha. Buddhism, in spite of its tremendous uplift in the days of Asoka and the intermittent favours it enjoyed under later and lesser monarchs, was already moribund in India before the Mohammedans gave it its final death-blow. Jainism, contemporary with and closely akin to Buddhism, never rose to the same pre-eminence, and perhaps for that very reason secured a longer though more obscure lease of life, and still survives as a respectable but numerically quite unimportant sect. The supple and subtle forces of Hinduism alone welded together the discordant beliefs and customs of a vast variety of races into a comprehensive fabric sufficiently elastic to shelter most of the indigenous populations of India, and sufficiently rigid to secure Aryan Hindu ascendancy.

In conclusion, I will merely point out briefly how the same process of adaptation, assimilation and absorption, which had been going on for centuries before the Mohammedan conquest, without ever being permanently or even very deeply affected by the vicissitudes of Indian political history, has gone on ever since in spite of seven centuries of alien domination. Whilst millions of Hindus were, it is true, being forcibly converted to Islam, Hinduism, making good its losses to a great extent by the complete elimination of Buddhism, and by permeating the Dravidian races of Southern India, continued its own social and religious evolution. It was, indeed, after the tide of Mohammedan conquest had set in that the rivalry between the cults of Shiva and of Vishnu became most acute, and many of the Dharmashastras and Puranas were recast and elaborated by Shivaite and Vishnuite writers respectively, in the form in which we now know them, and thus afford interesting pictures of the persistency of Hindu life and manners after India had lost all political independence. It was then, too, that Krishna rose to be perhaps the most popular of Hindu gods, and the divine love of which he was at first the personification, was to a great extent lost sight of in favour of his human amours, and that the works known as the Tantras, deriving in their origin from the ancient ideas of sexual dualism immanent in some of the Vedic deities, developed the customary homage paid to the consorts of the great gods into the Sakti worship of the female principle, often with ritual

observances either obscene or sanguinary, or both. Possibly as a result of closer contact with primitive Dravidian religions, the blood even of human victims flowed more freely before the altars of the Mahamatri, the great goddesses personified in Kati and Durga. Sati, *i.e.*, the sacrifice of Hindu widows on the funeral pyres of their husbands, was more frequently practised. Many of the most splendid and, at the present day, most famous temples—amongst others, that of Jaganath at Puri—were founded during that period, when also the practice, in itself very ancient, of religious pilgrimages to celebrated shrines, and to the banks and sources of specially sacred rivers, was laid down in elaborate manuals which became text-books of ritual as well as of religious geography. Much of what might be regarded as the degeneration of Hinduism from its earlier and more spiritual forms into gross idolatry and licentiousness, may well have been in itself a reaction against the stern monotheism of the politically triumphant Mohammedans. Caste, which was as alien to Islam as to Christianity, but nevertheless asserted its influence upon Indian Mohammedans, as it has also upon the later Indian converts to the Christian creeds, tended to harden, and developed into the infinite complexity of castes and subcastes, thousands in number, which are determined sometimes by their occupation, sometimes by ethnological distinctions, sometimes by historical considerations, but which irrevocably govern by the mere accident of birth the whole course of a Hindu's social and domestic relations, and how throughout life he shall eat, drink, dress, marry, and be given in marriage, and ultimately be helped to rebirth in another life.

The most permanent, or at least the most signal, mark which Mohammedan domination has left upon Hinduism has been to accentuate the inferiority of woman by her close confinement—of which there are few traces in earlier times—within the zenana, possibly in the first instance a precautionary measure for her protection against the lust of the Mohammedan conquerors. Twice an attempt was made to bridge the gulf between Islam and Hinduism. Akbar, the greatest of the Moghul emperors, not content to woo the Hindus politically by giving them high offices and promoting matrimonial alliances between his own house and the princely families of Rajputana, sought to found a new state religion acceptable to both Hindus and Mohammedans, of which he was himself to be the prophet, but even his genius failed to square that circle.

More lasting, but within very narrow limits, was the gospel of fraternity taught a century earlier by Kabir, who may have been born a Mohammedan, and certainly had strong leanings towards Islam. But his few writings that have survived, and the doctrines held by the small number of adherents who still revere him, show him to have been essentially a reformer in search, like Akbar, but from religious conviction and not on grounds of political expediency, for a unitary form of religion in which both Hindus and Mohammedans could combine against idolatry and caste.

Such also in his early teachings was Nanak, the founder of Sikhism, which developed afterwards into a political movement of revolt against Moghul tyranny, and on the ruins of the Moghul Empire built up a formidable military state in the Punjab, which fell with Ranjit Singh before the growing power of the British *raj*. Under British rule Sikhism reverted to its original character as a religious sect, and still numbers some three million adherents in the Punjab. It is still fundamentally opposed to Hinduism, but the forces of Hinduism are closing in upon it, and the gradual abandonment of Sikh customs and observances by many of the younger Sikhs, their frequent reversion to Hindu rites, the revival of caste divisions amongst them, the willingness of certain classes of Brahmans to attend their domestic festivities, all point to the gradual resorption of Sikhism into the capacious fold of Hinduism by the same processes that slowly stifled or transformed Indian Buddhism out of existence.

The effect of the British domination, which grew up irresistibly and almost unconsciously from the ruins of Mohammedan domination, has been very different. The British never attempted to impose their own creed on the peoples of India. Their policy was from the very first one of the most strict neutrality and tolerance in religious matters, and missionary enterprise: whatever sympathy it may have enjoyed at the hands of British rulers, has been rigorously confined within the limits of such permissible suasion as can be exercised through philanthropic and educational channels. There were small communities of native Christians in India long before the British ever landed there, some dating to the period of Portuguese ascendancy and some to far earlier times. Even to-day the total number of native Christians does not exceed four millions, mostly in Southern India and largely recruited from the lowest castes of Hinduism, or from the very primitive races

which have never been absorbed into Hinduism. Western civilisation has, nevertheless, exercised indirectly a far greater influence on the mind and soul of India than Islam ever did. Three-quarters of a century ago many Englishmen believed that Hinduism would speedily collapse, or at least undergo complete transformation, under the moral pressure of Christian civilisation and Western education. For a time that belief seemed to be justified. In Bengal especially there was a wonderful response to the call of the West. The youth of the higher castes, who had monopolised the ancient learning, monopolised the new schools of Western learning. Even Brahmans embraced Christianity, and many of those who did not were inspired by its ideals to recognise the necessity of far-reaching social and religious reforms. The names of Ram Mohan Roy (the founder of the theistic Brahmo-Somaj), Keshub Chunder Sen, Debendranath Tagore, stand out conspicuously amongst the pioneers of a brilliant and promising movement which directed its attacks in the first place against idol worship as well as against polygamy and child marriage, and many other social evils of Hinduism incompatible with modern progress. The Prarthana-Somaj, of which Mr. Justice Ranade was, perhaps, the best known supporter, represented somewhat later a similar school of Hindu thought in Western India. As far back as 1829 Lord Henry Bentinck carried a large body of enlightened opinion with him in proscribing Sati; later on the Government of India found enough support for various legislative enactments raising the age of consent for the consummation of infant marriages. Caste itself had to relax some of its most irksome restraints in order to meet the material exigencies of modern conditions of life, and notably the promiscuous contact inseparable from new facilities of travel. One might have expected that the importation into India of Western political conceptions, sometimes of an apparently very advanced democratic type, would have given a vigorous impulse to these reform movements. But this has not been altogether the case. The great Mutiny of 1857, on the surface a military and largely Mohammedan revolt, was to a great extent engineered and supported by the reactionary forces of Hinduism, which had begun to realise how gravely their ancient beliefs and customs and their own privileged position were menaced by the growing ascendancy, spiritual as well as material and political, of Western civilisation under the British *raj*. The racial bitterness engendered by the excesses of the Mutiny and its repression, combined with the diffusion of Western education and of English as the great unifying vehicle of Indian thought amongst the diversity of Indian peoples speaking fifty different tongues, tended to revive and fortify as never before the vague national aspirations of which the germs contained in the ancient literature of Hinduism had already once before, as we have seen, stimulated the Brahmanical reaction against Buddhism. The frank acceptance of the all-round superiority of Western civilisation made room for new movements that recognised only its material but not its spiritual superiority, and were ready to adopt its political methods, but mainly for the purpose of emancipating India from a tutelage which, it was alleged, had paralysed her soul. The effect, if not the purpose, of these new movements has been to relegate social and religious reforms to the background, or at least to confine them within limits compatible with the ancient structure of Hinduism. The Prarthana-Somaj is almost forgotten in Bombay, and in Bengal the Brahmo-Somaj, with all its far-reaching influence, has shrunk into such numerical insignificance that barely five thousand still professed their adherence to it at the last census in 1911.

Of the new movements, the Arya-Somaj in the Punjab professes to have found the secret of the spiritual as well as political renascence of India in a return to the purer Vedic doctrines of early Hinduism. Others appeal to the short-lived and largely mythical glories of a past when, under Hindu rulers, India is supposed to have been free and wealthy and wise beyond all nations of the world.

I have no wish to dwell upon the political controversies of the day, but I may be allowed to draw attention to the very significant part which the theology and religious ritual of Hinduism has played in all the recent phases of Indian political agitation. Most of the secret societies which have borrowed their anarchist methods from the West have placed themselves under the special patronage of Kali and other gloomy divinities of the Hindu pantheon. Mr. Tilak, who first entered public life as a bitter opponent, on grounds of Brahmanical orthodoxy, of the 1891 Bill in restraint of infant marriages, owes his wonderful influence on Mahratta audiences to the skill with which he interweaves his political diatribes with quotations from the sacred literature of Hinduism and appeals to the most popular of Hindu divinities. Nor would Mrs. Besant's

gift of eloquence have sufficed to make Hindus almost forget for a time that she was a mere woman, had she not used it to preach the superiority of Hindu philosophy and Hindu learning and Hindu life over anything that the West has ever produced. Mr. Gandhi's dangerous doctrine of passive resistance would never have borne such tragic fruits, had he not possessed the reputation of a Hindu saint. The Hindu prohibition of cow-killing, which is the most frequent source of violent and often sanguinary rioting between the Hindu and Mohammedan masses, is still a formidable obstacle to the effective co-operation of Hindus and Mohammedans in spite of all the efforts made by political leaders on both sides to reconcile their religious differences. In all essentials, and above all in the iron laws which govern intermarriage, the supremacy of caste still remains practically untouched; and as many societies spring up to defend as to attack ancient customs and superstitions which half a century ago few educated Hindus would have cared publicly to uphold. To quote a Hindu writer:—

"The present political agitation, in its initial stages, had a strong leaven of the spirit of Western politics, but at present a clearer consciousness of Aryan, *i.e.*, Hindu greatness, and a strong love and reverence for the Motherland have transformed it into a shape in which the religious element predominates. Politics is a part of religion and it has to be cultivated in an Aryan way, in accordance with the precepts of Aryan religion."

It is this extraordinary blend of extremely Western forms of political activity with the most ancient religious and social conceptions of the East that invests with peculiar interest the operation of the latest ferment which we are about to introduce into the life of India, in response to Indian demands urged by none more loudly than by the protagonists of Hinduism, by setting up representative institutions of the approved democratic type. How that ferment will ultimately work I for one am not prepared to prophesy, but it cannot be without significance that the first effect has been to provoke an immediate revolt against Brahmanical ascendancy amongst the non-Brahman castes of Southern India—*i.e.*, of the very part of India in which, as it was never entirely submerged by the flood of Mohammedan conquest, the caste system has been most fully preserved. The event alone can show whether it represents a new grouping of real and vital forces within Hinduism which will help to shape the social as well as political evolution of India on Western lines, or whether it will in turn succumb to the same process of resorption which has hitherto prevailed over every movement of revolt against the fundamental principles of Hinduism.

To those who hoped for a more rapid fusion of Indian and Western ideals, some of the phenomena which have marked the latter-day revival of Hinduism have brought grave disappointment, but the inrush of Western influences had, perhaps, been too violent not to provoke a strong reaction. It is easy for us to pass judgment on such institutions as caste and Brahmanical ascendancy, and in a paper read only a few years ago before this society by Sir Krishna Govinda Gupta we heard very severe condemnation passed upon them by one of the most distinguished pioneers of enlightened Indian Nationalism. But let us not forget that to those institutions India owes the one great element of stability that has enabled her to weather so many tremendous storms without altogether losing the sense of a great underlying unity stronger and more enduring than all the manifold lines of cleavage which have tended from times immemorial to divide her. Hinduism has not only responded for some forty centuries to the social and religious aspirations of a large and highly endowed portion of the human race, almost wholly shut off until modern times from any intimate contact with our own Western world, but it has been the one great force that has preserved the continuity of Indian life. Could it be expected to yield without a struggle to the new forces, however superior we may consider them and however overwhelming they may ultimately prove, which British rule has imported into India during a period of transition more momentous than any other through which she has ever passed, but still very brief when compared with all those other periods of Indian history which have only recently been rescued from the legendary obscurity of still earlier ages?

THE CHAIRMAN (Lord Meston), said that, as Sir Valentine Chirol had pointed out at the beginning of his lecture, the present was indeed a very remarkable occasion, because it was the first time on which the Society met to commemorate, in a manner especially appropriate to its great traditions, the memory of one who might, without irreverence, be called the tutelar deity of that institution. Most of those present must have known Sir George Birdwood, and to know him was to love him. Personally he knew Sir George

only in his picturesque old age, and he always appeared to him, not as a normal product of the dull Victorian era, but as the reincarnation of some ancient teacher or mediæval wise man, a sort of Galen or Browne come back to earth again. His ripe wisdom, his inexhaustible fund of knowledge, his whimsical humour, and, above all, his irrepressible vitality, made him a unique figure in the intellectual life of his own generation. But even what seemed in him to be the gift of perennial youth was unavailing against the sharp tooth of fate, and so it was that the audience was present that afternoon to commemorate his memory. He was sure everybody would agree that as a high priest for that ceremony no better choice could have been made than that of Sir Valentine Chirol. His mature sagacity, his wide knowledge of men and affairs, and his happy faculty of felicitous diction, of which they had had so striking a proof that afternoon, marked out Sir Valentine as belonging to that family of chosen spirits of which Sir George Birdwood was a member, and they could almost imagine the quip of happy contentment with which Sir George, from the Elysian fields, would send his greetings to the lecturer, and his congratulations on the treatment of a subject which lay so near his heart. After an intellectual treat, such as the audience had had that afternoon, he was sure they would resent the diminution of its effects by any lengthy commentary. In the circumstances, perhaps, the way in which he could best serve those present was by expressing their gratitude to Sir Valentine for what he had taught them that afternoon. He ventured to say that even the most learned present—and there were many learned men and women in that stately chamber—had learned something from what they had heard in the lecture. What struck him most about it, and what he thought it had probably taught the majority of the audience, was the secret of the enduring power of Hinduism. It had always been a puzzle to many of them how Hinduism had endured the fiery tests and trials to which it had been subjected through thousands of years; how it had succeeded in absorbing the great reforming faiths of Buddhism and Jainism, and how it held its own against the fierce proselytising power of Islam. It was possible that the gentle faith of Buddhism was born into the world too soon; it was seven centuries later before our own great Reformer came upon earth. It was also possible that Islam descended upon India too late, for all that it succeeded in doing in reality was to temper, toughen, and consolidate that wonderful complex of social, intellectual, and religious life which constituted Hinduism. That explanation by itself would, however, be misleading and insufficient, because it was impossible to conceive of a religion which had stood the test of those thousands of years, and which still commanded the hearts of hundreds of millions of people unless it had deep and enduring virtues of its own. He thought the audience had gathered from the lecture what some of its more prominent virtues were—its marvellous organisation of family life, its sagacious outlook upon the future of the human race, and its constant stretching-out for contact with the unknown and invisible world. To many minds there had also arisen the problem on which Sir Valentine touched at the end of his lecture, a problem all the more fascinating because none of those present would live to see its solution, namely, the problem of how Hinduism was going to deal with the new powers which now faced it—powers infinitely greater than the reforming vitality of Buddhism, infinitely greater than the martial ruthlessness of Islam—to wit, the growing force of modern democracy. To most Englishmen, it was, he thought, true that there seemed much in the democratic theory which was radically incompatible with the organisation of Hinduism, and it would be one of the most momentous and most attractive processes of the human mind in the future to see the keen, plastic, Brahmin intellect gird itself up to meet and to conquer, or to absorb, the new forces that were now impinging upon it at every point.

THE RT. HON. LORD GEORGE HAMILTON, G.C.S.I., D.C.L., LL.D., proposed: "That the best thanks of this meeting be accorded to Sir Valentine Chirol for his able and interesting lecture." They had, he said, listened with great pleasure to a singularly erudite and comprehensive address, expressed with all the literary finish characterising Sir Valentine Chirol's writings. It was worthy of the occasion and of the distinguished man to whose memory it was dedicated. He took it as a great personal privilege that he had been asked to speak upon it. The matter of the lecture was so voluminous, its retrospect and deductions so far-reaching, that he felt himself quite unable to attempt to analyse or criticise its general purport. But he greatly admired and appreciated the detachment of its tone, its liberality of sentiment, and its tolerance of Asiatic philosophy and doctrines which were, at first sight, antagonistic to accepted European traditions and aims. He desired to concentrate the few words he had to say upon the career, character, and achievements of that notable man, the late Sir George Birdwood. He knew Sir George very well. He (Lord George Hamilton) spent the greater part of his official life at the India Office; he was for five years Under-Secretary of State, and for eight years Secretary of State, and during the whole of that period he was in close personal contact with Sir George, and when out of office his correspondence with him was varied and continuous. Few, if any, Anglo-Indians equalled him in his knowledge of Indian art, industries, and literature, and this encyclopedic mass of information was always at the disposal of his friends. He had also studied very carefully the psychology, past history, and present ambitions of the great races of India, though, from his residence in the West of India, it was to that part of the country that he gave most of his attention. He (Lord George Hamilton) once asked a most

distinguished Anglo-Indian administrator what was the feeling most embedded in his mind about India when, after a lifetime of hard work, he came home to England, and his reply was: "How little I knew of the country and of the inner thoughts of its people." Long as was his official connection with India, though his experience was purely English, he always came back to that opinion. It was not the fault of the Indian or of the Englishman; it arose from the fact that there was a natural chasm between the mentality of the Asiatic and the mentality of the European which few could effectually bridge over. Sir George was one of the few so gifted and so possessed, and he always utilised his knowledge and gifts to help others to achieve the same feat. In speaking of the difference between Asiatic and European minds, it must not for a moment be supposed that he meant that where the difference existed the European was always right and the Asiatic wrong. Behind India there were customs, traditions, and religions immeasurably older than our own. They were to a large extent stabilised and immutable, and the outcome of those influences was always asserting itself, even though the words used might not seem to fit into our polity and acquiesce in our objects. A well-known Anglo-Indian editor once said that Europe could not found a religion, or Asia make a steam-engine. All intellectual religions had Asiatics for their founders; mechanics and the harnessing of the latent forces of nature to purposes of utility were European attributes. So it came to pass that, with the best of intentions, the two mentalities, each excellent, but with limitations, constantly found it difficult to secure that unity of conception and co-operation which a single-minded race could achieve. That was especially the case when reforms and changes based on European ideas were to be transplanted and sown on Indian soil. The words used on both sides might not be the same. The mouth might give utterance to the same phraseology, but the interpretation of what those words conveyed or to what they might lead was at times irreconcilably different. The lecture was entitled "The Enduring Power of Hinduism," and the author gave undeniable and historical evidence of its strength and vitality. The backbone of Hinduism was Brahminism, and caste was the vertebræ of that backbone. There was a struggle for a few centuries between the conflicting tenets of Buddhism and Brahminism. The first religion gained the upper hand, but Brahminism then, as the lecture showed, so asserted itself as to eradicate completely its rival from Indian soil. He did not wish to introduce any contentious element into his speech, but when he heard that a representative government on a popular basis was to be adopted in India, he asked himself, "How can any such form of government exist alongside of the institution of caste?" Again, European ideas of administration were all based upon the supremacy of the majority; but from time immemorial India had been governed by racial minorities, small in numbers compared to those they controlled. Taking the Hindu family system, the devolution and retention of property was governed by the continuous observance of religious duties performed by the living for the edification and honour of the dead. There, again, there was a chasm of divergence between the practices of Hinduism and Christianity. He had a remarkable illustration of that whilst in office. He received a memorial signed by the heads of every Christian community in India protesting against the oppression of Christianised Hindus in the South of India. It was alleged that, in consequence of becoming Christians, they were punished by being deprived of that part of the family property which they would have enjoyed if they had remained Hindus. It was pointed out that in the Royal Proclamation which was issued when India was transferred to the Crown it was laid down that no person was, directly or indirectly, to be penalised on account of his religious tenets, and that what was going on in South India was a flagrant infraction of that principle. The facts alleged were undeniable. The Hindu version was that family life and family property, whether partible or impartible, were governed by the constant performance of religious ceremonies in honour of the dead. If an individual changed his religion, he *ipso facto* was unable to perform these duties, and dropped out of the family life and the laws of inheritance. To do what was asked was to give an apostate Hindu a pecuniary advantage over his orthodox family contrary to Hindu custom. It was putting a premium upon religious apostacy. They accepted the Hindu contention, as it was in accordance with Hindu law, tradition, and the justice of common-sense. He could multiply other instances of the necessity of trying to look at Indian questions from an Asiatic point of view, and of cultivating the attitude in such matters which Sir George Birdwood so consistently maintained. He asked no one to subordinate his sense of right to wrong or to cultivate popularity by the advocacy of impracticable and dangerous experiments. But he implored them to approach all Indian problems, as did Sir George, not in a mood of bias or inherent superiority, but in a spirit of vigilant investigation and receptivity.

SIR HENRY TRUEMAN WOOD, in seconding the motion, said Sir George Birdwood had a very large number of friends, all of whom loved him, but he was not prepared to say they always agreed with the conclusions to which a somewhat impetuous spirit and a rather fantastic imagination sometimes carried him. He did not think, however, anyone could have been associated with Sir George Birdwood without acquiring a sincere affection for him. His friends appreciated his genuine artistic capacity; they recognised the vast extent of his literary and artistic knowledge, to say nothing of his scientific knowledge; and, above all, they admired and appreciated the manner in which he devoted himself to the task of his life—the benefit of the peoples of India, and the dissemination in

this country of a better knowledge of that country in which he himself was born. They could not have wished for any better initiation of the memorial which they had established in the hope of preserving some record of Birdwood and his life than the very brilliant essay which had just been delivered; and he thought if it were possible for their friend to have heard it, he also would have estimated at a very high value the contribution which Sir Valentine Chirol had made to the work which he had nearest his heart.

Sir Henry concluded by expressing the thanks of the Council to Lord Meston for presiding and assisting the Society in the establishment of the Birdwood Memorial.

The motion was carried unanimously, and Sir Valentine Chirol having briefly acknowledged the compliment, the meeting terminated.

SHEEP FARMING IN PATAGONIA AND TIERRA DEL FUEGO.

The profit in sheep farming on a large scale in Patagonia and Tierra del Fuego during the last three years is shown by the annual statements of La Sociedad Explotadora de Tierra del Fuego, of Valparaiso and Punta Arenas, one of the largest, if not the largest, sheep-farming companies in the world. The concern has a capital of £1,800,000, and controls, under deeds and Government leases, 945,770 hectares (2,337,038 acres) of land, the greater part of it on the island of Tierra del Fuego. To inclose its farms the company has built to date 8,297 kilometres (5,155 miles) of wire fence.

The statements cover the period from July 1, 1916, to June 30, 1919, and show a total profit in the three years of £2,721,947, or £921,948 in excess of the capital. Dividends totalling £1,980,000, or 110 per cent. were paid. The company marketed a total of 26,929,127 pounds of wool, and sold for meat 991,747 animals. The average price per pound received for wool in the fiscal year 1916-17 was 20·07*d.* (40·69 cents); in 1917-18, 29·22*d.* (59·24 cents), and in 1918-19, 23·58*d.* (47·80 cents). The price per head received for the sheep sold for meat was 17*s.* 7*d.* (4·27 dols.) in 1916-17; 17*s.* ½*d.* (4·14 dols.) in 1917-18, and 20*s.* 10½*d.* (5·07 dols.) in 1918-19.

The number of sheep sheared by the company in 1916-17 was 1,173,219; in 1917-18, 1,184,224; and in 1918-19, 1,139,505.

La Sociedad Explotadora de Tierra del Fuego is a Chilean company, but the general manager and all farm managers are British.

ARGENTINE CARPET WOOLS.

The so-called carpet wools of Argentina are known in that country as *criollo* (creole or native) wools. For some reason or other they have been known in the United States as Cordova (Cordoba) wools, and were formerly so denominated in the older United States tariffs. As a matter of fact, however, these creole or carpet wools are produced not only in the Province of Cordoba, but in those of Mendoza, Santiago del Estero, San Luis, and in a part of the Territory of La Pampa. There are various odd sorts produced in other provinces, but these amount to nothing of importance in connection with carpet wools.

Taking into consideration the length of staple and the shrinkage, the best native wools are those from Cordoba, Mendoza, and San Luis, although it is believed, in the absence of actual official statistics, that the Province of Santiago del Estero produces more of these wools than any other province; and, while it is generally short in staple on account of its frequent shearing, it nevertheless sells for about the same prices as other wools in a normal market. On the average, creole wool will yield from 47 to 55 per cent. when clean scoured.

At the end of 1915 the three leading provinces of Argentina in the numbers of sheep were:—Buenos Aires, with 18,535,935; Entre Rios, with 4,413,545; and Corrientes, with 2,410,279. According to the third national census of 1914, these three provinces had, respectively, only 425,660, 488,655, and 509,956 criollo or native sheep; while the same census showed a preponderance of these native sheep in other provinces, as follows:—

Provinces and classes of sheep.		Number of sheep.
Cordoba	Pure	32,242
	Mixed	713,408
	Native	664,836
Mendoza	Pure	973
	Mixed	46,099
	Native	251,415
Santiago del Estero	Pure	195
	Mixed	18,656
	Native	723,058
San Luis	Pure	27,885
	Mixed	231,847
	Native	332,378

The above figures give some idea of the proportion of native wool produced in the respective provinces.

The sheep are pastured principally in the valleys or at the foot of the hills in the above-named provinces, and the flocks are small compared with those in the more important sheep provinces. The crudest conditions exist, and probably the only reason that the sheep are, as a rule, driven into a corral of thorns at night is the fear of wild animals. The sheep must be exceedingly hardy, since the climate is hot and the pasturage scanty in summer, and the cold severe in winter. On account of the sudden climatic changes that take place, the mortality is greater from cold than from diseases, especially after shearing time. In the provinces of the north of the Republic, the only sheep are the

creole, as the pasturage would not suit other classes. With the exception of the highest priced pure-bred breeding sheep, all sheep in Argentina, even in the coldest regions of the extreme south, are pastured in the open, and are not given any feed in addition to the pasturage during any part of the year.

The methods of tending the flocks and shearing the sheep are primitive. The average clip per sheep is about 5½ lb., the fleeces of those raised toward the plains or at the foot of the hills being the lighter, while the fleeces of the districts of high altitude contain more grease and weigh probably from 7·7 to 8·8 lb. In all creole wool there is a trace of merino, so far as fineness is concerned; for, while the points and possibly half of the staple may be coarse, at the roots and even in some of the fleeces there is a fineness which could only have originally come from the merino or Rambouillet. In other words, there are no longer any strictly native or creole sheep any more in Argentina, the mixture having come about through primitiveness or carelessness in the tending of the herds.

It appears from a report by the United States Consul-General at Buenos Aires, that during the past fifteen or twenty years the production of carpet wool in Argentina has been decreasing, and the export has fallen off considerably because of the increasing use of the wools in the domestic market. The making of wool mattresses in Argentina has greatly increased. These mattresses are commonly used in South American countries, about 90 per cent. being made of creole wool, which is superior for this purpose to any other class of wool because it retains an elasticity which can be constantly renewed by opening out the mattresses.

The individual producer of creole wool runs an account with the nearest important store, and he exchanges his sheep or his wool for stores or sells for cash. The stores in turn sell to the travellers of the export houses in Buenos Aires, Rosario, and other cities, or they send the wool to the Argentine markets against an advance from the firms or brokers in those markets. There is not much fear of control by special interests, because hides, skins, hairs and other animal products are, as yet, bought more or less through the same dealers.

A notable feature in the creole wool business is the heavy taxation, since, apart from the national export tax, wool and other products are subjected to a provincial tax when they are exported from a province. The rates vary in each province. Wool coming from the provinces of Entre Rios, Corrientes, and Buenos Aires, and from the Territory of Santa Cruz, in which are included the best wools that the country produces, pay smaller export taxes than the creole and other inferior wools. Since, therefore, the raiser of these carpet wools receives less consideration, as compared with the growers of wool living in the more fortunate provinces, it is easy to arrive at the reason for the constant decrease and the semi-abandoned trade in these cheap wools.

MUSK TRADE OF CHINA.

In normal years the exportation of musk from China averages in value upwards of £75,000. The Great War and disturbed conditions in China have interfered with this trade. The musk is collected principally on the Tibetan-Chinese frontier, the city of Tachienlu being credited with handling the commodity to the value of 300,000 taels annually.

The following particulars, received in Shanghai from Tachienlu, have been made the subject of a report by the United States Consul-General at Shanghai:—

The chief point for the collection of musk on the Tibetan-Chinese border, the city of Tachienlu, draws its supply from a wide area, the musk being brought in by hunters and traders, and by Chinese merchants or their representatives in the interior. This article, which is obtained from the male musk deer (being the secretion of a certain gland), is received in its original form in what is known as a pod—a small, contracted skin pouch, seldom larger than a walnut. A pod sometimes contains as much as 2 oz. of musk, but usually the amount is less than an ounce. From Tachienlu, and other interior towns where it is collected, the musk is shipped in the pod form to the coast during the cooler months of the year, as, owing to the heat and moisture, it is likely to mould and spoil if shipped during the hot season.

The high value of musk offers a strong inducement for its extensive adulteration. In consequence of such adulteration, which is often most difficult to detect, it is considered a good average if, in a year's purchases, as much as 80 per cent. of pure musk is obtained. Among the adulterants used may be mentioned peas, barley, grains of wheat, mashed acorns, fried liver, and pulverised beef. It may be of interest to note the average prices for musk which have prevailed in Tachienlu in recent years:—1914, 15 taels per ounce, gross weight; 1915, 13 taels; 1916, 11 taels; 1917, 11 to 12 taels; 1918, 11 to 12 taels; and 1919, 12 to 24 taels. (The value of the haikwan tael has risen from 2*s*. 8½*d*. in 1914 to 5*s*. at the end of 1919.)

The number of deer killed annually to supply the musk market is enormous. In a general way it may be said that twenty-two pods of musk are required to make 1 catty (1·33 lb.). It will be seen, therefore, that the production of 1 catty of musk represents the destruction of at least twenty-two deer. Moreover, in taking the animals, the females and the young

are slaughtered indiscriminately, notwithstanding the fact that the musk pod is obtained only from the full-grown male deer. It may be said, in passing, that the venison is esteemed a great delicacy among the Chinese, while the hide, which is remarkable for its softness, is of considerable commercial value. It is estimated that more than 100,000 deer are slaughtered annually in supplying the musk market of the towns on the Szechuan-Tibetan border. From this it would seem that should there be an increase in the demand for musk the animals might be exterminated. In view of this contingency, there has been suggested the feasibility of rearing the deer in captivity with a view to drawing off small quantities of the musk annually.

OIL-YIELDING PRODUCTS AND SEED-CRUSHING INDUSTRY OF EGYPT.

Among the oleaginous products of Egypt and the Anglo-Egyptian Sudan, cotton seed is the only one of interest to the world's markets. The exportation of groundnuts and sesame is limited to adjacent territory, and is not important. Almost the entire production of oleaginous material is the result of cultivation, but statistics of production are not available. About 50 per cent. of the groundnuts, all of which emanate from the Sudan, are consumed as human food.

As a general practice, writes the United States Consul at Alexandria, the Egyptian cultivators divide their land into three parts: One part is planted in cotton; one in dura (native grain); and one in berseem (fodder). About 75 per cent. of the cultivated land is held by individuals owning less than 2 acres. On these small patches no machinery is used, and only the most antiquated implements are employed. In Lower Egypt water is raised from irrigation ditches, for the most part, by hand-manipulated spiral lifters. In Upper Egypt this water lifting is done generally by an apparatus consisting of a bucket attached to a pole with a balance weight.

The only crushing of commercial importance in Egypt is limited to cotton seed. The cotton seed crushing industry in Egypt was established, and is maintained solely for the purpose of supplying the local demand for cottonseed oil. Only a very small proportion of the oil produced is exported; in normal times none of the cake is consumed locally. The entire supply of seed crushed by Egyptian mills is of local origin.

Egyptian mills are equipped with modern machinery, having been reconstructed periodically. The quality of the oil is good. Most of the mills are operated on scientific principles and employ chemists. The total approximate production of oil and cake in Egypt during 1913 was 11,150 metric tons of oil, and 63,000 tons of cake. Owing to the allotment system inaugurated by the Cotton Seed Control Board, the production during 1918 very much decreased. Statistics of oil production, as such, are not available, but may be approximated from the quantity of oil cake exported (all the cake produced in normal times is exported), at the ratio of $5\frac{2}{3}$ to 1. During the war no cake was exported. A large quantity was consumed locally as fuel. A ton of 2,000 lb. of Egyptian cotton seed will yield approximately 330 lb. of oil and 1,600 lb. of cake.

NOTES ON BOOKS.

A Manual of the Timbers of the World, their Characteristics and Uses. By Alexander L. Howard. London: Macmillan & Co. 30*s*. net.

The object of this work, as stated in the preface, is "to meet a distinct want for a clearly-arranged handbook which shall contain information concerning all the timbers encountered in commerce, including those which have only of recent years appeared in the European market. The aim has been to treat the subject from its commercial, technical, and industrial aspects."

The main portion of the book consists of a catalogue of timbers, beginning with *Abey*, a wood much resembling mahogany, that comes from San Domingo, and ending with *Zizyphus Jujuba*, a wood not unlike the black walnut, which grows in India. Between these extremes are descriptive notes of some 450 timbers, illustrated in many instances with excellent photographs. The notes give careful descriptions of the woods, their colours and markings, and indicate the various uses to which they are specially adapted. To carry out this work as effectively as it is here done requires an immense amount of experience. Mr. Howard has been connected with the timber industry for over forty years, and in most instances he speaks from personal knowledge of the merits and characteristic qualities of the materials described; in other cases he quotes from high authorities whose names he gives.

It will be seen at once that a work of this kind will prove of the utmost value to all whose business it is to study the uses of different timbers. As the book is arranged alphabetically reference is rendered very easy. If one might make a trifling suggestion it would be that in future editions the names of the trees should be printed at the top of the pages on which they are described, as is usually done in the case of dictionaries.

In addition to the actual facts set forth in the catalogue, Mr. Howard discusses incidentally many points of great interest. He mentions, for instance, the tendency to demand Austrian oak in British specifications, and we are glad to find in him a stalwart champion of the English tree. A useful section is devoted to the artificial seasoning of timber, where he states the interesting fact that he had had experience of some very large timber

dryers in Finland used to fulfil certain conditions, one of which was "to turn out the dry timber without discoloration, so that it could be sold in England and elsewhere as 'Guaranteed NOT Kiln-dried.'"

We note with pleasure that particulars are given of the properties of several Indian timbers, such as Alexandrian Laurel (*Calophyllum Inophyllum*), which hitherto have been little known in this country. Any one who visited the Empire Timber Exhibition, recently held at Holland Park Skating Rink under the auspices of the Department of Overseas Trade, must have been greatly struck by the exhibits of these woods which were prepared by Mr. Howard for the Government of India. Attention was drawn to these in the *Journal* of July 16th (p. 567), and we can only repeat the hope there expressed that these timbers will become more and more widely known among our furniture makers.

GENERAL NOTES.

JAPANESE LABOUR.—A report on industrial conditions in Japan, by H.M. Vice-Consul at Osaka, describes (Cmd. 511) the social problems associated with the establishment and expansion of industries. Up to the present it is stated that the Government in Japan has made little effort to deal with the situation. A Factory Act was passed in 1916, but its most important provision—the prohibition of night work for women and young persons—is not to come into operation until 1933. Working hours were fixed at twelve, but exemptions are granted to factories where only males over fifteen years of age are employed, and to silk factories until 1931. The prohibition of the strike has hindered the organisation of labour and retarded the development of trade unionism. Conditions in the towns appear to be very bad, with the inevitable result that epidemics are very frequent. Rents are high owing to the scarcity of houses, and this is leading to the rapid growth of slums, in which some of the houses have no flooring but the bare earth, and no ventilation. Wages are low despite the increases which have been given during the war, labour being very plentiful and inefficient. It is usual for all members of a family who are old enough to work from early morning to late at night—many Japanese industries still being carried on in the home. The hours worked in the factory are usually eleven or twelve a day, with three or four days' holiday in the month, the machinery running night and day. The average wages of the males employed by forty three cotton spinning companies have risen from 1*s*. a day in 1914 to 1*s*. 8*d*. in 1919; the wages of women have risen from 7¾d. in 1914 to 1s. 2¼d. in 1919. Three-quarters of the labour employed by spinning and weaving companies consists of women and children. Girls from the age of sixteen to twenty-two come into the mills from the country districts and work ten or twelve hours a day and go on night work every alternate week. They are housed on the premises and fed by their employers for a nominal charge; their wages vary from 6*d*. to 1*s*. 8*d*. a day. At present the average working period for a girl is about one year. Many large firms are now taking a great interest in their employees and are providing medical attendance, playgrounds, and shops where cheap luxuries can be bought.

THE AUSTRALIAN BLACKBOY TREE.—A peculiar product of the vegetable world is what is known as the "blackboy" tree, which flourishes in the State of Western Australia. It is, in fact, a species of the grass tree, and grows to a normal height of 7 to 10 feet, and is found to be useful for a variety of purposes. Until recently no attempt has been made to utilise the tree commercially, but, according to a report published in the *Weekly Bulletin* of the Canadian Department of Trade and Commerce, a company has now been formed to work and market its by-products. The plant consists of nineteen sets of retorts and furnaces, condensers, receiving tanks, etc., and can deal with 100 tons of gum and other material derived from the tree. The company at present employs about twenty men, besides cutters, and among other things being produced are tars (free from harmful acids), tarpaulin dressings, rope tar and sanitary tar, lacquers (such as Japan black), steam and refrigerating pipe lagging, paint for ironwork that requires stoving at high temperature, stains and paints, pitches for marine insulating, phenol, benzol, and alcohols, coke, potash and pyrogeneous acid. The production of dyes, perfumes, and formalin, and various kinds of varnishes is also planned. The formation of this company is the outcome of experiments made by the late Mr. Henry Lowley, the city analyst of Perth, who devised the methods of extracting and treating the gum, pith, and fibre of the tree.

PHOSPHATE DEPOSITS IN THE NETHERLANDS.—According to a report by the United States Commercial Attaché at The Hague, phosphate deposits have been discovered in the eastern part of Holland, at a place called Ootmarsum, in the Twente District. About 30 tons of 15 to 20 per cent. phosphate are being produced each day, and are being sold locally at prices corresponding to the prices of imported phosphate. The stratum varies from 7 inches to 3 feet in thickness, but on account of the fact that it is not continuous the work of extracting the rock is very expensive. In some places the stratum is on the surface; in others it is as much as 25 feet beneath the surface.

TOBACCO PIPES FROM AUSTRALIAN WOODS.—Tobacco pipes are now being made from Australian woods, which in appearance and finish compare very favourably with imported pipes of good quality. In one of these factories in Melbourne all of the work is done by disabled Australian soldiers, and employment is reserved for them exclusively.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

SYNTHETIC DRUGS.

By JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S.,

Emeritus Professor of Chemistry, East London College.

Lecture I.—Delivered December 1st, 1919.

In attempting to give an adequate account of the synthetic drugs in a course of three lectures it is necessary that somewhat circumscribed limits should be set regarding the matters considered. The term synthetic drug implies that a substance is artificially produced and that it finds a use in medicine, so that numerous fairly simple compounds could be logically included. Common usage has, however, restricted the term to more or less complex carbon compounds which are either prepared by truly synthetic methods (*e.g.* veronal) or by modifying the structure of naturally occurring compounds by oxidation, reduction, acylation, alkylation, etc.

Accepting this generally implied meaning we should include on the one hand simply-constituted compounds like chloroform and ethylchloride, and on the other complicated compounds such as diacetylmorphine. The preparation of the simpler compounds can be assumed to be known to those present, in fact it would be impossible to afford time for treating them in anything but a cursory manner.

Time also prevents more than passing remarks being made about the various colloidal metallic preparations, in fact these can scarcely be described as "synthetic" in a strict sense.

CLASSIFICATION.

The subject-matter to be dealt with may be classified either on the lines of systematic organic chemistry, dealing with the members of one class of compounds at a time, or arranged according to the effect produced, considering disinfectants in one group, hypnotics in another, and so on; this is the course which has been most generally followed. In adopting a classification based on chemical considerations the saving of time thereby accruing has had considerable influence, and the survey of the subject may be rendered more systematic, whilst the lecturer being a chemist himself feels on safer ground.

Since chloroform was one of the first artificial compounds to be used in medicine or surgery we may well begin with the derivatives of the simpler hydrocarbons.

DERIVATIVES OF THE ALIPHATIC HYDROCARBONS.

Small amounts of the paraffins and olefines have no very pronounced action on the organism, but their halogen substitution derivatives have in many cases well-marked anæsthetic properties.

Methyl Chloride—CH_3Cl, b.p. $-24°$—is obtained either from methyl alcohol and hydrochloric acid in presence of zinc chloride (Groves, *Annalen*, 1874, 174. 378), or by heating trimethylamine hydrochloride obtained from beet molasses (Vincent, *Jahresb.* 1878. 1135). It is used as a spray to produce local anæsthesia, and in lumbago, neuralgia and sciatica; its action on the skin, however, is against it.

Methylene Chloride—CH_2Cl_2, b.p. 41·6°—is obtained from methylene diodide and chlorine, by the reduction of chloroform and by the action of phosphorous pentachloride on polyoxymethylene.

Chloroform—$CHCl_3$, b.p. 61°—was first introduced as an anæsthetic by Simpson in 1848. It is obtained by the action of bleaching powder on alcohol or acetone, or by the decomposition of chloral by alkalies. It is also formed by partial reduction of carbon tetrachloride.

Carbon Tetrachloride—CCl_4, b.p. 77°—can be obtained by the action of chlorine on carbon disulphide in the presence of antimony. Its action on the human organism is harmful.

Ethyl Chloride—C_2H_5Cl, b.p. 12·5°—is formed when hydrogen chloride acts on ethyl alcohol in

presence of a metallic (*e.g.* zinc) chloride. It is chiefly used for producing anæsthesia in minor operations, sometimes in conjunction with ether and chloroform.

Ethylene Dichloride—$C_2H_4Cl_2$, b.p. 84°—has found use as an anæsthetic; S. J. Wallace has employed it as a solvent for iodine in disinfecting the skin (*British Medical Journal*, 1910, 1288).

Dichloroethylene (Acetylene dichloride, dioform)—$C_2H_2Cl_2$, b.p. 55°—is said by Villinger to have given good results as an anæsthetic; the number of experiments was rather limited.

Bromoform—$CHBr_3$, m.p. 7·5°, b.p. 151°—is obtained by the action of alkaline hypobromites on alcohol or acetone, or by electrolysis of a solution of potassium or calcium bromide in dilute alcohol (Schering, D.R.P. 29771). It is used in whooping-cough.

Ethyl Bromide—C_2H_5Br, b.p. 38°—is prepared by distilling a mixture of alcohol and sulphuric acid with a bromide. Separation from accompanying ether is difficult owing to the nearness of the boiling points; Riedel suggests agitation with concentrated sulphuric acid (D.R.P. 52982). Ethyl bromide is an anæsthetic.

Iodoform—CHI_3, m.p. 119°—is obtained by the action of iodine and an alkali or alkaline carbonate on alcohol, acetone, etc. The production of iodoform by electrolysing an aqueous alcoholic solution of potassium iodide and sodium carbonate (Schering, D.R.P. 29771) must be looked on as a modification of the former process. Iodoform may also be obtained electrolytically from acetone (Teeple, *Journal of the American Chemical Society*, 1904, 26. 170).

Alcohols.

The aliphatic alcohols employed as such, or as esters in medicine, are usually non-synthetic in origin; a few artificially prepared alcohols, mostly containing halogen, have been introduced.

Trichloroisopropyl Alcohol (Isopral)—$CCl_3 \cdot CHOH \cdot CH_3$, m.p. 49°. This compound was introduced as a hypnotic (Bayer, D.R.P. 151545), being obtained by the action of methylmagnesium bromide on chloral.

Trichloro-tert.-butyl Alcohol (Chlorbutol, Acetone-chloroform, Chloretone)—$(CH_3)_2(CCl_3)COH$, m.p. near 97°, b.p. 170–171°—was obtained by Willgerodt (*Ber.* 1882, 15. 2308, Willgerodt and Gemeiser, *J. pr. Chem.*, 1888, 37. 365), by the action of caustic potash on a mixture of acetone and chloroform. The reaction is never complete; it was thought at first that there were two modifications, but Cameron and Holly (*Journal of Physical Chemistry*, 1898, 2. 522) have shown that the only "acetone-chloroform" is the crystalline substance smelling like camphor and melting, if anything, above 97°. The supposed liquid modification is simply the same substance mixed with acetone and water. They explain the formation of the compound thus:—

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CO + KOH = \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C\!<\!\begin{matrix}OH\\OK\end{matrix}$$

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C\!<\!\begin{matrix}OH\\OK\end{matrix} + CHCl_3 = \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C\!<\!\begin{matrix}OH\\CCl_3\end{matrix} + KOH$$

Besides possessing hypnotic properties, chlorbutol acts as a local anæsthetic, analgesic, and antiseptic.

Brometone—$(CH_3)_2(CBr_3)COH$, m.p. 167°—also possesses hypnotic and analgesic properties. It has been recommended in sea-sickness.

Tertiary Amyl Alcohol (Amylene Hydrate)—$(CH_3)_2(C_2H_5)COH$, b.p. 102·5°—was first obtained in a pure condition by the action of zinc methyl on propionyl chloride (Popoff, *Annalen*, 1868, 145. 292). It is more easily made by Wischnegradsky's method (*Annalen*, 1877, 190. 332). Ordinary commercial amylene such as is obtained by dehydrating fusel oil with zinc chloride (Wurtz, *Bull. Soc. Chem.* 1863, 5. 301) consists chiefly of trimethylethylene. This, when shaken with diluted sulphuric acid, unites with water to form the tertiary alcohol.

Amylene hydrate has been used as a hypnotic, intermediate in its action between chloral hydrate and paraldehyde.

Aldehydes.

Aldehydes are formed by the oxidation of primary alcohols. The two simplest aldehydes, either monomolecular or polymerised, find very extensive application.

Formaldehyde (CH_2O). This compound was obtained by Hofmann in 1867 (*Proceedings of the Royal Society*, 16. 156), both as a gas and as solution in dilute methyl alcohol. Air was saturated with the vapour of methyl alcohol and led over a spiral of platinum wire, a limited and flameless combustion taking place.

Trillat first developed the oxidation process technically (French patent 199919, 1889; D.R.P. 55176), using platinised asbestos or other contact substance. Further modifications were introduced by Klar and Schulze (D.R.P. 106495). Bone and his co-workers (*Transactions of the Chemical Society*, 1903, 83. 1074; 1904, 85. 1637; 1905, 87. 1232) found that formaldehyde

was an intermediate product of the combustion of methane and other hydrocarbons, and Glock (D.R.P. 109014) has suggested the oxidation of methane over granulated copper at 600° as a method of making formaldehyde.

Various other methods of oxidising methyl alcohol have been devised, *e.g.*, by manganese salts in acid solution (Lang, D.R.P. 166357), ammonium persulphate (Ditz, *J. pr. Chem.* 1909, ii. 78. 359), moist chlorine (Brochet, *Compt. rend.*, 1896, 122. 130, 1156), etc. The formation of formaldehyde and hydrogen by leading methyl alcohol vapour over finely divided copper at 200° is of special interest in view of the use that has been made of the corresponding reaction in the case of ethyl alcohol (Sabatier and Senderens, *Compt. rend.* 1903, 136. 922).

Whilst the technical processes of producing formaldehyde depend on the oxidation of methyl alcohol, it is well to remember that the compound has been obtained by reduction of formic acid and even carbon dioxide (Badische, D.R.P. 185932; Fenton, *Transactions of the Chemical Society*, 1907, 91. 687; Bach. *Compt. rend.* 1898, 126. 479; K. Jahn, *Ber.* 1889, 22. 989; Chapman and Holt, *Transactions of the Chemical Society*, 1910, 97. 917; Brodie, *Annalen*, 1874, 174. 284; De Hemptinne, *Bull. Acad. roy. Belgique*, 1897, ii. 34. 269; Losanitsch and Jovitschich, *Ber.* 1897, 30. 136; Löb. *Z. El. Chem.* 1905, 11. 749; 1906, 12. 295).

The formalin or formol of commerce usually contains 40 per cent. of formaldehyde, together with 8 to 20 per cent. of methyl alcohol dissolved in water.

Formaldehyde is easily polymerised by acids.

Paraformaldehyde is at least a three-fold polymer.

Trioxymethylene is obtained by the action of sulphuric acid on formaldehyde solution (Cambier and Brochet, *Compt. rend.* 1894, 119. 607). According to Auerbach and Barschall (*Arb. Kais. Gesundh. Amt*, 1907, 22. 584) four polyoxymethylenes (α, β, γ, δ) can be prepared; the commercial trioxymethylene consists of the γ or $\beta + \gamma$ modifications. A really crystalline α-trioxymethylene may be prepared from the commercial product by heating in a current of nitrogen and fractionating the condensate (m.p. 63–64°, b.p. 114·5°). This substance does not show aldehydic reactions, and is evidently a cyclic compound.

Paraformaldehyde differs chiefly from this compound by amorphous condition and content of absorbed water.

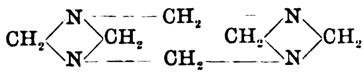
The disinfectant properties of formaldehyde make it valuable in itself. Additionally it is used in the preparation of derivatives which undergo hydrolysis with liberation of formaldehyde.

Hexamethylene-tetramine (Formamine—$C_6H_{12}N_4$) is also used under a variety of names, *e.g.*, Hexamethylenamina (U.S.P.), Hexamine, Aminoform, Urotropine, Cystamin, Formin, Metramin, Urisol, Uritone, Vesalvine, Xametrin.

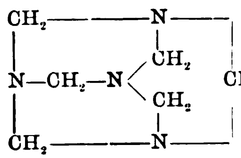
The compound was first obtained by Butlerow (*Annalen*, 1860, 115. 322) by the action of ammonia on polyoxymethylenes. It may also be obtained by the action of ammonia on other methylene compounds. According to Wohl, formaldehyde vapour is led into concentrated aqueous ammonia, the solution evaporated, being kept ammoniacal meanwhile, and the resulting syrup dissolved in hot absolute alcohol (*Ber.* 1886, 19. 1842). Grassi and Motta (*Gazzetta*, 1899, 29. 1, 43) dissolve polyoxymethylene in concentrated aqueous ammonia and then evaporate with occasional addition of ammonia.

One hundred parts of the following solvents at 12° dissolve hexamethylene-tetramine in the respective amounts—water, 81·3; alcohol, 3·22; chloroform, 8 parts. The compound is not appreciably soluble in ether (Delépine, *Bull. Soc. Chim.* 1895, iii. 13. 353).

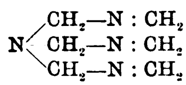
Various constitutional formulæ have been proposed, *e.g.*—



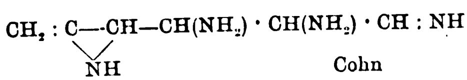
Van 't Hoff



Duden and Scharff



Löschkaun



Cohn

Hexamethylene-tetramine has an alkaline reaction, and is a monocid base, forming such salts as $C_6H_{12}N_4 \cdot HCl$. Moreover, it unites with one molecule of an alkyl halide (Vohle, *Ber.* 1886, 19. 1840; Delépine, *Bull. Soc. Chim.* 1895, iii. 13. 355). Some acid salts have been prepared, *e.g.* $C_6H_{12}N_4(HNO_3)_2$ and three metaborates with 1, 2 and 3 molecules of HBO_2 have been patented (A.-G. Anilinfabrik, D.R.P. 188815).

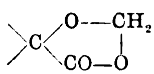
It is enerally supposed that the antiseptic value of hexamethylene-tetramine depends on the liberation of formaldehyde by acid hydrolysis; on the other hand, E. Zak considers it to be itself an efficacious antiseptic.

Numerous salts and addition products have been introduced under trade names; the following list makes no pretence at completeness:—

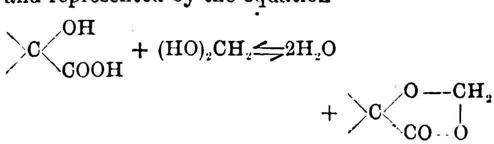
Amphotropin.	Camphorate.
Bromalin.	$C_6H_{12}N_4 \cdot C_2H_5Br$.
Cystopurin.	$C_6H_{12}N_4(NaC_2H_3O_2)_2+6H_2O$.
Formicin.	Acetamide addition product.
Hetraline.	Resorcin compound.
Hexal.	Sulphosalicylate.
Hexamecol.	Guaiacol compound.

The above compounds are intended mostly as antiseptics or disinfectants, but bromalin has been used as a substitute for the alkaline bromides in the treatment of epilepsy.

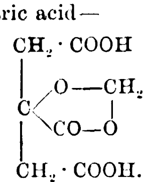
Formaldehyde is readily liberated from a certain type of ether-ester. These substances, discovered by W. A. Alberda van Ekenstein (*Proc. K. Acad. Amst.* 1900, 3. 400), contain the grouping—



and are produced by the action of formaldehyde on a-hydroxy-acids. The reaction is reversible and represented by the equation—



In this way citric acid gives the dibasic anhydromethylene-citric acid—



the sodium salt of which has been used under the name of "Citarine."

Formamol is the hexamethylene-tetramine salt of this acid. It is also known as Helmitol, Neurotropine, and Uropurgol. A mixture with hetraline is known as Citramine or Citraminoxyphen.

In the original process of making anhydromethylene-citric acid, formaldehyde solution was used and poor yields were obtained. These were subsequently improved by heating together a-hydroxy acid, trioxymethylene and chloroform for some hours at 150° (Lobry de Bruyn and van Ekenstein, *Rec. trav. Chim.* 1901, 20. 331). The preparation of anhydromethylene-citric acid, m.p. 205°, has also been described by W. Sternberg (*Pharm. Zeit.* 1901, 46. 1004).

Mesotan is methyoxymethyl salicylate ($C_6H_4(OH)COOCH_2OCH_3$), a yellow liquid with b.p. 162°/42 mm. It yields formaldehyde on hydrolysis (Eichengrün, *Pharm. Zeit.* 1902, 47. 857).

Methylene-ditannin (Tannoform)—$CH_2(C_{14}H_9O_9)_2$—is obtained by the action of hydrochloric acid on an aqueous solution of tannin and formaldehyde; it passes unchanged through the stomach, but tannin is liberated in the duodenum.

Glutol is a condensation product of gelatine and formaldehyde used as sheets or powder as an antiseptic dressing.

Acetaldehyde ($CH_3 \cdot CHO$, b.p. 21°). The older method of preparing aldehyde consisted in the oxidation of alcohol with chromic acid mixture. Sabatier and Senderens (*Compt. rend.* 1903. 136. 738, 922) found that alcohol could be actually "dehydrogenated" by passing its vapour over copper heated to 200° to 330°—

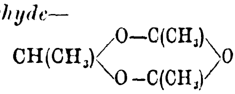
$$CH_3 \cdot CH_2OH = H_2 + CH_3CHO.$$

This reaction has proved capable of application on the large scale during the recent war.

The synthetic production of aldehyde by dissolving acetylene in sulphuric acid of sp. gr. 1·35, diluting with water and distilling (Lagermark and Eltekow, *Ber.* 1877, 10. 637) has been much improved by using a mercury salt as catalyst (Kutscherow, *Ber.* 1881, 14. 1540; 1884, 17. 13; Hofmann, *Ber.* 1898, 31. 2784. 1899, 32. 874).

Such application of catalysts made possible the production of aldehyde in very large amounts at the works at Shawinigan Falls (Canada).

Paraldehyde—



b.p. 125°, is used as a hypnotic. It is obtained by the polymerisation of aldehyde by hydrochloric acid, zinc chloride, etc.

Chloral—$CCl_3 \cdot CHO$, b.p. 97·7°—is official as the hydrate $CCl_3 \cdot CH(OH)_2$. Ethyl alcohol is chlorinated, the resulting chloral alcoholate decomposed by concentrated sulphuric acid and the free chloral combined with water.

Besson (D.R.P. 133021) recommends treating the product of the action of chlorine on alcohol in a gaseous state with moist chlorine.

Viferral is a polymerised chloral (C_2HOCl_3)x. obtained from chloral in presence of pyridine

(Gärtner, D.R.P. 165984). This hypnotic is a white powder which sinters at 150°, melts at 153-155°, and dissolves in hot water and alcohol, giving chloral hydrate and alcoholate respectively.

Chloralformamide (Chloramide)—$CCl_3 \cdot CH(OH)(NH \cdot CHO)$, m.p. 114–115°—is a slower hypnotic than chloral but is said to be safer. It is formed by the direct union of chloral and formamide.

Butyl Chloral Hydrate—$CH_3 \cdot CHCl \cdot CCl_2 \cdot CH(OH)_2$, m.p. 74–78°—is a weaker hypnotic than chloral obtained by the action of chlorine on paraldehyde or well cooled aldehyde. After dilution and neutralisation with calcium carbonate, the hydrate is distilled off and crystallised from water.

Ketone Derivatives.

Acetone—$CH_3 \cdot CO \cdot CH_3$, b.p. 56·5°—is chiefly of interest as an "intermediate" in the preparation of several drugs. It was formerly obtained from calcium acetate by distillation, but of late years use has been made of the observation that acetic acid distilled over a suitable catalyst yields acetone, water and carbon dioxide—

$$2CH_3COOH = CH_3 \cdot CO \cdot CH_3 + CO_2 + H_2O.$$

Methyl Ethyl Ketone—$CH_3 \cdot CO \cdot C_2H_5$, b.p. given variously between 78° and 81°—is obtained in the rectification of the products of wood distillation.

ββ - Bis - ethylsulphoneacetone (Sulphonal) —$(CH_3)_2C(SO_2C_2H_5)_2$—is a hypnotic, official in this country and in the United States.

When dry hydrogen chloride is passed into a mixture of 1 part of acetone and 2 parts of ethyl mercaptan, diethylthiodimethylmethane is produced (Baumann, *Ber.* 1885, 18, 887)—

$$(CH_3)_2CO + 2C_2H_5SH = H_2O + (CH_3)_2C(SC_2H_5)_2.$$

Baumann (*Ber.* 1886, 19. 2808) converted the compound into sulphonal by treatment with a 5 per cent. solution of potassium permanganate, dilute sulphuric acid being added from time to time. The mixture was heated and filtered, the filtrate then being concentrated. The sulphonal can be purified by recrystallisation from water or alcohol. Colourless prisms, m.p. 125° (127°–128° corr. Kempf).

Methylsulphonal (Trional) — $(CH_3)(C_2H_5)C(SO_2C_2H_5)_2$, m.p. 76°—acts more rapidly as a hypnotic; it is prepared from methyl-ethyl-ketone.

Ethylsulphonal (Tetronal)—$(C_2H_5)_2C(SO_2C_2H_5)_2$, m.p. 86°—is more soluble in alcohol than sulphonal.

For the use of ethylthiosulphuric acid in place of ethylmercaptan, see Bayer & Co. D.R.P. 46333.

Aliphatic Acids.

The aliphatic acids themselves will not receive any attention in this place, although formates are obtained synthetically from carbon monoxide, and acetic acid has recently been manufactured from calcium carbide by way of acetylene and acetaldehyde. The higher acids, both saturated and unsaturated, are usually derived from fats or by fermentation processes, so that our interest begins with the conversion of these acids into other substances.

Isovaleric Acid—$(CH_3)_2CH \cdot CH_2 \cdot COOH$—occurs as the bornyl ester in oil of valerian; the use of valerian and bromides in nervous troubles suggests the introduction of bromine into the valeryl group.

Bromoisovalerylcarbamide (Bromural)—$(CH_3)_2CH \cdot CHBr \cdot CO \cdot NH \cdot CO \cdot NH_2$—is stated to be a safe hypnotic.

Iodival—$(CH_3)_2CH \cdot CHI \cdot CO \cdot NH \cdot CO \cdot NH_2$—is the corresponding iodine compound, and may be used in many cases where iodides are generally employed.

a-Bromodiethylacetic acid gives rise to two hypnotics, the amide, *Neuronal*—$(C_2H_5)_2CBr \cdot CO \cdot NH_2$—and the ureide, Adalin—$(C_2H_5)_2CBr \cdot CO \cdot NH \cdot CO \cdot NH_2$.

Use has been made of bromine and iodine derivatives of the higher fatty acids to act as halogen carriers to the organism.

Calcium dibromobehenate (Sabromin) —$(C_{22}H_{41}O_2Br_2)_2Ca$—is a white powder without taste or smell. It is stated to be without action on the mucous membrane of the stomach and not to be absorbed before it reaches the intestine; consequently its use is recommended in cases of hysteria and other nervous affections.

Calcium monoiodobehenate (Saiodin)—$(C_{22}H_{42}IO_2)_2Ca$—is said to cause very slight or no iodism.

These halogenated behenic acids are obtained from erucic acid ($C_{22}H_{42}O_2$), which occurs as a glyceride in oil of hempseed, by the addition of halogen or halogen acid. In the case of monobromobehenic acid, the bromine may be replaced by iodine by warming with sodium iodide in glacial acetic acid solution, but a similar reaction cannot be carried out with the corresponding chloro-compound (Bayer and Co. D.R.PP. 180087, 186214, 186740, 187449, 187822, 215007, 215008, 215009).

For the amides and carbamides of higher

bromo- and iodo-aliphatic acids, see D.R.P. 248993.

Amino-acids.—It may be mentioned here that aminoacetic acid (glycocoll) possesses diuretic properties.

Cyclic Ureides.

The cyclic derivatives of carbamide frequently show very marked hypnotic action, veronal (diethylmalonylcarbamide) may be taken as typical of this class of compounds. The parent substance, barbituric acid, or malonyl-urea—

$$\begin{array}{c}\text{(6)}\quad\text{(1)}\\ \text{(5) } CH_2\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO \text{ (2)}\\ \text{(4)}\quad\text{(3)}\end{array}$$

was originally obtained from hydurilic acid and alloxantin, products of the action of nitric acid on uric acid.

The constitution was recognised from the fact that alkaline hydrolysis furnished malonic acid and urea, or, rather, the products of its fission. Confirmation of the structure was afforded by its synthesis which was effected by heating equal weights of malonic acid, urea and phosphoryl chloride to 100° (Grimaux, *Bull. Soc. Chim.* 1879, N.S. 31. 140).

$$CH_2(COOH)_2+(H_2N)_2CO = 2H_2O+CH_2\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO$$

Barbituric acid contains one atom of hydrogen replaceable by alkali metals, two atoms may be replaced by silver or lead. By acting on silver barbiturate with methyl iodide a dimethyl-barbituric acid was obtained which yielded dimethyl-malonic acid on hydrolysis (Conrad and Gutzeit, *Ber.* 1881, 14. 1643; Thorne, *Trans. Chem. Soc.* 1881, 39. 545). The compound was, moreover, quite different to the substance obtained by Mulder, who condensed malonic acid with *symm*-dimethylurea.

The constitution of the two isomerides is given by the formulae—

$$C(CH_3)_2\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO \qquad CH_2\left\langle\begin{array}{l}CO-N(CH_3)\\CO-N(CH_3)\end{array}\right\rangle CO$$

Conrad and Gutzeit also obtained a diethyl derivative from silver barbiturate and ethyl iodide (*Ber.* 1882, 15. 2849), which melts at 191° (182° C. and G.). Some years afterwards the hypnotic properties of this compound were recognised, and it was introduced under the name of veronal.

Barbitone (Veronal, Malourea, Malonal, Hypnogen) and its sodium derivative (Veronal-sodium, Medinal) enjoyed considerable popularity; its reputation has been somewhat damaged by the drug habit.

Proponal or Homalourea—

$$C(C_3H_7)_2\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO \qquad \text{and}$$

Luminal—

$$C(CH_3)(C_6H_5)\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO$$

were introduced at later dates, both being hypnotics.

Dibutylbarbituric acid is stated to combine pronounced sedative properties with but slight toxicity (Kamm and Vollweiler, U.S.P. 1331712).

Without entering into the merits or abuses of these hypnotics, it is worth considering at some length the synthetic methods by which they are produced, as illustrating the extensive research which is initiated by the introduction of a successful drug. Moreover, the methods and materials used in synthesising the 5,5-dialkylbarbituric acids warrant careful attention from their intrinsic chemical interest and their probable future use in synthesising other classes of compounds.

In place of carbamide, various related substances have been condensed with malonic or cyanoacetic derivatives, the carbonyl group of the urea portion of the nucleus being afterwards obtained as such. Thus Merck (D.R.P. 158591) condensed ethyl cyanoacetate with dicyandiamide—

$$CH_2\left\langle\begin{array}{l}CN\\COOC_2H_5\end{array}\right. + \left.\begin{array}{r}H_2N\\H_2N\end{array}\right\rangle C:N\cdot CN$$
$$= C_2H_5OH + CH_2\left\langle\begin{array}{l}C(:NH)-NH\\CO-\!\!-\!\!-\!\!-NH\end{array}\right\rangle C:N\cdot CN$$

and then hydrolised the resulting product to barbituric acid—

$$CH_2\left\langle\begin{array}{l}C(:NH)-NH\\CO-\!\!-\!\!-\!\!-NH\end{array}\right\rangle C:N\cdot CN + 4H_2O$$
$$= CH_2\left\langle\begin{array}{l}CO\cdot NH\\CO\cdot NH\end{array}\right\rangle CO + CO_2 + 3NH_3.$$

In subsequent processes it will be noted that the alkyl groups are generally introduced into the malonic or cyanacetic compound before condensation with carbamide or a substitute.

Bayer and Co. patented the following series of reactions—

$$CR_2\left\langle\begin{array}{l}CN\\COOC_2H_5\end{array}\right. + \left.\begin{array}{r}H_2N\\H_2N\end{array}\right\rangle C:NH$$
$$= C_2H_5OH + CR_2\left\langle\begin{array}{l}C(:NH)-NH\\CO-\!\!-\!\!-\!\!-NH\end{array}\right\rangle C:NH$$

D.R.P. 158592;

$$CR_2(CN)_2 + (H_2N)_2CS = CR_2\left\langle\begin{array}{l}C(:NH)-NH\\C(:NH)-NH\end{array}\right\rangle CS$$

D.R.P. 158621;

$$CR_2\left\langle\begin{array}{l}CN\\COOC_2H_5\end{array}\right. + (H_2N)_2CS$$

$$= CR_2\left\langle\begin{array}{l}C(:NH)-NH\\CO\text{------}NH\end{array}\right\rangle CS + C_2H_5OH$$

D.R.P. 162219;

and further (D.R.P. 165223) condensed ethyl malonate or cyanoacetate as well as malonitrile with dicyandiamide (X = NH or O)—

$$CR_2(COOC_2H_5)_2 \text{ or } CR_2\left\langle\begin{array}{l}CN\\COOC_2H_5\end{array}\right.$$

$$\text{or } CR_2(CN)_2 + (H_2N)_2C:N\cdot CN$$

$$\rightarrow CR_2\left\langle\begin{array}{l}CX\cdot NH\\CX\cdot NH\end{array}\right\rangle C:N\cdot CN.$$

For replacement of imino- or cyanimino-groups by oxygen, hydrolysis was resorted to, *e.g.* by boiling with 20 per cent. sulphuric acid, sulphur was removed by oxidation with nitric or nitrous acid or hydrogen peroxide. Einhorn (D.R.P. 165649) found that sulphur might also be replaced by oxygen by hydrolysis, whilst Meister, Lucius and Brüning (D.R.P. 170907), boiled with solutions of salts of heavy metals, *e.g.* lead acetate or copper chloride.

The imino-groups may also be removed by means of alkyl nitrites (Wolfes, D.R.P. 175592).

Merck also took patents for processes in which the alkyl groups were present in malonyl chloride before condensing it with derivatives of urea such as biuret or allophanic esters (D.R.P. 162220)—

$$CR_2(COCl)_2 + \begin{array}{l}H_2N\\HN\end{array}\!\!\left\rangle CO \right. \quad \searrow CO\cdot NH_2$$

$$= 2HCl + CR_2\left\langle\begin{array}{l}CO-NH\\CO\text{---}N\end{array}\right\rangle CO \quad N\searrow CO\cdot NH_2.$$

Other patents of Merck deal with the reactions—

$$CR_2\left\langle\begin{array}{l}CN\\COOC_2H_5\end{array}\right. + (H_2N)_2CO$$

$$= C_2H_5OH + CR_2\left\langle\begin{array}{l}C(:NH)\cdot NH\\CO\text{------}NH\end{array}\right\rangle CO$$

D.R.PP. 165561, 165562.

$$CR_2\left\langle\begin{array}{l}CN\\CN\end{array}\right. + (H_2N)_2C:NH$$

$$= CR_2\left\langle\begin{array}{l}C(:NH)-NH\\C(:NH)-NH\end{array}\right\rangle C:NH$$

D.R.PP. 165692, 165693.

$$CR_2\left\langle\begin{array}{l}CO\cdot NH\cdot CO\cdot NH_2\\CO\cdot NH\cdot CO\cdot NH_2\end{array}\right.$$

$$= CR_2\left\langle\begin{array}{l}CO-NH\\CO-NH\end{array}\right\rangle CO + CO\cdot(NH_2)_2$$

D.R.P. 174178.

A similar to the last is due to Traube—

$$CR_2(CO\cdot NH\cdot COOC_2H_5)_2$$

$$= CR_2\left\langle\begin{array}{l}CO\cdot NH\\CO\cdot NH\end{array}\right\rangle CO + CO(OC_2H_5)_2$$

D.R.PP. 172885, 172886.

Dicyandiamidine has also been used for condensations of this type (Von Heyden, D.R.P. 171147, Bayer and Co. 187990)—

$$CR_2(COOC_2H_5)_2 + \begin{array}{l}H_2N\\HN\end{array}\!\!\left\rangle CO \right. \quad \searrow C(:NH)(NH_2)$$

$$= 2C_2H_5OH + CR_2\left\langle\begin{array}{l}CO-NH\\CO\text{---}N\end{array}\right\rangle CO \quad N\searrow C(:NH)(NH_2)$$

Whilst Grimaux used phosphoryl chloride in his original synthesis of barbituric acid, reactions involving changes of types—

$$\cdot COOC_2H_5 + H_2N\cdot = C_2H_5OH + \cdot CO\cdot NH\cdot$$

$$CN + H_2N = \cdot C(:NH)\cdot NH\cdot$$

require the use of alkaline condensing agents. Alkali metals, their ethoxides, amides and cyanamides, and even calcium carbide, have been employed (Meister, Lucius and Brüning, D.R.P. 178934).

Dialkylmalonamides have also been directly condensed with phosgene (A.G. Anilinfabr. D.R.P. 167332) and with ethyl carbonate (Bayer and Co., D.R.PP. 168406, 168407).

The reaction—

$$CR_2\left\langle\begin{array}{l}COOR'\\CO-NH\end{array}\right\rangle \overset{NH_2}{\overset{|}{CO}} = R'OH + CR_2\left\langle\begin{array}{l}CO\cdot NH\\CO\cdot NH\end{array}\right\rangle CO$$

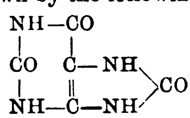
involves a complicated intermediate product (Boehringer, D.R.P. 193447).

Further alkylations of pyrimidine derivatives can only be mentioned (Schering, D.R.P. 174940; Einhorn, D.R.P. 193446).

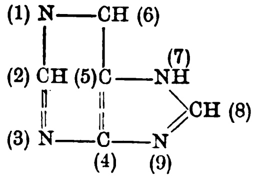
Chineosal is a trade name given to the quinine salt of diethylbarbituric acid.

PURINE COMPOUNDS.

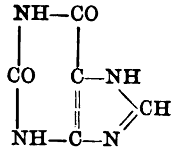
Xanthine, Caffeine, Uric Acid, etc., are all derivatives of urea; their relationships to one another and to Purine, their immediate ancestor, are shown by the following formulæ—



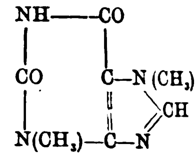
Uric acid.



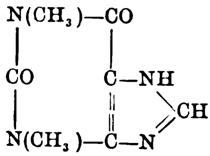
Purine.



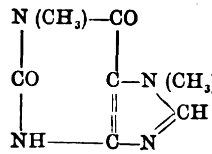
Xanthine.



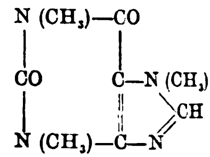
Theobromine.



Theophylline.



Paraxanthin.



Caffeine.

Derivatives of Purine have been used on account of their diuretic action, which is very slight in the case of xanthine, marked in the case of caffeine, and strongest with the dimethylxanthines. Of these, theophylline (Theocin) and paraxanthin are more effective than theobromine.

The solubility of theophylline and theobromine can be increased by the formation of double salts, which may be chosen to reinforce the desired properties. A few of these combinations may be mentioned—

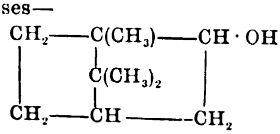
Euphyllin.	Theophyllin and Ethylenediamine.
Anisotheobromine.	Theobromine sodium and sodium anisate.
Agurin.	Theobromine sodium and sodium acetate.
Barutin.	Theobromine barium and sodium iodide.
Diuretin.	Theobromine sodium and sodium salicylate.
Eustenin.	Theobromine sodium and sodium iodide.
Theolactin.	Theobromine sodium and sodium lactate.
Theophorin.	Theobromine sodium and sodium formate.
Uropherin.	Theobromine sodium and lithium salicylate.

Paraxin is a synthetic product, being 1 : 7-dimethyl-8-dimethylaminoxanthin.

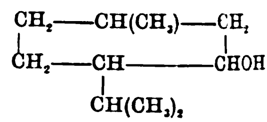
Derivatives of Cyclic Alcohols.

Three naturally occurring cyclic alcohols, borneol, menthol, and santalol, have found considerable uses—

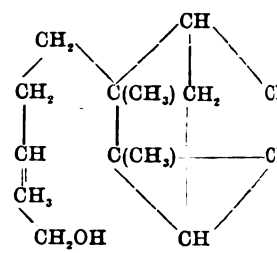
Borneol



Menthol



a-Santalol



The conversion of these alcohols into esters serves a twofold purpose, secondary reactions are avoided and the strong odour and taste are suppressed, or at any rate modified.

Bornyl isovalerate—$(CH_3)_2CH{\cdot}CH_2{\cdot}COOC_{10}H_{17}$—occurs in several oils (*e.g.* oil of valerian); the artificial ester, *Bornyval*, is used as a sedative and analeptic.

Bornyl isovaleryl glycolate—$C_4H_9{\cdot}COO{\cdot}CH_2{\cdot}COOC_{10}H_{17}$—is a colourless liquid, b.p. 42°/12 mm. It is almost without taste or odour, and is known as *New Bornyval.*

Bornyl a-bromoisovalerate (Valisan, Eubornyl)—$(CH3)_2CH{\cdot}CHBr{\cdot}CO_2{\cdot}C_{10}H_{17}$—is intended for use in nervous affections, *e.g.* neurasthenia and hysteria.

Bornyl aβ - dibromo - β - phenylpropionate (Adamon) — $(C_6H_5{\cdot}CHBr{\cdot}CHBr{\cdot}COOC_{10}H_{17})$ — has a sedative action, but is not hypnotic.

Tribornyl borate—$B(OC_{10}H_{17})_3$—is described by Zimmer and Co. (D.R.P. 188703), and Bayer and Co. obviate the intense odour of the three alcohols by conversion into alkyloxyacetic esters (D.R.P. 191547).

Menthyl isovalerate — $C_4H_9.COOC_{10}H_{19}$—is known as Validol.

Menthyl ethoxyacetate (Coryfin)—$C_2H_5{\cdot}O{\cdot}CH_2.COOC_{10}H_{19}$—and

Menthyl borate (Estoral)—$B(OC_{10}H_{19})_3$—are both used for nasal application.

Menthyl salicylate—$C_6H_4(OH)COOC_{10}H_{19}$—is known as Salimenthol.

Santalol (Arhéol, etc.). Sandalwood oil has enjoyed a considerable reputation as a disinfectant of the urinary passages, santalol being the active constituent. Hence esterification is useful in removing the inactive portion; the odour and taste are diminished and gastric irritation obviated or mitigated. The santalols may be obtained from East Indian sandalwood oil by heating with alcoholic potash, precipitating with water and rectifying under diminished pressure. For separating α- and β-santalols, Von Soden recommends conversion into the santalyl-phthalic acids and subsequent regeneration of the alcohols (*Arch. Pharm.* 1900, 238. 353).

Santalyl allophanate (Allosan)—
$NH_2{\cdot}CO{\cdot}NH{\cdot}COOC_{15}H_{23}$.

Santalyl carbonate (Blenal)—$CO(OC_{15}H_{23})_2$.

Santalyl camphorate (Camphoral)—
$C_8H_{14}(COOC_{15}H_{23})_2$.

Santalyl methyl ether (Thyreol)—
$C_{15}H_{23}, O{\cdot}CH_3$.

Santalyl salicylate (Santyl)—
$C_6H_4(OH)COOC_{15}H_{23}$.

The esters of these higher cyclic alcohols are prepared by a variety of methods: benzoates (Knoll and Co., D.R.P. 173240), isovalerates, stearates, etc. (Von Heyden, D.R.P. 182627), being obtained by the action of the acid chlorides in presence of pyridine. The carbonates and ethylcarbonates can be prepared in a similar manner, using phosgene or ethyl chlorocarbonate.

Salicylates are formed by heating with salol, phenol being eliminated; a small amount of sodium hydroxide is also added.

Mixed succinates and camphorates containing the methyl group have been introduced by Riedel (D.R.P. 208637), whilst Bayer and Co. have prepared carbonates containing menthyl or santalyl on the one hand and a salol or salacetol residue on the other.

Lecture II.—Delivered December 8th, 1919.

THE AROMATIC SERIES.

PHENOLS.

Phenol and its related compounds are largely used as antiseptics and disinfectants, whilst salicylic acid and its derivatives are used extensively in the treatment of rheumatic affections.

Phenol—C_6H_5OH—and its homologues are contained in coal tar, and are obtained from the first and second fractions of its distillation by extraction with alkali, separation by acid and rectification. In the last few years synthetic phenol has been very prominent as a source of picric acid for explosives. It is obtained by sulphonating benzene, isolating the product as sodium benzenesulphonate and fusing this salt with caustic soda.

Some ethers and esters of phenol may be mentioned.

Antodyne is the phenylether of glycerine—$CH_2(OC_6H_5){\cdot}CHOH{\cdot}CH_2OH$, m.p. 69°–70°—it has been introduced as a sedative.

Phenostal is diphenyl oxalate—$(COOC_6H_5)_2$—phenol is produced from it on hydrolysis.

Phenyform, a greyish white powder, for use in place of iodoform, is obtained from phenol and formaldehyde; it is said to be $C_6H_4(OH)(CH_2OH)$, $x\,CH_2O$.

Some of the simpler derivatives of phenol have found applications, *e.g.* *p*-chloro-phenol in dental surgery, and picric acid for burns.

Grotan is a name given to the sodium salt of chloro-*m*-cresol.

Attention may be drawn to a paper by Bechold and Ehrlich (*Zeit. physiol Chem.* 47. 173), who studied the action of halogenated phenols on diphtheria bacilli and various pathogenic bacteria. Generally, the introduction of halogen increases the activity; tetrabromo-*o*-cresol has a perceptible action on the organisms at a dilution of 1 in 200,000, whilst 1 in 800 is necessary with phenol. This particular compound is very slightly poisonous, but many halogenated phenols are as, or even more, poisonous than phenol itself.

Several derivatives of dihydroxybenzenes must be noticed.

Guaiacol—*o*-$C_6H_4(OH)(OCH_3)$—the monomethyl ether of catechol, occurs in beechwood tar, from which it can be extracted by a tedious process. Synthetic ways of preparing this compound are also known.

The valuable properties of beechwood creosote depend on the presence of guaiacol and its homologues; guaiacol, which is an antiseptic and deodorant, is used instead of creosote for internal administration in phthisis.

A number of esters derived from guaiacol have been introduced.

Phosphate—$PO(OC_6H_4OCH_3)_3$, m.p. 98°—from phosphoryl chloride and guaiacol sodium.

Carbonate (Duotal)—$CO(OC_6H_4OCH_3)_2$—is a tasteless, odourless, white, crystalline powder, m.p. 88°, obtained by the action of phosgene on a caustic soda solution of guaiacol.

The so-called creosote carbonate similarly obtained from creosote may be mentioned here.

Iso-Valerate (Geosote)—$C_4H_9 \cdot COOC_6H_4OCH_3$—is a liquid boiling between 245° and 265°.

Camphorate (Guacamphol)—$C_8H_{14}(COOC_6H_4OCH_3)_2$.

Benzoate (Benzosol)—$C_6H_5 \cdot COOC_6H_4OCH_3$, m.p. 50°–52°.

Cinnamate (Styracol)—$C_6H_5 \cdot CH : CH \cdot COO C_6H_4OCH_3$, m.p. 130°.

Monoiodo - guaiacol — 1 : 2 : 4-$C_6H_3(OH)(OCH_3)I$—has been used in chronic polyarthritis and pulmonary tuberculosis.

Resorcin—m-$C_6H_4(OH)_2$—possesses disinfectant properties; ointments are used containing this substance and zinc oxide. Resorcin is obtained by fusing sodium benzenedisulphonate with caustic soda. The monoacetyl derivative is known as *Euresol*.

Pyrogallol, being obtained from gallic acid, is hardly a synthetic substance; an oxidation product has been used in dermatological practice under the name of *pyraloxin*.

The two naphthols, $C_{10}H_7OH$, possess antiseptic properties; the benzoyl derivative of β-naphthol is employed under the name of *Benzonaphthol*. Tribromo-β-naphthol, m.p. 155°, is a disinfectant; the bromine atoms occupy the positions 1, 3, or 4 and 6 (Armstrong and Rossiter, *Proceedings of the Chemical Society*, 1891, 87).

A few more complicated phenolic compounds have been employed medicinally.

Purgen is the trade name for phenolphthaleïn—$C_{20}H_{14}O_4$—whilst *Aperitol* is a mixture of the alkyl and isovaleryl derivatives of phenolphthaleïn.

Phenol-Carboxylic-Acids.

Salicylic acid—$C_6H_4(OH)(COOH)$—is the most important of the hydroxy-aromatic acids, and was first obtained by the oxidation of saligenin and salicylaldehyde (Piria, *Annalen*, 1839, 30. 165). Subsequently it was found that the oil of different species of *Gaultheria* consisted chiefly of methyl salicylate (Löwig and Weidmann, *Pogg.* 1839, 46. 83; Köhler, *Ber.* 1879, 12. 246). The synthesis of salicylic acid was achieved by Kolbe and Lautemann (*Annalen*, 1860, 115. 201) by leading carbon dioxide over sodium phenoxide heated to 180°. Half the phenol distils over, the reaction following the course indicated by the equation—

$$2C_6H_5ONa + CO_2 = C_6H_4(ONa)(COONa) + C_6H_5OH.$$

Kolbe patented this process in 1877 (D.R.P. 426), protecting the use of the alkalies and alkaline earths.

R. Schmitt (*J. pr. Chem.* 1885, ii. 31. 397), explained the process as follows;—

$$C_6H_5ONa + CO_2 = C_6H_5 \cdot O \cdot CO \cdot ONa,$$
$$C_6H_5 \cdot O \cdot CO \cdot ONa = C_6H_4(OH)(COONa),$$
$$C_6H_4(OH)(COONa) + C_6H_5ONa = C_6H_5OH + C_6H_4(ONa)(COONa),$$

and patented a process (D.R.P. 29939) depending on the formation of the metallic phenyl carbonates which were then heated under pressure to 120°–140°, a salicylate being formed without the liberation of phenol. Other patents by Schmitt and von Heyden extend the reaction to substituted and homologous phenols, naphthols and hydroxyquinolines (D.R.PP. 31240 33635, 38052, 38742, 39662).

Hentschel (D.R.P. 24151) found that when diphenyl carbonate was heated to 200° in an indifferent atmosphere with sodium hydroxide or ethoxide, sodium salicylate was formed and phenol or phenetol distilled over.

This reaction was extended by Schering (D.R.P. 28985), who used sodium phenoxide, and by Hofmann and Schoetensock (D.R.P. 30172), who acted on sodium phenoxide directly with phosgene.

Marasse (D.R.PP. 73279 and 78708) heated phenol with potassium carbonate and carbon dioxide under pressure, and Schering (D.R.P. 133500) uses the mass obtained by fusion of sodium benzenesulphonate with caustic soda for conversion, as being especially suitable.

Various attempts have been made to oxidise orthocresol.

$$C_6H_4(OH)(CH_3) + 3O = H_2O + C_6H_4(OH)(COOH)$$

Lederer (D.R.P. 80747) protected the hydroxyl group by conversion into o-cresoxyacetic acid.

Friedländer and Löw-Beer (D.R.P. 170230) heat one part of o-cresol with five parts of caustic soda and five parts of copper oxide to 260°–270°, the excess of alkali protecting the hydroxyl group.

U. Pomilio (Brit. Pat. 103709) adds the cresol to 1 part of water and 5 to 6 parts of caustic soda, heats to 240°–260° and electrolyses with a current density at the anode (nickel, nickel-steel or iron) of 5–6 ampères per sq. dm.

The introduction of carboxyl by the use of carbon tetrachloride and soda (Reimer and Tiemann, *Ber.* 1876, 9. 1285) is technically useless in the original form; Zeltner and Landau (D.R.P. 258887) find that the reaction is much facilitated by the presence of copper or its salts.

Salicylic acid may also be obtained by heating o-chlorobenzoic acid with water and calcium hydroxide to 160°–170° (Boehringer, D.R.P. 288116).

Salicylic acid and its salts have been very extensively used, but not infrequently they give rise to gastric disturbances. By esterifying the carboxyl or acylating the hydroxyl, compounds are formed which pass the stomach more or less unchanged, but from which salicylic acid is liberated in the intestine.

The first artificial ester to be introduced was salol (Nencki and von Heyden, Brit. Pat. 8008 of 1886; D.R.PP. 38973, 43713, 46756, 57941, 68111, 70487, 70519), the preparation of this and other aryl salicylates being effected by heating salicylic acid with phenols or naphthols and phosphoryl chloride or phosphorus pentachloride.

$$2C_6H_4(OH)(COOH) + 2C_6H_5OH + POCl_3 = HPO_3 + 3HCl + 2C_6H_4(OH)(COOC_6H_5).$$

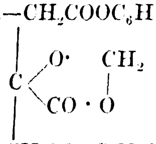
(For other processes, see Ernert, D.R.P. 62276; A.G. für Anilinf., D.R.P. 73452).

An objection to salol is that it yields phenol on hydrolysis, and a number of substances were introduced which give a less toxic compound than phenol when saponified.

Alphol—$C_6H_4(OH)(COOC_{10}H_7\alpha)$.
Aspirin—$C_6H_4(OCOCH_3)(COOH)$.

The British patent was subsequently rendered void, the compound having been first obtained by Gerhardt and recognised as acetylsalicylic acid by Kraut.

Benzosalin—$C_6H_4(OCOC_6H_5)(COOCH_3)$.
Betol—$C_6H_4(OH)(COOC_{10}H_7\beta)$.
Cordol—$C_6H_4(OH)(COOC_6H_2Br_3)$.
Diaspirin—$(CH_2 \cdot COOC_6H_4COOH)_2$.
Diplosal—$C_6H_4(OH)COOC_6H_4COOH$.
Glycosal—$C_6H_4(OH)COOC_3H_5(OH)_2$.
Methylaspirin—$C_6H_4(OCOCH_3)COOCH_3$.
Novaspirin—$CH_2COOC_6H_4COOH$



$CH_2COOC_6H_4COOH$.

Salacetol—$C_6H_4(OH)COOCH_2COCH_3$.
Salibromine—$C_6H_2Br_2(OH)COOCH_3$.
Vesipyrine—$C_6H_4(OCOCH_3)COOC_6H_5$.

Amongst salicylic compounds intended for external use, the following may be mentioned—

Mesotan—$C_6H_4(OH)COOCH_2OCH_3$,
Salit—$C_6H_4(OH)COOC_{10}H_{17}$,
Spirosal—$C_6H_4(OH)COOCH_2CH_2OH$, and
Salimenthol—$C_6H_4(OH)COOC_{10}H_{19}$.

(To be continued.)

ARTIFICIAL SILK INDUSTRY IN FRANCE.

The relative scarcity and high prices of silk and other textiles are at the bottom of a renewed interest that is being taken at present in the manufacture of the chemically-produced textile material known as artificial silk.

It was without any idea of filling a world demand that in 1855 Audemars, at Lausanne, Switzerland, took out his patent on a vegetable fibre for use in incandescent lamps. In 1884 the Count of Chardonnet discovered the collodion thread which he aspired to place alongside of silk in the textile world. But not until 1895 was it possible for the company which he founded to put on the market a thread which was denitrated and consequently less inflammable. Up to 1903 the new industry, interesting though it was, was not seriously regarded in the industrial world, but rather was considered in the light of an interesting novelty. In that year, however, the Société de la Viscose put on the market the artificial silk which until recently has been the last word in artificial textiles. It may be noted that this company is, in fact, a monopoly and controls the European market very effectively, selling or withholding its goods as it sees fit; only now has the widespread demand for chemical textiles encouraged lesser companies to undertake the manufacture of artificial silks.

On account of the substance which it employs (wood), the new industry has been enabled to adapt itself to any climate. Favoured by groups of Lyon merchants engaged in the French silk and textile industries, who did not hesitate to support the infant enterprise, it has become widely spread throughout the civilised world.

The production of artificial silk, which in 1902 was 2,000,000 kilos (4,408,000 pounds), rose successively to 5,000,000 kilos (11,020,000 pounds) in 1906, to 6,000,000 kilos (13,224,000 pounds) in 1912, and to 8,000,000 kilos (17,632,000 pounds) in 1914. Germany's production of this article is estimated at 5,000 kilos (11,020 pounds) daily; and France, when the new installations of machinery are completed and material more easily obtainable, will be capable of putting out some 4,000 kilos (8,816 pounds) per day. As in other French manufactures, the lack of fuel and the embarrassed transportation services are more serious obstacles than any lack of raw material. While it is impossible to estimate with exactness the total production for 1919, it was assuredly great, but far below the demand.

Progress was checked by the war, while at the same time the demand for the products of the industry was greatly augmented on account of the paucity of all textiles. In spite of the fact that viscose silk is extremely inflammable and cannot resist humidity, uses for it were numerous, during the war, to replace other materials; and it was even found possible to make use of it directly in war work. At Lyons, a cellulose-textile factory, serving as a plant for producing explosives, made

sacks of artificial silk to hold powder; and certain parts of the anti-asphyxiation masks used on the front were also made of this cloth.

It is worth noting that the increasing activity of the artificial-textile industry, far from coming into competition with that of the natural silk, coincides with and supplements the growth of the latter. The production of natural silk increased from 19,000,000 kilos (41,876,000 pounds) in 1904 to 23,000,000 kilos (50,692,000 pounds) in 1906, to 27,000,000 kilos (59,508,000 pounds) in 1912, and only dropped to 22,000,000 kilos (48,488,000 pounds) in 1914 because of the war. The difficulty experienced by natural-silk weavers in procuring sufficient material, and the top prices it commands, provide abundant proof that natural silk is more than ever in demand and has nothing to fear from what, at most, is a distant competitor. Viscose silk cannot be obtained in the really fine grades; its use is restricted, for the most part, to such uses as do not subject it to fire and water. In short, taking into consideration that natural silks cannot supply the market, the artificial silk supplements the natural product, but does not compete with it except in the lower grades.

According to a report prepared at the United States Consulate at Lyons, a renewed impetus was recently given to the use of chemical textiles by the invention of an entirely new process, the product of which is called silk cellulose. This new form of cloth is claimed to possess a brilliancy comparable to silk schappe, a remarkable solidity and durability, a touch similar to silk, and absolute imperviousness to water; at the same time it is no more endangered by fire than the ordinary natural silks. While the thread of the viscose silks is, of necessity, relatively coarse and thick, the new silk permits of making threads of considerable fineness, and is particularly remarkable for the quality of the velvets which can be made from it. The new process differs radically from the old processes. Instead of converting a thick liquid (the viscose) into thread, it appears that it is possible to preserve the wood fibres and convert them into a brilliant and solid cellulose. As a result of this there is obtained a greater molecular concentration and a regular geometric form in the elements that make up the thread; all of which, it is claimed, greatly increases the strength and durability of the cloth.

A large factory for the production of the new textile is being projected for large-scale commercial production in the Lyons district, where such materials as velvets, jerseys, satins, draperies, linings, and other silk goods will be woven. Although artificial silks can already be obtained at very advantageous prices as compared with natural silk, the inventor of the new process claims that his product will be able to reduce still further the cost of chemically-produced threads.

Despite the fact that for years to come the artificial textile may not compete with natural silk, yet the producers of the latter must eventually look for advances and inventions on the part of chemists that may ultimately remove the defects now so obvious in the viscose silks. What is most needed is ability to spin a much finer thread, which is at present extremely difficult on account of the air which is held in the coagulating bath in which the artificial threads are formed. Seven or eight years hence, when there has been time for a surplus of artificial silk to accumulate on the market, by reason of the establishment of new plants and increased production of other textiles, those whose interests are bound up in the artificial silk industry will be forced to bring about new developments in order to enable it to hold its place; at that time real competition may be looked for between natural and artificial silks.

The following data have been made public as technical means for determining the various sorts of artificial silks:—Sulphuric acid glycerinated: pure glycerine, 10 cubic centimetres; distilled water, 5 cubic centimetres; concentrated sulphuric acid, 15 cubic centimetres. Iodo-ioduret of potassium: iodide of potassium, 0·3 gramme; water, 30 cubic centimetres; iodine in excess. Chloro-ioduret of zinc: chloride of zinc, melted, 1·75 grammes; water, 30 cubic centimetres; iodine to saturation. Concentrated sulphuric acid; chromic acid, half saturated; solution of caustic potash at 40 per cent.; ammoniacal copper oxide: ammoniacal nickel oxide; a glycerinated and alkaline solution of copper. An acid solution of diphenylamine: diphenylamine, 1·57 grammes; concentrated sulphuric acid, 25 cubic centimetres.

The ammoniacal preparation of copper oxide is prepared by dissolving the copper oxide in ammonia in saturation, then passing through the solution a current of air from which the moisture has been removed by passing through a solution of caustic potash.

The ammoniacal solution of nickel oxide is prepared by dissolving 2 grammes of nickel sulphate (crystallised) in 30 grammes of water, precipitating the nickel by means of caustic soda, filtering, and then redissolving the precipitate in ammonia. The alkaline and glycerinated solution of copper is prepared by dissolving 3 grammes of copper sulphate in 30 cubic centimetres of water, with 1·75 grammes of pure glycerine, then adding enough caustic potash to precipitate the copper, and redissolving.

There are five kinds of artificial silk: Nitrated silks, collodion silks, the viscose silks, the acetate silks, and gelatine silks.

In calcinating a fragment of the silk in a small test tube, in the upper part of which has been placed a piece of red litmus-paper, the calcination, in the event of the silk being of the gelatine variety, will produce ammonia vapours which will turn the paper blue. There should be, further, the familiar odour of burnt horn. When calcinated, the four other kinds of silks emit vapours which turn the blue paper red.

The silk of the acetate variety, when treated

with glycerinated sulphuric acid, takes on a yellow colour with iodo-ioduret of potassium and also with the chloro-ioduret of zinc.

The silks of nitrocellulose, of the viscose silks, dissolve rapidly in sulphuric acid concentrated cold; the cellulose silks dissolve slowly. All three dissolve little by little in cold chromic acid, and rapidly if the acid be heated. The three, and the acetate silks as well, swell up in a solution of caustic potash; while in the same solution the gelatine silk dissolves rapidly and completely.

In the ammoniacal solution of copper oxide, the collodion and viscose silks begin by slowly swelling and then dissolving; while the acetate silks swell without dissolving, and the gelatine silk turns a bluish violet and does not dissolve.

With ammoniacal oxide of nickel the artificial silks swell without dissolving, except that the gelatine silk turns brown without dissolution or swelling.

The glycerinated and alkaline solution of copper does not have any effect on the artificial silks even after a prolonged boiling, excepting upon the gelatine silks, which are rapidly dissolved.

The solution of diphenylamine gives a pure blue colouration to the nitrocellulose silks alone; the colouration is most intense at the end of five minutes and fades little by little thereafter.

Care should, of course, be taken to make tests at the same time with silks of known varieties for purposes of checking and comparison. Should the silks have been dyed, the colour should be taken out with hydrosulphite.

VEGETABLE OILS IN PALESTINE.

The vegetable oils of Palestine are of two varieties—sesame and olive. In pre-war times both varieties were exported to a moderate extent, the preponderance being in favour of the olive oil.

During the Turkish *régime* sesame oil was used for lubricating purposes on the military railways, the result being that nearly the entire product had been used up before the British occupation. Another reason that helped to lessen the quantity of this oil was that, in view of the shortness of breadstuffs for the Army, the peasants were ordered to plant millet as a summer crop instead of the sesame. This error was later realised by the Turkish authorities when lubricating oil was much needed and unobtainable.

According to a report by the United States Consul at Jerusalem, the olive-oil industry suffered a severe setback during the war, from which it will take at least fifty years to recover. With the allied blockade of Turkish ports, wood for the railways had to be substituted for coal, and in Palestine the olive trees were required to bear the greater part of this substitution. The trees were cut down in the districts through which the railways ran, and it is estimated that half the olive trees were destroyed in this manner. Again, while retreating, the Turks mutilated the small branches of the olive trees for quick fuel. The destruction was further increased by the fact that most of the battles on this front took place in the olive-grove districts, and consequently the land around the trees could not be ploughed at the proper time and they will not yield advantageously, unless they are properly cultivated for at least two consecutive years. In addition to this war devastation, the locust plague in 1915 materially injured the trees.

It will be noted from the foregoing that the vegetable-oil industry in Palestine has suffered very severely during the last five years. At present these oils are very rare and their prices consequently greatly advanced.

In the manufacture of sesame oil the seeds are first soaked for a period and then beaten with large mauls in order to separate the outer shell from the kernel. Then the seeds are placed in a primitive oven, and later are ground between two flat stone discs turned by a camel or a mule, and the thick, pulpy fluid which flows from it is poured into a deep vat.

Of late years some European machines have been imported, but have not as yet, except to a very small extent, displaced the primitive method.

Sesame oil is used for cooking by almost the entire Jewish population, as the orthodox may not use butter fats with meat cooking. It is also generally used by the poor.

Most of the olives are now made into commercial oil—that is, for soap-making—and no great care is taken to turn out first-class table or salad oil. The olives when picked are poured into great piles and are left to wilt by overheating. This has the effect of producing the greatest possible quantity of oil which can be extracted by such a primitive method.

The olives are crushed by a large stone disc, which rotates on its edge. When crushed they are packed into goat-hair sacks or in special baskets and poured into an iron press. There are two types of such presses in use, one known as the French, and the other as the Greek. These machines were first imported from Europe, but latterly were extensively made in a German foundry at Jaffa. Since the occupation, a British firm has taken over the foundry and is again supplying these hand-power machines.

CORRESPONDENCE.

OIL RESOURCES OF THE BRITISH EMPIRE.

In reference to Sir John Cadman's exceedingly valuable paper on "The Oil Resources of the British Empire," I should like to say that it is impossible to foresee the future as regards mechanical inventions. Every practical engineer admits the great

advantages of oil fuel, not only for ships of war, but also for the great Atlantic liners. On the other hand, he would be a bold man who said that no substitute for oil fuel would ever be brought into practical use. May I suggest that the Low engine which was made and worked some years ago indicates the possibility that coal reduced to the condition of dust may some day be used for internal combustion engines, which might possibly consume less fuel per horse-power than the present marine engines where oil is used as a fuel for steam boilers?

May I also suggest the possibility that coal dust might be used on board ships as a fuel for steam boilers as a substitute for oil? I admit that the machinery for conveying the coal dust to the ship's boiler furnaces has yet to be invented, but a long-continued high price of oil and an increasing demand for fuel that will do the work that is now done by fuel oil is likely to lead to inventions for utilising coal of which there are such abundant stores.

ARNOLD LUPTON.

With regard to the above communication, it is understood that no definite results so far arrived at are calculated to remove such a suggested substitute from the region of doubt, or to encourage the hope that we are within measurable distance of the replacement of oil fuel by coal dust. It has been demonstrated, however, that a fuel oil and coal dust can be used in combination. In a most valuable lecture delivered by Sir Frederick W. Black, K.C.B., B.A. (Lond.), at a meeting of the Institution of Petroleum Technologists held at the Crystal Palace on June 3rd, the lecturer stated that another hopeful direction for economy of heavy oil fuel lay in the combination of oil with finely pulverised coal, in what was known as colloidal form. An admixture of coal dust up to about 33 per cent. had been found admissible for marine purposes, and up to 50 per cent. for use on land. Practical and technical difficulties still had to be overcome in keeping the coal in prolonged suspension in the oil in ships' tanks, and when, in the near future, as appeared probable, those difficulties were finally surmounted, the area of use of liquid fuel in ships would have been widely extended.

GENERAL NOTES.

A PASSAVENT CARPET.—Mr. A. F. Kendrick, of the Department of Textiles, Victoria and Albert Museum, sends the following account of a carpet made by Passavent, of Exeter (to whom the Society granted a premium in 1758), which was sold at Christie's for 750 guineas on June 29th. It now measures 15 ft. by 12 ft. 5 in. The ground is pale blue, with a pattern of acanthus foliage, baskets of flowers, garlands and parrots. There is an outer *contrefond* in black. In the middle of the carpet is a realistic representation of a dog on a cushion. The border is pale blue, with a pattern of shells, masks, acanthus foliage and floral stems. The workmanship is excellent, the surface being very level and smooth. The colours were good, and are still, for the most part, finely preserved. Along one border the inscription "EXON: 1757" is knotted in two-inch letters of a pale brown colour. In regard to the technique, the warp is of white wool, lying in two levels. Every twentieth warp is brown—probably to facilitate counting. The weft is of coloured wool. There are two shoots after each row of knots. The pile is of wool. A knot, known as the "Ghiordes" knot, is the one used. This knot is the most generally found of all those used in the East. There are about eighty knots to the square inch.

FUEL FOR MOTOR TRANSPORT.—The Fuel Research Board of the Department of Scientific and Industrial Research have prepared an interim memorandum on fuel for motor transport, which has been published by H.M. Stationery Office for the Department. The memorandum deals chiefly with the possibility of the substitution of power alcohol for petrol as a motor fuel, and is divided into three sections: (1) Historical; (2) The Present Position of Power Alcohol; (3) Alternative Motor Fuels. Copies of the memorandum, price 3d., may be obtained through any bookseller, or directly from H.M. Stationery Office.

BRITISH EMPIRE EXHIBITION.—In the House of Commons on August 8th, Mr. Kellaway (Overseas Trade Department) moved: "That it is expedient to authorise the payment out of moneys provided by Parliament of any sums not exceeding £100,000 required for the fulfilment of any guarantee against loss resulting from the holding of a British Empire Exhibition given by the Board of Trade." He explained that the idea of the exhibition originated with the late Lord Strathcona, that the guarantee would only become operative if a guarantee of £500,000 was forthcoming from private sources, and that the money would not in any case be payable until 1923. After a discussion, the motion was agreed to.

IMPROVED MINE RESCUE METHODS AND APPARATUS.—The Mine Rescue Apparatus Research Committee of the Department of Scientific and Industrial Research have presented their second report to the Advisory Council of the Department, on whose recommendation it has now been published. The work described in the report relates chiefly to experimental results obtained during the last two years since the publication of the Committee's first report, and to the description of new or improved mine rescue methods and apparatus which are the outcome of the investigation. The report is divided into four parts:— I. Physiological considerations and experiments; II. Deaths due to rescue apparatus; III. Approval of mine rescue apparatus; IV. Miscellaneous; and two appendices are included, I. The Briggs' compressed oxygen mine rescue apparatus; II. Fitness testing with the ergometer. Copies of both the first and second report of the Committee (price 1s. 9d., by post 1s. 11d., and 2s., by post 2s. 2d. respectively), may be obtained directly from H.M. Stationery Office.

Journal of the Royal Society of Arts.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

SYNTHETIC DRUGS.

By JOHN THEODORE HEWITT, M.A., D.Sc., Ph.D., F.R.S.,

Emeritus Professor of Chemistry, East London College.

Lecture II.—Delivered December 8th, 1919.

THE AROMATIC SERIES.

PHENOLS.

(Continued from page 635.)

Aromatic amines and their derivatives.

Aniline and homologous amines have a distinct effect in lowering the temperature, but their use in an unmodified condition is rendered impossible by their toxic properties. The latter are twofold: the motor centres of the midbrain are paralysed and vertigo results, and, in addition, the hæmoglobin is attacked. The higher homologues differ qualitatively, and the position of the substituent groups makes a considerable difference. Metatoluidine closely resembles aniline. Ortho- and para-toluidine are much milder in their effects, whilst in benzylamine the antipyretic action nearly disappears.

By acylating the aromatic amines, substances are obtained which are more resistant in the circulation, but which still possess antipyretic properties. The observation that acetanilide is oxidised in the body and hydroxyl introduced in the para position, and further, that para-aminophenol, whilst a strong antipyretic, is much less toxic than aniline, points to the use of a derivative of para-aminophenol protected in such a way as not to attack the red blood corpuscles. Acetylation of the amino-group does something, but even better results are obtained if the hydroxyl group is ethylated; the resulting compound, *p*-ethoxyacetanilide, commonly known as phenacetin, being a much used substance.

Paramethoxyacetanilide, Methacetin, is less satisfactory, though it has a maximum antipyretic action; the higher alkyl groups render the molecule too inactive.

A number of substituted anilides have been introduced as antipyretics under trade names—

Antifebrin—$C_6H_5NHCOCH_3$.

Exalgin—$C_6H_5N(CH_3)COCH_3$.

Cosaprin—$C_6H_5(NHCOCH_3)SO_3Na$.

Amygdophenin—
$C_2H_5OC_6H_4NH\cdot CO\cdot CHOH\cdot C_6H_5$.

Apolysin—
$C_2H_5OC_6H_4\cdot NH\cdot CO\cdot C_3H_5(COOH)_2$.

Eupyrine—
$C_2H_5OC_6H_4\cdot NHCO\cdot C_6H_3(OCOOC_2H_5)(OCH_3)$.

Kyrofin—$C_2H_5O\cdot C_6H_4\cdot NH\cdot COCH_2OCH_3$.

Lactophenine—
$C_2H_5O\cdot C_6H_4\cdot NH\cdot CO\cdot CHOH\cdot CH_3$.

Malakin—$C_2H_5O\cdot C_6H_4\cdot NH\cdot CO\cdot C_6H_4\cdot OH$.

Phenocoll—
$C_2H_5O\cdot C_6H_4\cdot NH\cdot CO\cdot CH_2\cdot NH_2, HCl$.

Pyrantin— $\begin{matrix}CH_2CO\\ |\\ CH_2CO\end{matrix}\!\!>N\cdot C_6H_4\cdot OC_2H_5$.

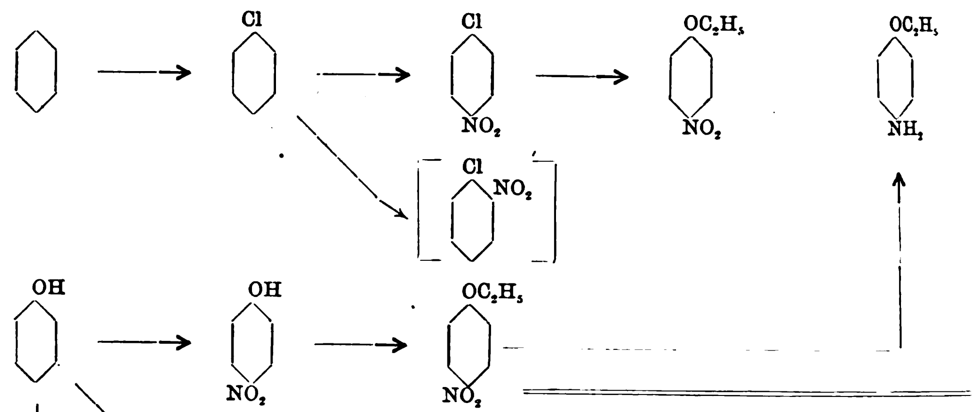
Salophen—
$C_6H_4(OH)COO\cdot C_6H_4\cdot NH\cdot CO\cdot CH_3$.

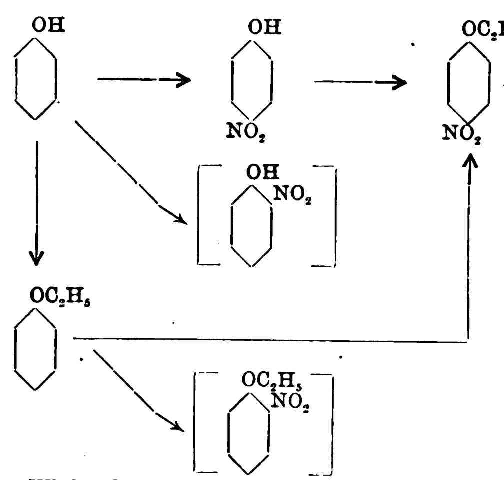
Triphenine—$C_2H_5O\cdot C_6H_4\cdot NH\cdot CO\cdot C_2H_5$.

Thermodine—
$C_2H_5O\cdot C_6H_4N(COOC_2H_5)(COCH_3)$.

Valerydine—$C_2H_5O\cdot C_6H_4\cdot NH\cdot CO\cdot C_4H_9$.

Regarding the preparation of substances of this type, we may confine ourselves to phenacetin and the phenetidine from which it is derived by acetylation. Whether we start with benzene or phenol, we must at some stage obtain a mixture of ortho and para isomerides, and discard the former.





Whilst the route appears shorter if we start with phenol, the separation of *p*-nitrophenol is so troublesome that it is preferable to make it from *p*-nitroacetanilide by alkaline hydrolysis. In nitrating phenetole, the production of dinitrophenetole (Cahours, *Annalen*, 1850, 74. 315) must be avoided, so that an adaptation of Willgerodt's process (*Ber.* 1882, 15. 1002), viz. boiling *p*-chloronitrobenzene with water, alcohol and caustic potash appears most promising.

Aromatic Acids.

Many derivatives of benzoic acid and amino-alcohols have been introduced as local anæsthetics. Amongst naturally occurring products we have cocaine, an alkaloid found together with ecgonine and other derivatives in the leaves of *Erythroxylon coca.* Atropine, which may be hydrolysed to tropine and tropic acid, is closely related, in fact all these compounds are derivatives of tropine itself. Their relationships are shown in the following table:—

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CHOH
|    |    |
CH₂—CH——CH₂
```
Tropine (not mydriatic).

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CH·OCO·CH·C₆H₅
|    |    |      |
CH₂—CH——CH₂    CH₂OH
```
Atropine (mydriatic).

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CHOH
|    |    |
CH₂—CH——CH·COOH
```
Ecgonine (not anæsthetic).

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CHOH
|    |    |
CH₂—CH——CH·COOCH₃
```
Methylecgonine (not anæsthetic).

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CH·OCOC₆H₅
|    |    |
CH₂—CH——CH·COOCH₃
```
Cocaine (anæsthetic)

```
CH₂—CH——CH₂
|    |    |
|   NCH₃ CH·OCO·CH : CH·C₆H₅
|    |    |
CH₂—CH——CH·COOCH₃
```
Methylcinnamylecgonine (not anæsthetic).

We can, in a sense, include cocaine as a synthetic drug, since the alkaloids of coca. which show no anæsthetic action, may be utilised. Ecgonine can be produced, and then methylated and benzoylated. It may be remembered that the benzoyl derivatives of morphine, quinine, etc., behave to some extent as local anæsthetics.

It is desirable that a local anæsthetic should stand boiling in solution. Cocaine is prone to hydrolyse under these conditions, and its toxicity and action as an irritant are also against it.

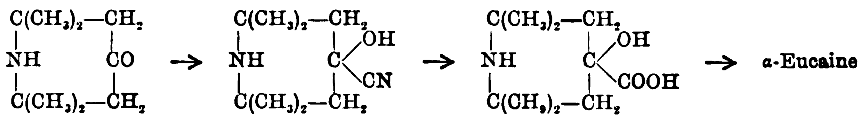
Some of the synthetic drugs, with constitutions resembling that of cocaine, are more reliable in these respects.

a-Eucaine—$C_{19}H_{27}O_4N$—

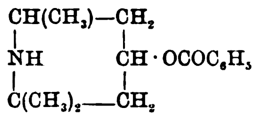
```
CH₃—C(CH₃)—CH₂
     |       |  /OCOC₆H₅
     NH      C<
     |       |  \COOCH₃
CH₃—C(CH₃)—CH₂
```

is less toxic than cocaine and its solutions can be sterilised by boiling; unfortunately it is irritant.

Ammonia is condensed with acetone to diacetoneamine, and the latter with more acetone to triacetoneamine. From this compound the cyanhydrin is formed which is hydrolysed to an α-hydroxy acid, the latter being methylated and benzoylated.



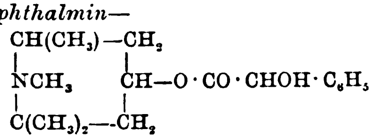
β-Eucaine—$C_{15}H_{21}O_2N$—is official as *Benzamine lactate*; its structure is given by the formula—



In synthesising the compound, diacetoneamine is condensed with aldehyde (or paraldehyde) to give vinyl-diacetoneamine, and this is reduced to the corresponding secondary alcohol. Obtained in this manner, it melts at 123°. The product is really a mixture of stereoisomerides melting at 137°–138° and 160°–161° respectively. It is from the labile (*cis*-) form that the active derivative is obtained.

The effect as a local anæsthetic would appear to depend to some extent on the benzoyl group, for in

Euphthalmin—



one has a substance which possesses mydriatic but not anæsthetic properties.

The essential groups in the local anæsthetics considered appear to be a secondary or tertiary amino-group, and a benzoylated secondary or tertiary carbinol. The substances so far considered contain the amino- and carbinol-groups as members of a 6-ring, but is this 6-membered ring essential? Fourneau (*Compt. rend.* 1904, 138. i. 766) tried benzoylating open-chain amino-alcohols, and found that certain of these could act as local anæsthetics.

Stovaine — $CH_3\cdot C(C_2H_5)(OCOC_6H_5)CH_2\cdot N(CH_3)_2$,HCl—was obtained by Fourneau by acting on dimethylaminoacetone with ethyl magnesium bromide; the resulting tertiary alcohol was benzoylated.

Alypin—$(CH_3)_2N\cdot CH_2\cdot C(C_2H_5)(OCOC_6H_5)\cdot CH_2\cdot N(CH_3)_2$, HCl—differs from stovaine in containing an extra dimethylamino-group (D.R.P. 173610).

Novocaine—$NH_2\cdot C_6H_4\cdot COO\cdot CH_2CH_2\cdot N\cdot(C_2H_5)_2$, HCl (compare, *Annalen*, 1910, 371. 125)—has met with much success. Diethylamine and ethylene chlorhydrin react to give diethylamino-ethyl alcohol, and the latter compound gives a *p*-nitrobenzoic ester when treated with *p*-nitrobenzoyl chloride. By reduction of the nitro-group, novocaine is obtained.

A modification (D.R.P. 180292) consists in the reduction of the azobenzoic alkamine ester which can be obtained either from azobenzoic acid or azobenzoyl chloride.

Anæsthesin — $NH_2C_6H_4COOC_2H_5$ — is even simpler in constitution. *Subcutin* is its phenol-*p*-sulphonate.

Propæsin and *Cycloform* are the corresponding propyl and isobutyl esters of *p*-aminobenzoic acid.

Nirvanin is $C_6H_3(\overset{1}{C}OOCH_3)(\overset{2}{O}H)(NH\overset{3}{C}OCH_2N)(C_2H_5)_2$.

Orthoform is methyl-*p*-amino-*m*-hydroxybenzoate, in *Orthoform new*, the hydroxyl and amino groups are interchanged.

Holocaine—$CH_3\cdot C\left\langle\begin{matrix} N\cdot C_6H_4OC_2H_5 \\ NH\cdot C_6H_4OC_2H_5\end{matrix}\right.$, HCl—is somewhat toxic.

Acoine — $C\left\langle\begin{matrix} N\cdot C_6H_4OC_2H_5 \\ (NH\cdot C_6H_4OCH_3)_2\end{matrix}\right.$, HCl—is a derivative of guanidine, and apparently less toxic than cocaine.

Lecture III.—Delivered December 15th, 1919.

Quinoline Derivatives.

The recognition of the quinoline nucleus in quinine drew attention more than thirty years ago to the possibility of using quinoline derivatives as drugs. Several of these possess antipyretic properties; in other respects they are unsatisfactory, and interest in them is chiefly historical.

Kairoline.—This name was given to the acid sulphates of tetrahydroethylquinoline (Kairoline A), or tetrahydromethylquinoline (Kairoline B). These bases were obtained by Koenigs

and Hofmann by the reduction of ethyl or methyl quinolinium salts.

Kairine (O. Fischer, D.R.P. 21150) was obtained by reduction of *o*-hydroxyquinoline and subsequent alkylation.

Thallin is strongly antipyretic but toxic.

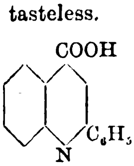
O-*Hydroxyquinoline* has its uses as a disinfectant. *Chinosol*, which was supposed to be potassium hydroxyquinoline-sulphonate, turned out to be a mixture of the sulphates of the base and potassium.

Oxychinaseptol or *Diaphtherin* is the phenol-*o*-sulphonate of *o*-hydroxyquinoline.

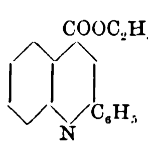
Atophan—2 - Phenylquinoline - 4 - carboxylic acid, m.p. 208°-209°—promotes the excretion of uric acid, and is consequently used in the treatment of gout and acute articular rheumatism.

Acitrin—m.p. 60°-61°—is the ethyl ester of the preceding acid. Its action is similar, but the excretion of uric acid begins later.

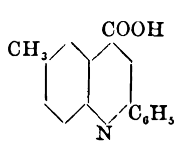
Paratophan and *Novatophan* are higher homologues of the above; *Isatophan* is a methoxy derivative of atophan. Whilst atophan is bitter, isatophan and novatophan are tasteless.



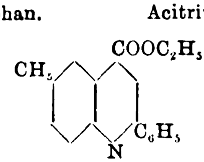
Atophan.



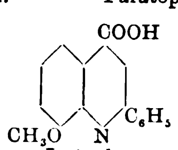
Acitrin.



Paratophan.



Novatophan.



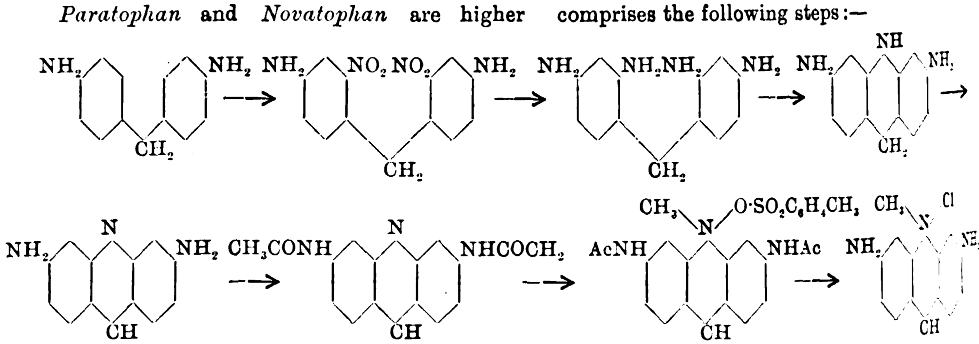
Isatophan.

Acridine Derivatives.

The derivatives of 2:8–diaminoacridine have received considerable attention in the last two years on account of the properties of 10-methyl-2:8-diaminoacridinium chloride. Benda (*Ber.* 1912, 45. 1787) first prepared this compound at Ehrlich's suggestion, and experiments on mice showed that it possessed strong trypanocidal action; it was in fact three times as active as the corresponding compound obtained from acridine yellow (3:7-dimethyl-2:8-diaminoacridine). It was also tried on man and found to produce a distinct effect in sleeping sickness.

Further interest in the compound (Trypaflavine, Flavine, Acriflavine, Proflavine) was aroused by the observations of Browning, Gulbransen, Kennaway, and Thornton (*British Medical Journal*, 1917, i. 73; see also *Proceedings of the Royal Society*, 1918 (B), 90. 136). Most antiseptics act more powerfully in water than in blood serum, but the reverse holds for Flavine, *Staphyllococcus aureus* being killed at a dilution of 1 in 20,000 of water containing 0·7 per cent. of peptone, but at 1 in 200,000 in blood serum. For *Bacillus coli* the respective figures are 1:1,300 and 1:100,000. Flavine has, moreover, a low toxicity.

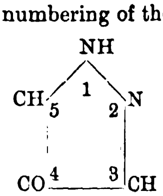
Benda's method of preparing the compound comprises the following steps:—



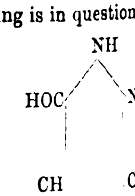
The successful preparation of diaminoacridine from *m*-phenylenediamine and formic acid has been claimed recently (Poulenc Frères & Meyer. Brit. Pat. 137214).

Pyrazolone Derivatives.

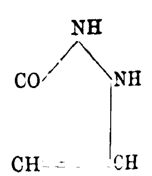
Of the pyrazolone derivatives the most important is *antipyrine* or phenazone. The pyrazolone compounds exhibit tautomerism; this has to be kept in mind, especially when the numbering of the ring is in question.



I.

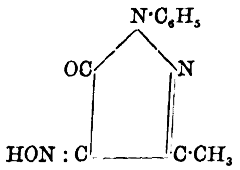


II.

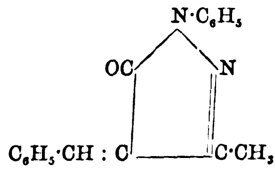


III.

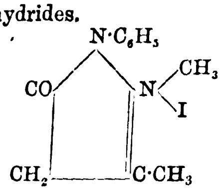
The preparation of phenylmethylpyrazolone leads to a formula for the substance corresponding with Constitution I., and it appears to agree well with the formation of isonitroso and benzylidene compounds which may be formulated as



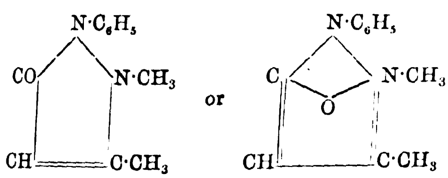
and



respectively. The solubility in alkalies corresponds better with Structure II., whilst the anhydro-bases (*e.g.* antipyrine) obtained by the addition of alkyl halides and removal of the elements of hydrogen halide agree either with Structure III. or must be formulated as internal anhydrides.



Antipyrine hydrodide.



Antipyrine.

1-Phenyl-3-methyl-5-pyrazolone was obtained by Knorr by the action of phenylhydrazine on ethyl acetoacetate (D.R.P. 26429; *Ber.* 1883, 16. 2597; 1884, 17. 546; 1885, 18. 311, 931, 2256; *Annalen*, 1887, 238. 137).

The compound, which has the formula $C_{10}H_{10}ON_2$, and is soluble in acids and alkalies, was at first taken for a derivative of quinoline; subsequently it was recognised as a pyrazole derivative.

Methyl iodide, in presence of sodium methoxide gives a dimethyl-derivative identical with that obtained by the condensation of phenylhydrazine with dimethylacetoacetic ester.

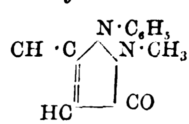
Phenazone, Antipyrine.—In the absence of alkalies, alkyl halides attach themselves to the second nitrogen atom, which thereby becomes quinquevalent. The preparation of antipyrine as originally described consisted in heating equal weights of phenylmethylpyrazolone, methyl iodide and methyl alcohol under pressure to 100°, decolorising the reaction product with sulphurous acid, distilling off the alcohol and separating the base as a heavy oil by the addition of strong caustic soda solution; by crystallisation from ether it was obtained with a melting-point of 113°. It is understood that methyl bromide is used on the manufacturing scale, and Knorr has also obtained antipyrine by the condensation of acetoacetic ester with *symm*-methyl-phenylhydrazine.

Numerous modifications have been made in the synthesis; phenylhydrazine hydrochloride can be used in place of the free base (Michael, *Amer. C.J.* 1892, 14. 517), and acetoacetanilide in place of the ester (Knorr. *Ber.* 1894, 27. 1175).

1-Phenyl-3-methyl-5-ethoxypyrazole when hydrolysed gives phenylmethylpyrazolone, whilst it is converted into antipyrine by methylation and treatment with alkali (D.R.PP. 72824 and 84142).

Reduction of benzeneazo-crotonic ester gives phenylmethylpyrazolone (Bender, *Ber.* 1887, 20. 2749), and numerous variations of these reactions are known. Crotonic acid itself condenses with phenylhydrazine to furnish phenylmethylpyrazolidone (Knorr, *Ber.* 1892, 25. 762), which may be oxidised by ferric chloride to the pyrazolone, but the corresponding dihydroantipyrine cannot be oxidised to antipyrine.

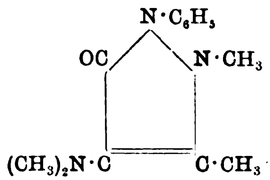
Phenylhydrazine and β-chloro-crotonic acid give a phenylmethylpyrazolone (D.R.P. 64444); on methylation an isoantipyrine (poisonous) is produced, probably



The esters of tetrolic acid also condense to form phenylmethylpyrazolone (Krauth, D.R.P. 77174).

Another way of preparing phenylmethylpyrazolone is from acetone-dicarboxylic acid (von Pechmann, *Annalen*, 1891, 261. 172; D.R.PP. 32245, 32277), the resulting phenylpyrazolone-acetic acid loses carbon dioxide on heating.

Pyramidone.—This compound is 1-phenyl-2, 3-dimethyl-4-dimethylamino-5-pyrazolone.



According to Filehne its physiological action resembles that of antipyrine, but it is three times as powerful, its action develops more slowly and lasts longer.

Antipyrine is converted into its nitroso-derivative which is reduced and the amino-antipyrine isolated as its benzylidene derivative. The latter is decomposed by hydrochloric acid, the benzaldehyde removed by ether and the amino-group subsequently methylated (D.R.PP. 90959, 97011, 97382).

To avoid the formation of quaternary ammonium compounds, Meister, Lucius and Brüning form the diacetic acid of the amino-antipyrine, $C_{11}H_{11}ON_2 \cdot N(CH_2COOH)_2$, and subsequently remove two molecules of carbon dioxide by heating with dilute acids to 130°–140°.

The Société Chimique de l'Avanchet (D.R.P. 203753) achieves the same result by making use of the reaction expressed by the equation

$$C_{11}H_{11}ON_2 \cdot NH_2 + NO \cdot N(CH_3)_2 = N_2 + H_2O + C_{11}H_{11}ON_2 \cdot N(CH_3)_2.$$

Pyramidone may also be obtained from 4-Bromoantipyrine by the action of dimethylamine and methods for stabilising the amino-group during methylation are described by Meister, Lucius and Brüning (D.R.P. 189842) and Scheitlin (D.R.P. 199844).

Modified Alkaloids.

The valuable therapeutic properties of many alkaloids render them indispensable, since in many cases no suitable synthetic substitutes have been prepared. Thus the desirable properties of quinine and morphine are not found fully associated with any artificial drug. Such natural compounds, therefore, remain essential, though they may have drawbacks as well as advantages, and it is a matter for the chemist to make derivatives eliminating the disadvantages whilst preserving the valuable properties.

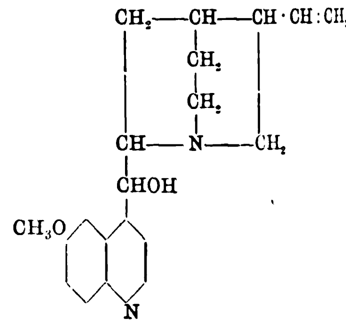
A few examples of modified alkaloids will give an idea of the methods adopted in making constitutional variations.

Quinine Derivatives.

Quinine—$C_{20}H_{24}O_2N_2$—occurs in cinchona bark associated with several other alkaloids, amongst which cinchonine may be specially mentioned. Cuprea bark also contains quinine and an alkaloid cupreine, structurally closely related to quinine and cinchonine.

Cinchonine—$C_{19}H_{22}ON_2$.
Cupreine—$C_{19}H_{21}O(OH)N_2$.
Quinine—$C_{19}H_{21}O(OCH_3)N_2$.

A probable structure for quinine is—



the methoxyl group being replaced by hydroxyl in the case of cupreine and by hydrogen in the case of cinchonine.

The bitter and lasting taste of quinine is a disadvantage, and many attempts have been made to get over the difficulty. One method is to convert quinine into its tannate. This is nearly tasteless in virtue of its very slight solubility. At the same time the sparing solubility involves uncertainty as to the action of the drug, which is not split into its components before reaching the intestine. A more ingenious and effective way is to alter some portion of the quinine molecule so as to give a tasteless product which can get beyond the mouth and subsequently be hydrolysed in the stomach or intestine with regeneration of the alkaloid. The alcoholic hydroxyl group gives an opportunity, and by its esterification several nearly tasteless quinine derivatives have been prepared.

Zimmer and Co. applied for a patent in 1895 (D.R.P. 90848) to protect the conversion of quinine into the chlorocarbonate, the anhydrous base being brought into reaction with phosgene in benzene solution. The following equation is given to explain the reaction:—

$$COCl_2 + 2C_{20}H_{24}O_2N_2 = C_{20}H_{23}ON_2(OCOCl) + C_{20}H_{24}O_2N_2, HCl.$$

No specific action is attributed to the drug: its advantage is simply its tastelessness. Further patents dealing with the reaction and

extending it to other cinchona alkaloids were taken (D.R.PP. 93698, 118122), whilst D.R.P. 105666 varies the reaction so as to give the carbonic ester of quinine.

$$COCl_2 + 4C_{20}H_{24}O_2N_2 = CO(O{\cdot}C_{20}H_{23}ON_2)_2 + 2C_{20}H_{24}O_2N_2, HCl.$$

This product was introduced as *Aristoquinine.* It is practically tasteless, and hydrolyses to quinine and carbonic acid. (See also D.R.PP. 117095, 134307, 134308.)

Probably the greatest improvement in the direction of making a practically tasteless but easily hydrolysed quinine compound is connected with the conversion of quinine into carbalkyloxy-compounds such as "quinine ethyl carbonate" or euquinine (D.R.PP. 91370, 118352, 123748).

Quinine ethyl carbonate is stated by Zimmer to be obtainable by the action of ethyl chlorocarbonate on two molecules of quinine.

$$2C_{20}H_{24}O_2N_2 + ClCO_2C_2H_5 = C_2OH_{24}O_2N_2, HCl + C_{20}H_{23}(OCO_2C_2H_5)CN_2.$$

The liberated hydrochloric acid may also be fixed by caustic soda or pyridine.

Otherwise, the ethyl chlorocarbonate is brought to reaction with a dry quinine salt.

Various methods of covering the hydroxyl group and eliminating the bitter taste have been proposed, such as the formation of quinine urethanes (Zimmer, D.R.P. 109259).

$$C_{20}H_{23}(OH)ON_2 + O : C : N{\cdot}X = C_{20}H_{23}(O{\cdot}CO{\cdot}NHX)ON_2.$$

By heating with aromatic esters, esters of quinine are obtained. Saloquinine, the salicyl ester of the alkaloid, is obtained by heating quinine with salol, phenol being eliminated (D.R.PP. 128116, 129452, 131723, 137207). Auroquine is the *p*-aminobenzoic ester of quinine.

Acetylation may be resorted to (Knoll and Co., D.R.PP. 131595, 200063), whilst "Insipin" is the diquinine ester of diglycollic acid (Boehringer, D.R.P. 237450).

Various reduction products of quinine have been described, obtained by the action of hydrogen in presence of a catalyst (Zimmer, D.R.PP. 234137, 252,136). Hydroquinine is stated to be superior to quinine in its action on trypanosomes.

Morphine Derivatives.

Morphine—$C_{17}H_{19}O_3N$—is one of the chief alkaloids contained in opium. It is associated with papaverine, codeine, thebaine, narcotine, etc. Without going at length into the constitution of these alkaloids, it may be noted that of the three oxygen atoms in morphine, one belongs to an alcoholic, the other to a phenolic hydroxyl, whilst the third atom of oxygen forms a member of a closed ring, which also contains a tertiary nitrogen atom in the form $\rangle$N. CH_3.

Codeine—$C_{17}H_{18}(OCH_3)O_2N$—is morphine methylated on the phenolic hydroxyl. Knoll (D.R.P. 39887) patented the preparation of codeine and ethyl-morphine by boiling morphine in alcoholic solution with alkali and an alkaline methyl or ethyl sulphate. The methylation of morphine may also be effected by the use of diazomethane (D.R.PP. 92789, 95644, 96145), or alkyl sulphates (D.R.P. 102634), phosphates (D.R.P. 107225), nitrates (D.R.P. 108075), and sulphites (D.R.P. 214783).

Dionine is the hydrochloride of ethyl-morphine, and

Peronine (Mering, D.R.P. 91813) the hydrochloride of benzyl-morphine.

Diamorphine (Heroine) is official; it is diacetylmorphine.

"The object in forming these bodies has been to produce a sedative resembling morphine, which will relieve pain without having the depressing action of morphine on the respiratory centre.

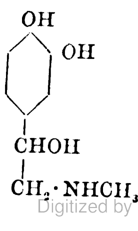
"All three are employed to diminish useless cough and alleviate other forms of peripheral irritation." (Dixon, "A Manual of Pharmacology," 4th Edition, p. 139.)

Apomorphine is official as its hydrochloride—$C_{17}H_{17}O_2N,HCl$; it is obtained by the action of hydrochloric acid on morphine.

Morphosan—$C_{17}H_{19}O_3N(CH_3)Br + H_2O$—is a different type of compound; it has been used as a sedative and hypnotic.

Adrenaline.—Before leaving alkaloidal substances, we may mention adrenaline (epinephrine, suprarenine), a basic substance which is the active principle of the suprarenal gland.

It was first isolated in an impure condition by Abel and Crawford in 1897, and Aldrich (*American Journal of Physiology*, 1901, 5. 457) found that its formula was $C_9H_{13}O_3N$. This was confirmed by Jowett (*Transactions of the Chemical Society*, 1904, 85, 192), who assigned to it the constitution—



This formula was confirmed by Friedmann (*Beitr. chem. Physiol. Path.* 1904, 6. 92; Pauly, *Ber.* 1904, 37. 1387; Stolz, *ibid.* 4149).

Compounds nearly allied to adrenaline in constitution have been synthesised by Barger and Jowett (*Transactions of the Chemical Society*, 1905, 87. 967) and Dakin (*Proceedings of the Royal Society*, B. 76. 491, 498).

An artificial drug, having much the same action as adrenaline, has been introduced by Burroughs and Wellcome under the name of *Ergamine;* a recent technical synthesis of adrenaline may be noted (Nagai, Brit. Pat. 118298).

Organo-metallic Compounds.

Metallic salts of organic acids are largely employed in medicine, frequently with the object of combining the specific actions of the base and acid. But there is a further class of compounds in which metal is directly combined with carbon, and these compounds are frequently of very considerable use.

In considering these substances, it may be easier if we follow the periodic classification of the elements, including certain compounds of non-metallic elements.

Copper.

Copper salts have but limited application, and no compounds are used in which copper is directly attached to carbon.

Silver.

A large number of silver preparations have been introduced, but it is doubtful whether in any of them the silver is in real organic combination, *i.e.* directly attached to carbon. In the greater number, silver or a silver compound is held in colloidal solution. The bactericidal properties of the silver remain unimpaired, but the preparations have not the irritating effect of silver nitrate.

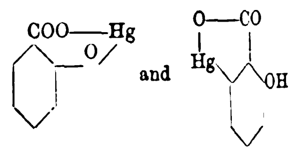
Mercury.

Mercury is an element which readily forms organo-metallic derivatives. Many of these are of considerable value, whilst they have great chemical interest, in that mercury salts directly attack organic compounds, hydrogen being eliminated and the mercury attaching itself directly to carbon.

For a mercury compound to be really useful, it should not precipitate protein substances, and should be capable of being injected subcutaneously or intramuscularly with a minimum of pain; at the same time it should dissolve quickly in water. Colloidal mercury (Hyrgol), the compounds obtained by the action of phenols on mercury nitrate (D.R.P. 48539), and the mercury derivative of formamide (O. Liebreich, 1890), have found but limited application.

Other amides and amino-acids have been used for the preparation of mercury compounds, *e.g.* glycine (v. Mering), succinimide (Vollert), and asparagin (Ludwig).

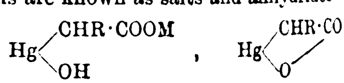
So-called basic mercury salicylate (Hydrargyrum Salicylicum) has found considerable application; of the two formulæ



the latter, with mercury in organic combination, is the more probable. Though it is insoluble in water, it forms soluble salts with the alkaline chlorides.

Easily soluble compounds (*e.g.* Asurol) with amino-aliphatic acids have also been prepared (D.R.PP. 224435, 224864), as well as with various imides of acid function (barbituric and parabanic acids, D.R.P. 227391).

Mercuriated derivatives of the aliphatic acids may be prepared by the action of mercuric oxide on malonic ester, hydrolysis and elimination of carbon dioxide; the resulting mercuriated acids are known as salts and anhydrides



(Schöller and Schrauth, *Ber.* 1908, 41. 2087. D.R.PP. 208634, 213371, 234054).

1. *Afridol.*—Sodium salt of Hydroxymercuric-o-toluic acid.

2. *Hydrargyrol* is a mercury derivative of phenol-*p*-sulphonic acid. *Asterol* is a double compound with ammonium tartrate.

3. *Hermophenyl* (Lumière and Chavrottier) is obtained by digesting an alkaline solution of phenoldisulphonic acid with mercuric oxide.

4. *Phenegol*, *Kresegol* and *Thymegol* are derivatives of o-nitro-phenol and cresol- and thymol-sulphonic acids.

5. It is possible to obtain organic derivatives containing both mercury and iodine; thus *Anogon* is the mercurous salt of 2 : 6-diiodo-phenol-4-sulphonic acid.

Aluminium.

Various salts of aluminium have been introduced as astringents; they are of no particular interest.

Alformin.—Basic aluminium formate.

Alsol.—An acetotartrate.

Alumnol.—Aluminium napthol-sulphonate.

Boral.—Alumina and boric acid dissolved in formic acid.

Cutol.—Alumina with boric and tannic acids.

Salumines.—Salicylates of aluminium.

Sozal.—Aluminium phenol-*p*-sulphonate.

Cerium.

Phenolic compounds react with cerium salts to give cerphenols, cerguaiacol, cernaphthol, etc. According to Schering (D.R.P. 214782) these compounds have a greater disinfectant power than the phenols themselves, and are, at the same time, less toxic.

Phosphorus.

Compounds in which phosphorus is in true organic combination have not found organic medicinal application. On the other hand, the glycero-phosphates, on account of their close relationship to lecithin, have been used extensively. Glycerine is brought into ester combination with phosphoric acid by heating with metaphosphoric acid, metaphosphates or monobasic phosphates.

Arsenic.

The organic compounds of this element are of great importance and interest. Arsenic may be brought into organic combination in a variety of ways.

1. Distillation of arsenious oxide with potassium acetate gives Cadet's fuming liquid, from which Bunsen prepared the cacodyl compounds and cacodylic acid.

2. Tetramethylarsonium iodide and some trimethylarsine are obtained by the action of methyl iodide on sodium arsenide (Cahours and Riche).

3. Arsenious halides react with zinc-alkyls (Hofmann).

4. Arsenious halides react with mercury aryls (Michaelis).

5. Sodium removes halogen from a mixture of arsenious chloride and aryl halide (Michaelis).

6. Aromatic compounds sometimes react with arsenious chloride, hydrogen chloride being eliminated (Michaelis); a corresponding reaction takes place with the sodium derivatives of some ketones (Morgan and Micklethwaite).

7. Arsines can be obtained by the action of Grignard's reagents on arsenious chloride (Pfeiffer).

8. Methyl iodide and sodium arsenite give sodium methyl arsinate (v. Meyer).

9. By alternate reduction and methylation this reaction may be made to furnish cacodyl compounds and trimethylarsine oxide (Auger).

10. Arsenic acid reacts with amines and phenols, giving amino- and hydroxy-aryl arsinic acids (Béchamp; Ehrlich and Bertheim). These may be reduced to arsenoso- and arseno-compounds.

11. Diazonium salts react with arsenites to give aryl-arsinic acids (Bart.).

12. Arsenious chloride adds on at the triple linkage of acetylenic hydrocarbons (Bayer and Co.).

Cacodylic acid—$(CH_3)_2AsO\cdot OH$—is usually administered in the form of the sodium, magnesium, or iron salt.

Arrhenal—$CH_3\cdot AsO(ONa)_2 + 5H_2O$—is the disodium salt of methylarsinic acid.

Of late years chief interest has centred round the aromatic compounds of arsenic on account of their pronounced action in protozoal diseases.

Atoxyl, sodium aminophenylarsinate, was the first of these substances to be introduced therapeutically. Béchamp (*Compt. rend.* 1863, 56. i. 1172) heated aniline arsenate to 190°-200°, obtaining a substance which he took for an anilide of arsenic acid. Using our present atomic weights the reaction would be represented by

$$C_6H_5NH_2, H_3AsO_4 = H_2O + C_6H_5NH\cdot AsO(OH)_2.$$

It was assumed that the substance known as "Atoxyl" was such an anilide. In 1907 it was chemically examined, found to contain sodium (Fourneau, *J. Pharm. Chim.* 1907, vi. 25. 332), and, thanks to Ehrlich and Bertheim (*Ber.* 1907, 40. 3292), shown not to be an anilide but to contain a free amino-group. Atoxyl is, in fact, the monosodium salt of *p*-aminophenylarsinic acid. This was clear since the compound could be diazotised without removing the arsenic, whilst by replacing the arsinic group by iodine, *p*-iodoaniline was formed. Several salts and derivatives were introduced as antisyphilitics.

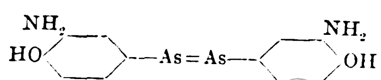
Argatoxyl.—Silver salt.

Asiphyl.—Mercuric salt.

Arsacetin.—$CH_3CONHC_6H_4AsO(OH)_2$.

Hectine.—$C_6H_5SO_2NHC_6H_4AsO(OH)_2$.

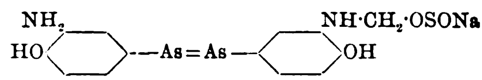
Salvarsan.—The most important synthesis amongst the aromatic arsenic compounds is that of salvarsan—



Hydroxyphenylarsinic acid is obtained either by the diazotisation of atoxyl or by the direct action of arsenic acid or phenol. The compound is then nitrated to *m*-nitro-*p*-hydroxyphenylarsinic acid, and the nitro- and arsinic-groups reduced in turn to amino- and arseno-groups.

Sodium hyposulphite is employed as reducing agent, and the sulphur found in commercial salvarsan appears to be in actual combination, possibly as a sulphamo-group (Fargher and Pyman, *Trans. Chem. Soc.*, 1920, 117, 370).

Neosalvarsan has the formula—



Its ready solubility in water is an advantage over salvarsan.

Ehrlich and Karrer (*Ber.* 1915, 48. 1634) have made additive compounds of salvarsan with several metallic salts. The compound with $1\,CuCl_2$ is stated to be very active against trypanosomes, and the curative dose is only 15 per cent. of the lethal dose.

The constitution of silver salvarsan and allied substances has been dealt with recently by Binz, Bauer and Hallstein. (*Ber.*, 1920, 53, [B], 416.)

Danysz (British Pat. 104496, 104497) finds that many of the compounds of salvarsan with metals are unstable and easily decomposed by alkalies. By making antimonyl derivatives compounds may be obtained containing silver, mercury and other metals; these are said to be more soluble, more active, less toxic, and to be stable in alkaline solution.

In this connection it may be mentioned that von Heyden (D.R.P. 296940) obtains organic compounds containing antimony by diazotising amino-derivatives of arsenic compounds and allowing the diazonium salts to react with antimonites.

Antimony.

But few compounds containing antimony directly attached to carbon have found medicinal application.

Sulphoform is a trade name for triphenylstibine sulphide $(C_6H_5)_3Sb : S$; it has been used in dermatological practice.

Bismuth.

The compounds of this metal have a very favourable action on wounds, and some of them may be used as iodoform substitutes. The internal uses of bismuth are also well known.

Many artificial preparations have been introduced into medicine in which the bismuth is present as positive radical of a salt, not in direct combination with carbon.

Airol, Airoform, Airogen— $C_6H_2(OH)_3COOBiI(OH)$.

Bismal.—Methylene-digallate.

Dermatol.—Basic gallate.

Eudoxin.—Basic salt of tetraiodophenolphthalein.

Gastrosan.—Basic salicylate.

Hetoform.—Basic cinnamate.

Iodylin.—Iodosalicylate.

Neoform.—Basic triiodophenolate.

Orphol.—Basic betanaphtholate.

Phenolate.—Basic.

Xeroform.—Derivative of tribromophenol.

Sulphur.

The presence of this element, together with the unsaturated nature of the compounds, seems to be responsible for the properties of the various ichthyol preparations made from the bituminous shales of the Tyrol.

Iron.

This element does not form proper organo-metallic derivatives. The various preparations containing iron and protein cannot strictly be looked on as synthetic compounds.

I have great pleasure in acknowledging the kind help afforded by the following firms, who have lent specimens in illustration of these lectures:—

PAPER-MAKING MATERIALS IN THE PHILIPPINES.

The Philippine Islands produce an abundance of fibres and other raw materials for the manufacture of paper pulp on a commercial scale, but at present none of these is being utilised for this purpose. So far as is known, no paper has ever been made in the Philippines except for experimental purposes. The country also contains plenty of the raw materials required for the manufacture of the chemicals used in paper pulp making, but none of these chemicals is now being produced locally.

More than a decade ago, Mr. G. F. Richmond, for several years attached to the chemical laboratory of the Philippine Bureau of Science, made a very careful survey of the materials available in the Philippines for the manufacture of paper pulp, but, according to a report by the U.S. correspondent at Manila, no practical use has yet been made in the islands of these valuable data.

The experiments made by the Bureau of Science were undertaken with the object of determining the commercial availability, for paper-making, of the fibres from members of the plantain family, such as abaca (manila hemp), banana, and plantain; of maguey (*Agave cantula*); of certain palms; of bamboo; of grasses; of certain woods; and of other less important plants.

Bamboo.—Of all the materials for the manufacture of paper found in the Philippines, the bamboos are the most important, considered from every standpoint. Not only is the paper made from bamboo of excellent quality, but a constant, adequate, and accessible supply of this material could be made available for a paper or pulp factory more readily than could such a supply of any other material. Its rapidity of growth is an important item among the various qualities that render bamboo valuable as a paper-making material. Experiments were made with the two most important and widely-distributed bamboos. These are the common, thick-walled variety (*Bambusa blumeana*), and the thin-walled, dwarf bamboo, also known as caña bojo, of the genus *Schizostachyum*.

The thick-walled variety is that commonly employed for building purposes throughout the islands. It is planted as a crop along the river bottoms of the Pampangan plain, on Luzon, and in other sections of the Philippines as well. Propagated from cuttings, the plants are set out in rows from sixty to ninety centimetres apart. Marketable culms are produced in from one to two years.

The caña bojo, or dwarf bamboo, is that employed throughout the Philippines for the manufacture of woven products used for furnishing the interiors of nipa houses and for other purposes, such as the *sauale*, *quisame*, and *amatong*. The caña bojo is found almost entirely within the forested regions of the country and is a veritable forest pest. It is never cultivated, but is cut without restraint in the forest regions to prevent its deleterious effect on forest growth.

In the Province of Bataan there are two contiguous areas of caña bojo, one of them containing 1,200 hectares (hectare = 2·47 acres), 800 hectares of which are covered with a dense stand of caña bojo. The other area includes about 650 hectares, of which over 40 per cent. is covered with this variety of bamboo. Small areas of caña bojo are found in the same province along the Bamban, Buasao, Pinulot and Bacan rivers, in the basin of the Colo River, and in the basin of the Mababo or Balsic River. Some of these areas contain a higher percentage of timber trees than do others, and are, consequently, less thickly studded with bamboo. In an average stand of this variety of bamboo there are about 9,000 culms to the hectare. An ordinary green cane weighs 7·2 kilos, and an air-dried cane, without the nodes, weighs 3·75 kilos. A hectare would, therefore, produce about 33·75 metric tons of dried material. Mr. Richmond calculated from his experiments that two metric tons of air-dried material would produce about one short ton of pulp. The yield of pulp would consequently be approximately seventeen tons to the hectare, or nearly eight tons to the acre.

The experiments made by Mr. Richmond developed the following important facts in respect to bamboo as a paper-making material:—

1. The dwarf bamboo (caña bojo) is better than the variety used for building purposes, in that it yields more unbleached pulp and requires less of the bleaching agent to give the best results. The structural bamboo requires from 20 to 25 per cent. of bleach to give but poor results, but a satisfactory white is obtained from dwarf bamboo with from 10 to 20 per cent. of bleach. This compares well with the results obtained from straws of various kinds.

2. A well-digested pulp is obtained from bamboo by the use of from 10 to 20 per cent. of caustic soda, calculated on the gross weight of the stems.

3. The time required for digestion, the pressure and the temperature employed are materially less than those required in making pulp from soft woods by the same process. In fact, in these particulars, bamboo compares favourably with straw and similar materials.

4. Both the sulphite and soda processes may be employed in working up caña bojo. By the former process, fully 50 per cent. of unbleached pulp may be obtained, and that, with the use of much less sulphur than is necessary for the making of wood pulp. By the latter process 43 to 45 per cent. of air-dry, unbleached soda-pulp is obtained. The use of caustic soda is recommended for bamboo because of certain difficulties to be overcome in the use of the sulphite process. The results described were obtained by the use of caustic soda under the following conditions: (*a*) Upright cylindrical stationary digesters; (*b*) direct live-steam heat; (*c*) 15 to 20 per cent. of 76 per cent. caustic soda, calculated on the air-dry weight of the raw material; (*d*) a duration of cooking of from four to six hours; (*e*) a maximum temperature 160° C. (320° F.) corresponding to a steam pressure of 45 kilos.

5. Pulp obtained by the sulphite process is not light enough in colour to be mixed with

mechanical wood pulp in the manufacture of news-print paper. It is entirely suited in point of colour for use as a wrapping paper. But it is too valuable, by reason of its fibre, to be used for wrapping paper or for the making of newspaper stock. The strength of bamboo fibre makes it specially adapted to the manufacture of book paper and certain grades of writing and lithographic papers. For these purposes it may be used alone or mixed with rag or sulphite wood pulp.

6. If the bamboo pulp is to be used in the making of book and lithographic papers, the soda process should be employed in its manufacture, because bulk, softness and opacity are the chief features of soda pulp. This pulp bleaches to an excellent white with from 12 to 15 per cent. of bleaching powder. The resulting sheet is more bulky than that from wood pulp and possesses a strong fibre 2·5 to 3 millimetres in length—longer and narrower than spruce fibres—and a good felting capacity.

Abaca or Manila Hemp.—The Philippine Archipelago is the home of abaca (manila hemp), the source of all materials from which the genuine Manila hemp paper is made. The plant (*Musa textilis*) is a species of wild banana, of which there are several found in the Philippines. The fibre from this plant is the world's premier cordage material and comprises the chief article of export of the Philippine Islands.

Abaca waste, available for paper-making, is of two kinds, namely, that made up of old worn-out rope, gunny sacks, waste thread, and binder twine made from the fibre; and the true abaca waste, *i.e.*, the fibre that is missed in the stripping of abaca or extracting the fibre from the stalk of the plant. There is very little of the former to be had in the Islands. When abaca waste is mentioned in the Philippines, the term signifies that portion of the fibre that is missed or thrown aside with the stalk pulp at the time of, and in the process of stripping the fibre or extracting it from the plant, either in the hills or on the plantations where it is grown.

Abaca, the fibre extracted from the plant of the same name, is taken from the petioles or sheath-like leaf stalks, which, wrapped one about another, form the stem or trunk of the plant. The stripping process consists of separating the fibre from the cellular matter of the petiole.

From this process two kinds of waste material are obtained, both of which are of value in paper-making. One of these is called fibrous waste, and the other semi-fibrous waste. The former is made up of the broken, tangled, or lost but clean fibres mixed with strips or bands of fibre aggregates from which the cellular and incrusting matter has not been entirely removed. The fibre contained in this waste has all the qualities of the fibre that is recovered by the stripper and subsequently employed in the manufacture of cordage. It is therefore identical with the fibre contained in rope waste, well known among manufacturers of paper. There is this difference, however; this fibre is fresh and has not suffered the deterioration of age.

The semi-fibrous waste resulting from the process of stripping abaca is due chiefly to the method by which the stalk of the plant is made ready for the stripping process. The plant is prepared for hand stripping by cutting off a portion of each end of the stalk to facilitate the removal of the petioles. Several of the outer of these are usually discarded on account of being bruised and discoloured. The fibre which is recovered as the abaca of commerce is contained chiefly in the outer surface of the petiole. The inner surface of the petiole and the portion between the two surfaces are made up, for the most part, of cellular matter, although they also contain much fibre of a lower tensile strength than that contained in the outer surface.

After the petiole has been removed from the plant stalk, preparatory to stripping by the hand process, ribbon-like strips are peeled from the entire length of its outer surface. Only these thin, fibrous ribbons are submitted to the hand-stripping process. All the remainder of the petiole is discarded. As already pointed out, this discarded portion, while containing chiefly watery, cellular matter, also has much fibre that is valuable, though never recovered by the hand process of stripping. This cellular portion of the petiole, the discarded outer petioles and the cut ends of the stripped petioles make up the semi-fibrous waste of abaca.

The habitat of abaca is in southern Luzon: the Provinces of La Laguna, Cavite, Batangas, Albay, Ambos Camarines, and Sorsogon; Samar and Leyte and southern Mindanao, chiefly. A mill situated anywhere in the islands would require a more or less considerable haul for most of its supply of abaca waste. It would also have to solve the problem of collecting the waste in the various regions where it is produced. Undoubtedly this would be an easy matter. Once abaca growers knew that there was a market for the waste at a price to leave a reasonable margin of profit over the cost of baling and collecting, the waste would be taken care of as systematically as is now the case with cordage fibre. In fact, a considerable amount of this material has been collected and exported from the Philippines at different times.

The semi-fibrous abaca waste, owing to the length of time, the pressure and the strength of caustic soda required to remove the cellulose matter, cannot be used profitably in the manufacture of the better grades of paper. But this material might readily be manufactured into wrapping paper of the sort in which strength and cheapness are of more importance than colour, by the process employed in working up

jute—that is, by the use of lime, cooking under pressure, and partial bleaching.

Grasses.—Grasses of several varieties have long been in use for the manufacture of paper stock. Perhaps the most widely known of these is the esparto grass (*Stipa tenacissima*), for many years an article of commerce in the Mediterranean countries. This grass has been employed in some of the mills of Europe for many years. In India, the Bhabar grass (*Ischaemum angustifolium*), which yields a paper but little inferior to that of esparto, is very generally in use. The Munj grass (*Saccharum sara*) and several other grasses of the same species are constantly used. The paper industry of India is founded principally on these grasses and has become very extensive.

Mr. Richmond experimented with two Philippine grasses, cogon (*Imperata exaltata Brong*), and Talahib (*Saccharum spontaneum*), and found each to be an important source of paper stock. Cogon grass grows from two to four feet in height, and is found in even stands on open lands, foot hills, and low mountains in almost every part of the Philippines. It is broad-leaved, gregarious, and thrives with but little moisture on almost any sort of land. In many sections of the Islands, where nipa is not to be had, the natives rely on cogon grass roofing and siding for their houses.

Cogon grass is found in abundance in the central plain of Luzon on most of the open land. In the Province of Tarlac, between Capas and Concepcion, there is a good stand of cogon grass covering a level area of abandoned rice and sugar land. The grass on this area is usually of good stand and quality. Throughout Tarlac Province and, to a less extent, in the adjoining provinces, there are large areas of open land covered with cogon grass of good quality. Cogon grass is also abundant in the Visayan Islands.

Cogon grass is not jointed. This quality is regarded as of great advantage in the matter of making paper pulp. Its yield is from 5 to 10 per cent. more than that of cereal straws, and it is more easily pulped with a smaller proportion of caustic soda. It has the further advantage over cereal straws that it can be harvested just before it is ripe, a period when it gives the best results. Cogon is easily prepared for digestion, and requires no preliminary cutting down after being dried, hand-picked, or machine cleaned.

Talahib (*Saccharum spontaneum*) is a coarse jointed grass growing from six to ten feet tall. It is gregarious, and springs in tufts from stout underground root stalks. Talahib is often confounded with cogon grass. It is very different from the latter, however, in both its appearance and habits of growth. Talahib thrives best in low, moist land and flourishes in river valleys and areas subject to annual floods.

This grass generally occurs with or near cogon grass, growing vigorously in the wet places where cogon does not do so well, and being of a poor variety on the uplands where cogon thrives well. It is difficult to get rid of. Cutting and burning has but little effect on it other than to increase its yield and quality. Talahib is related to the *Saccharum sara* (the Munj grass of India) and *Saccharum officinarum* (the sugar cane of tropical countries).

An experiment carried out by Mr. Richmond with a small quantity of talahib, fully matured with entire stems and leaves, gave as result a percentage of 53·9 of cellulose.

Bananas and Plantains.—Plantains (*Musa paradisiaca*) and bananas (*Musa sapientum*) contain much fibre that might be utilised in the manufacture of paper stock. These plants abound almost everywhere in the Philippines. Probably close to 100,000 acres are planted to them. The fibre from them has not the tensile strength of abaca, but this is considered by Mr. Richmond an advantage when the fibre is to be employed in the manufacture of paper pulp. Nearly 20,000,000 bunches of fruit are gathered yearly in the Islands from these plants, and there are, therefore, a like number of full-grown stalks which annually go to waste, since practically no use is now made of them. The figures do not include the wild non-edible plantains, which are common throughout the Philippines and which might be utilised in the making of paper stock.

The chemical investigation of plantain fibre carried out at the Bureau of Science showed a percentage of 68·21 of cellulose. There appears to be no good reason why a plantation of bananas might not yield a profitable revenue from its fruit, and at the same time supply a pulp mill with the stalks discarded when the fruit is harvested. At the present time no bananas are exported from the Philippines, nor is the domestic market as well supplied as it should be, considering how valuable the fruit is as an article of diet.

Maguey Waste.—Maguey (*Agave cantula*) and sisal are being extensively planted in several sections of the Philippines. These plants yield a fibre that is well known to the cordage world. This fibre is extracted by retting at present, but a movement is on foot to revolutionise the methods of recovering it by the introduction of machines. When maguey and sisal fibre is extracted by machinery there is a considerable quantity of waste that is comparable to abaca waste. The maguey, owing to the nature of the leaf of the plant, is considerably more bulky than abaca waste.

Other Materials.—Bowstring hemp (*Sanseveria zeylanica*) is found in many parts of the Archipelago. It is not, however, of commercial importance. It has possibilities and might be cultivated for its fibre, which is not unlike that of maguey.

Coconut coir (husk fibre) might be produced in abundance in all the coconut regions. At the present time this by-product of the coconut industry is almost entirely neglected. It might be utilised very profitably in the manufacture of paper.

The leafstalks of the nipa palm contain valuable paper substance. At present little or no use is made of these, though a vast amount of the nipa leaf is used in almost every section of the islands for thatch and siding for houses.

The buri palm is widely used in the manufacture of hats and other handicraft products, and yields an immense amount of waste in the process of extracting the material utilised for these purposes. No small part of this waste might be employed in the making of paper stock.

The milling waste of certain soft Philippine woods is known to be valuable as a source of paper stock. Mr. Richmond made successful experiments with lauan, kupang, and similar varieties.

It is not conceivable that any of the minor sources of paper pulp mentioned above would alone yield enough material to keep a mill in operation, but, nevertheless, they are not altogether negligible at a time when the world appears to be facing a shortage of such substances.

Raw Materials for Paper-Making Chemicals.—It is the opinion of the Director of the Bureau of Science that caustic soda, sodium sulphite and the bleaching powder required in the manufacture of paper could be manufactured in the Philippines if there were a demand for them. At present all such chemicals are imported.

GENERAL NOTES.

BRITISH SHIP-REPAIRING INDUSTRY. — The Government were asked in the House of Commons on August 16th whether much of our ship-repairing work is going to Antwerp and Rotterdam. The Parliamentary Secretary to the Ministry of Shipping admitted that there is a considerable slackening in the repairing industry in this country, causing unemployment, and that there is also a tendency for some of the work to go to Continental ports, "where, it is alleged, costs are lower."

THE INSTITUTE OF METALS.—By invitation of the Mayor and Corporation of Barrow-in-Furness the autumn meeting of the Institute of Metals will be held at that place on September 15th and 16th. Amongst the papers to be submitted are the following: "The Allotropy of Zinc," by Miss Kathleen E. Bingham, B.Sc.; "Crystal Growth and Recrystallization in Metals," by Professor H. C. H. Carpenter, F.R.S., and Miss Constance F. Elam; "The Constitution of the Alloys of Aluminium and Magnesium," by D. Hanson, M.Sc., and Miss Marie L. V. Gayler, B.Sc., and "Notes on Brass Foundry Practice at Messrs. Vickers, Limited, Barrow-in-Furness," by H. B. Weeks, F.I.C. The programme includes works visits to Messrs. Vickers, the Barrow Hematite Steel Works, the Furness Railway, the Barrow Paper Mills, the Hodbarrow Mines, the Millom and Askam Hematite Iron Works, and the North Lonsdale Iron Works.

PEARL FISHERY OF ECUADOR.—The production of the pearl fisheries off the coast of Manabi—between the ports of Manta and Machalilla—for the fishing season from March to October, 1919, was valued at 25,052 sucres (about £2,500). The United States Consul-General in Ecuador states that during the month of October, 6,508 pounds of pearl shell were shipped out of Manta. Of this amount France received 2,231 pounds, Italy 1,903 pounds, Panama 1,583 pounds, and the United States 791 pounds. France also received 12 pounds of fine pearls.

SCARCITY OF MANGANESE SUPPLIES.—The serious scarcity of the supplies in this country of ferro-manganese ore, an article so needful in the manufacture of steel, has formed the subject of questions in the House of Commons. *Inter alia*, complaint was made of large quantities in India passing into alien, and ultimately into late enemy hands. The President of the Board of Trade stated that action had been taken to improve transport conditions in India, which had been restricting exports, and the imports into the United Kingdom had shown a steady improvement in the last three months. Another point raised was the shortage of railway trucks for conveying the ore to Indian sea-ports. The Secretary of State for India, Mr. Montagu, said he had been in correspondence with the Government of India on this subject for a considerable time, and had asked them to take all possible steps for facilitating transport. It appeared that on July 10th there were stocks of 74,374 tons of the ore at Calcutta, and on July 30th of 9,000 tons at Bombay. Provision had been made for the carriage of 500 tons daily to Bombay. Mr. Montagu said he is aware that both the United States and Japanese steel trades have agencies in India for buying ferro-manganese ore.

PAPER FROM BRITISH COLUMBIA.—British Columbia is now producing 645 tons of paper daily, or about 7,000,000 tons annually—eleven years ago the province was not producing any at all. The progress made in the last eleven years is being maintained, so that during the next few years a considerable increase in the pulp and paper industry of the province is anticipated. British Columbia, according to the *Empire Mail*, produces 14 per cent. of the pulp and paper manufactured in Canada — the second largest paper-producing country in the world — at the present time, being the third largest producing province. Quebec produces 24,000,000 tons and Ontario 21,000,000 tons annually.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE ARCHITECTURE AND DECORATION OF ROBERT ADAM AND SIR JOHN SOANE, R.A. (1758–1837).

By ARTHUR T. BOLTON, F.S.A., F.R.I.B.A.,

Curator of Sir John Soane's Museum.

Lecture I.—Delivered May 3rd, 1920.

The opening date of the period which has been taken as the subject of these Cantor Lectures is that of Robert Adam's return from his memorable grand tour, which extended from the summer of 1754 to January, 1758.

The closing date is that of the death (January 20th, 1837) of Sir John Soane, who was born in 1753 and came to London in 1768, the year of the launching of the famous Adelphi enterprise.

Any such selection of dates is, of course, purely arbitrary as one period blends into another, the seed of any change of style has long been germinating, and while all can mark the new growth when it has shot up, few can detect the transitional stages of its development. From the time of the introduction of pure Italian architecture into England by Inigo Jones, in the reigns of James and Charles I., a tolerably regular line of development had been pursued, in spite of the gap caused by the Civil War.

The work of that great architect was the object of the enthusiastic regard of the school of Burlington and Kent. James Gibbs, the immediate leader before Robert Adam, had died in 1754. He was very fairly characterised by Walpole, who said that "Gibbs' merit was fidelity to rule, his defect a want of grace."

The work, therefore, of the period of the two first Georges had been a solid and consistent whole, which it now became the mission of Robert Adam, as a revolutionary artist, to break up and transform. The opening of a new reign in 1760 was of itself a favouring circumstance, and in ten years from that date imitation of Adam work had become general. The commencement of the long ministry of Lord North (1770–1782) marked the close of the troubled period of the transition from the Early to the Late Georgian, and the year 1775, that of the mid-point of Robert Adam's career in London (1758–1792), coincides with the high-water mark of that epoch of prosperity and magnificence. Everybody knows how the American and other wars clouded over the fair prospects. In 1780 occurred the Gordon Riots, in 1782 the Ministry collapsed, and a real recovery was only commencing when the death of Robert Adam took place (March, 1792), almost simultaneously with that of Sir Joshua Reynolds.

In 1793 the Revolutionary Wars began which were almost continuous up to 1815. By the time that peace was re-established after Waterloo a new generation had sprung up, to whom Robert Adam was merely a name, almost a legend, and one grown so distorted that in the current view the Adams had been little better than speculative builders.

Adam work was freely destroyed for the next half century during the ascendancy of the Greek and Gothic Revivals, and it has been the work of this generation to re-establish its fame.

There is a closer link than is generally supposed between the work of Soane and Adam. By reason of his marked personality and long life, Sir John Soane came to be respected and even venerated as the veteran heir of the age before the great wars of the Revolution.

As gold medallist of the Royal Academy (1776) he had been introduced to George III. by Sir William Chambers himself. He was the pupil of George Dance, R.A., and had been an assistant in the office of Henry Holland, jun., and could claim to have been the friend of Robert Adam, James Stuart, and James Wyatt,

who had been the leaders of that remarkable epoch.

Soane as an artist, moreover, was an outcome of Robert Adam's revolutionary mission, belonging more to the Adam and Dance group than to the more orthodox school of Chambers, Taylor, and Paine.

The fundamental idea of Robert Adam that lay at the root of his revolution was the thesis "that the domestic architecture of the Greeks and Romans was entirely distinct from that of their temples." This proposition, which may, perhaps, be regarded as merely a commonplace to-day, called in question the validity of the system of the orders which had been the subject of so much study since men had first turned to the remains of Roman antiquity as a new basis for building, in the earliest days of the Renaissance.

Palladio had systematised the use of the orders, and the universal admiration for his building achievements at Vicenza and Venice had carried his style throughout Europe. His "Architettura" (1570) had been Inigo Jones's handbook in Italy, and the Anglo-Palladian School was fortified by more than a century of successful practice in England.

Robert Adam's earliest work, after his return in 1758 from Italy, is leavened by this tradition, and there has always been a body of opposition to his revolutionary theories and their application in architecture.

Soane accepted Adam's basis, but modified it by the adoption of those Greek ideas and details against which Sir William Chambers had thundered in vain. The Bank of England, to which Soane had been appointed architect in 1788, was the field in which from 1794 onwards this later revolution of Soane's was manifested. The opposition was intense; the feelings of the remnant of the old school were outraged by the young architect's substitution of such unorthodox work, in place of the sound tradition of the school of St. Martin's-in-the-Fields.

After the great war the older school was practically extinct. The Greek and Gothic revivals were in possession of the field, until, in the last years of Soane's life, a new chapter was commenced by the introduction of the Florentine and Roman, Astylar manner, introduced by Sir Charles Barry, R.A. Sir John Soane, R.A., who had started under the influence of Robert Adam, showed in his last work, the new State Paper Office (1829–33), an evident appreciation of this fresh departure.

As all are aware, Robert Adam was the second of four sons of William Adam, sen., an architect of large practice in Scotland up to the time of his death in 1748. John, the eldest of these sons, passed his life in Edinburgh and on his estate at Blair Adam. Robert, the second son, born in 1728, was educated from the age of fifteen at Edinburgh University. James, the third son, born 1730 (?) was also entered there, but under the Greek in place of the Latin professor. Of William, the youngest of the group, very little is known; he seems to have been the business agent of the London practice of Robert and James. As the survivor of the group, living until 1822, he deserves remembrance because it is through his care that the priceless collection of Adam drawings in the Soane Museum has survived.

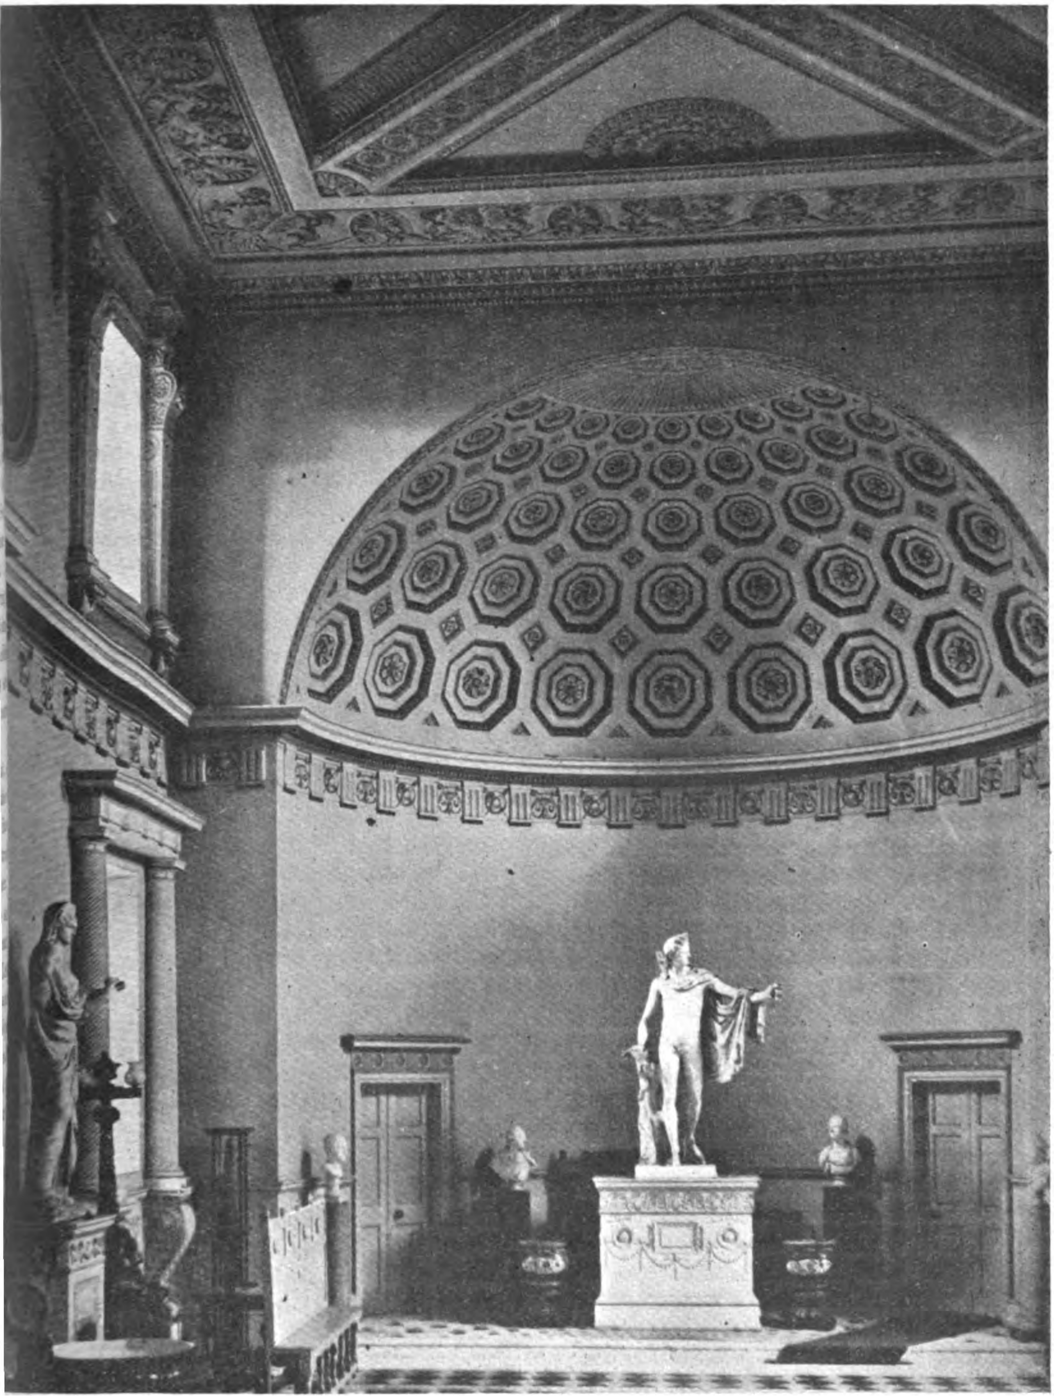
As was stated at the outset Robert returned from his memorable grand tour of nearly four years' duration in January, 1758, and the remainder of his life was passed in London, varied by repeated journeys to Scotland and over all England, in connection with his extensive practice as an architect.

James may be regarded as having been chief of the staff to Robert, while John's position seems to have been that of the eldest brother, to whom a certain deference was shown, as by the inclusion of his name in the contracts, etc., of the Adam Brothers.

There is nothing to show that, apart from the genius of Robert, any one of the other three sons of William Adam, sen., would have achieved anything above the sound and traditional, if heavy and dull, work of their father.

As is well known James made an extended tour from 1760 to 1763 in the early days of Robert's commencing practice in London. He collected pictures, antiques, books and drawings abroad, and directed various studies by draughtsmen and others, as though intending some important work. The architectural results of his tour were, however, unimportant in comparison with that of Robert's earlier tour.

At the same time too much importance has been attached to Robert Adam's highly successful book of 1764 on Diocletian's Palace at Spalato, which he had studied on the spot in 1757. The value of this study was that it enlarged his idea of ancient domestic architecture, and confirmed the view that he had already taken as to the essential difference between the temple architecture of the Greeks and Romans and that of their private houses. The allegation that the Adam style derives from this late Roman work on the coast of the Adriatic is a pure myth, as



SYON HOUSE. THE HALL.

anyone who looks at the book with attention will soon discover. Robert Adam's studies abroad were pursued in a very catholic spirit, and the work of the Early Renaissance, of the Romanesque, and even the Mediæval ages, was not without its effect upon his mind.

As the son of an architect and one who had already certainly taken part in actual work, Robert set out on his grand tour with an exceptional equipment, and on his return he had the ability, knowledge, and fortune, that enabled him to undertake at the outset of his career in London, work of very considerable importance. He seems, therefore, to have escaped the long and trying period of unemployment that is the usual fate of the beginner in architecture.

Before dealing in some detail with a selection from the innumerable works of the Brothers Adam, from 1758 to the close of the century, it will be as well to consider the character and direction of the movement initiated by Robert, because it will be evident that the Adam revolution in style was not merely one of internal architecture and decoration.

No such separation is, in fact, possible, and it was soon evident that his attack on the validity of the order system in use internally could not fail to lessen its importance externally as well. Broadly speaking, the mission of Adam was a recall to the principle that in any treatment of the surface of a building, whether external or internal, the value of the relative planes may be a primary consideration. As applied to street architecture in particular, this is a principle of the greatest value, and it is not limited to any one phase of architectural style. The Adelphi, in its pristine condition, showed a masterly consideration of the problem of low relief; the rigid plainness of the background was a necessary condition of the successful distribution of the ornament in vertical pilaster strips. There was a balance of effect, which has been upset by the subsequent application of details, uncalled for, and destructive of the original breadth of effect.

Robert Adam very soon treated the orders with the same freedom externally as he had claimed internally. He asserts that the architect possessed of any degree of mastery can, and should, vary the received proportions and features of the orders. He thus freed himself of the hampering effect of deep entablatures, composed of the full architrave, frieze, and cornice, as strictly regulated by the width and height of the pilaster or column.

By decorating a plain faced architrave he dispensed with the frieze, and regulated the depth of his cornice by a consideration of its relative value to the tall and wide spaced column, or pilaster, which lent itself to his conception of elegance and decorative effect for domestic buildings. In this way he evolved the façade of an Adam character, which has become a recognised feature of our London streets. He accepted gladly the London stock brick and, whether in stone or stucco, he gave a note of contrasted effect by a sparing but always judicious use of classically derived features.

In a general consideration of the Orders he admits only three—Doric, Ionic, and Corinthian—and he sees that they are each of them representative of a different expression. Proceeding further he discriminates against the current Early Georgian use of the Corinthian with unfluted shafts, arguing with much subtlety that there are relative degrees of enrichment to be observed, and, therefore, where this could not be afforded, a simpler order must be adopted.

Contrary to the general opinion Robert Adam had a special feeling for the Doric order, which he used in his earliest days with remarkable success. The mausoleum at Bowood, as well as the Admiralty screen, may be cited as masterpieces of this application. Similar success attended his employment of the Doric in the various halls of his houses from Syon onwards; and, in his latest great work, the Edinburgh University, the great entrance is a magnificent example of the same style on a grander scale.

It is a curious fact that whereas that pillar of orthodoxy, Sir William Chambers, R.A., was mainly responsible for the Chinese mania, having at Kew Gardens practised an eclecticism of the wildest character, Robert Adam, on the other hand, recalled the taste of his age to the veritable antique.

Current domestic work, when he arrived on the scene, was split into three main currents—Italian, French, and Chinese. The Italian, through Burlington and Kent, had acquired a late Venetian character, work of the type that may be seen in the decorations of the Villa Rotunda, which are commonly regarded as of a date subsequent to Palladio's death. The Villa Maser, where Burlington acquired Palladio's drawings, was frescoed by Paolo Veronese, and the stucco work was by that architect's favourite *stuccatore*, Vittoria. Here, and in the church adjoining, the character of

the decoration is semi-barroque, such as in fact appears to have been intended by Wren himself in St. Paul's, if the well-known engraving of the interior section of the Cathedral is reliable evidence.

French work had only recently been fully exemplified in the interiors of Chesterfield House (1749), where the gilded rococo *salons* still remain, as evidence of the Earl's thesis that a house should be Italian outside and French within.

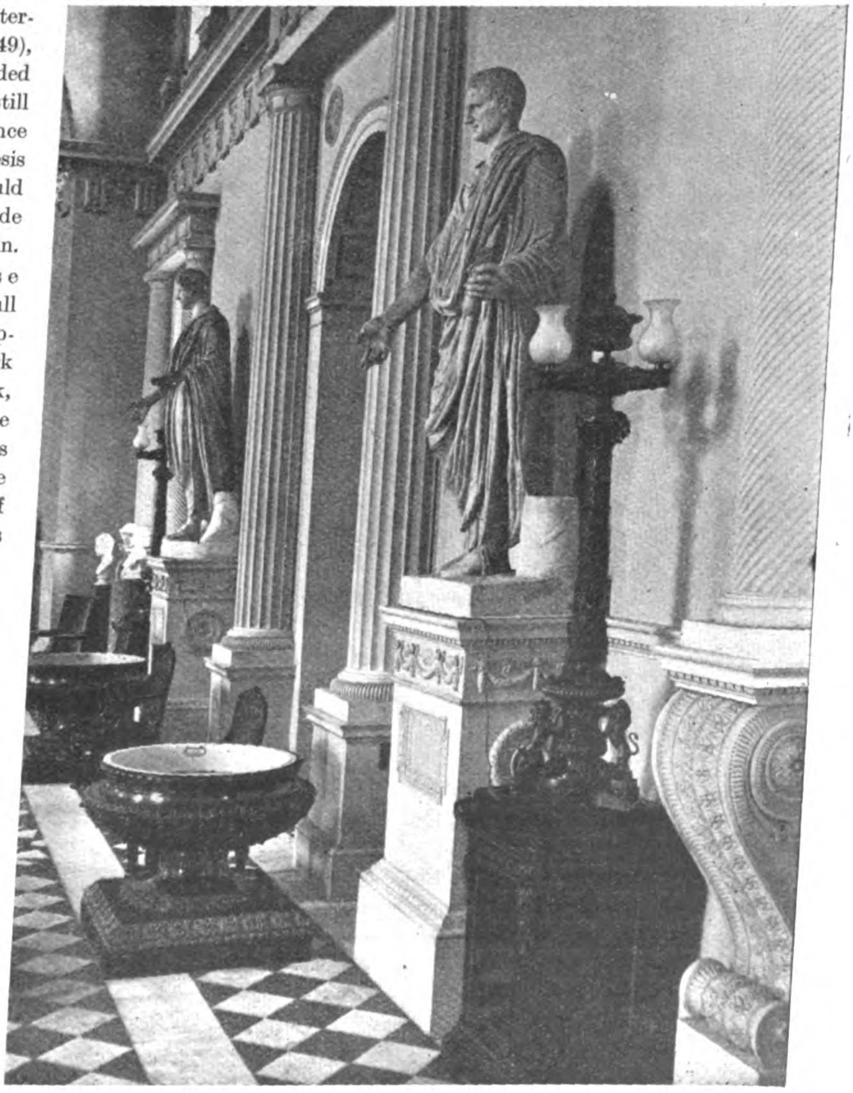
The Chinese School had the full approval of Chippendale, and work like Clandon Park, Surrey, shows the style that was fashionable in the earliest years of Robert Adam's commencing practice.

To the Italian votaries Adam proposed a return to a strict following of antiquity, as it was to be seen in the *cryptæ*, or excavated chambers of the remains of Imperial Rome, and in the newly revealed houses and remains of Pompeii and Herculaneum.

The current French work he desired to reform altogether. He set out to abolish "the absurd French compositions of this kind (interior decorations and fittings) hitherto so servilely imitated by the upholsterers of this country" (England).

Sir John Soane, in his lectures to the students of the Royal Academy, some twenty-five years after Robert Adam's death, asserts that the interlaced C scrolls, and other features of current French taste, were in actual fact for the time being driven out by Adam's reformation of the taste of his day.

The Chinese mode Adam left entirely on one side, the only concession being that, in such early work as that for the Queen of the "Blue Stockings," Mrs. Montagu, in Hill Street, 1766, he uses some Chinese pagoda-like details in the regularly disposed panels of the ceiling.



SYON HOUSE. DETAIL IN HALL.

Adam at first had considerable difficulties in bringing his executants to relinquish the well-established class of detail to which they had grown accustomed. Even in the execution of designs as late in date as 1774, as for instance the piano for the Empress Catherine, he has reason to complain that the person who

executed the work had departed from his design.

Some of the early mirror frames at Osterley can be seen to be much superior in design to their execution, and it was only where he had full control that the whole of the interior, furniture, hangings, etc., of his houses are completely true to his ideal.

The stages of Robert Adam's development are quite sufficiently marked out. Shardeloes, in Buckinghamshire, is as characteristic of the earliest stage as Home House in Portman Square is of the latest.

The actual first work, some interiors at Hatchlands, near Guildford, for Admiral Boscawen (1759–60), are clearly the student work of the young architect, on his first return from the rich storehouse of Italy. A much more serious note is struck at Syon, where the length of time over which the work extended enabled Adam to develop his ideas from the early style of the hall and dining-room to the later phase of the drawing-room and gallery.

At Kedleston the Adam scheme was hampered by the pre-existing and partly executed design of Brettingham and James Paine. Some of the work there is closely allied to Shardeloes and Syon, but a variety of difficulties prevented the full development of Robert Adam's ideas, in spite of the mass of alternative drawings, that he had made. The Great South Front, which was to be an example of his principle of "movement," remains as a fragment, a noble centre, devoid of the wings and quadrant connections, which were essential to its full effect.

This idea of "movement" is really a recognition by Robert Adam of the principle that lay behind the work of the later Roman school of Bernini and Borromini. The Italian Barroque had been a revolt against the over-systematisation of the orders, and was a claim to treat buildings as a sculptural unit that could be shaped at will, as an affair of relative masses, dependent on light and shade for an effect which might even become merely pictorial.

Unfortunately this late Italian claim for freedom was pushed to a license, which revelled in a mere inversion of recognised details, rather suggestive of a certain poverty of original invention. It has hardly been recognised that Robert Adam had ever given attention to the work of the late Roman school. The facts have been established by an analysis of his library, which proves that he had collected a choice selection of books on the subject.

Evidently Robert Adam did not agree that the architects of this school were the "blockheads" of the famous letter from Sir William Chambers to his pupil Stevens at Rome. Of this epistle Chambers characteristically gave an identical copy to young Soane, upon his setting out in 1778 upon his grand tour.

We have, therefore, without doubt, the explanation why Robert Adam was the earliest to appreciate the real merits of his predecessor, Sir John Vanburgh, to whose genius he paid a discriminating tribute, years in advance of that by Sir Joshua Reynolds, which has been so often quoted.

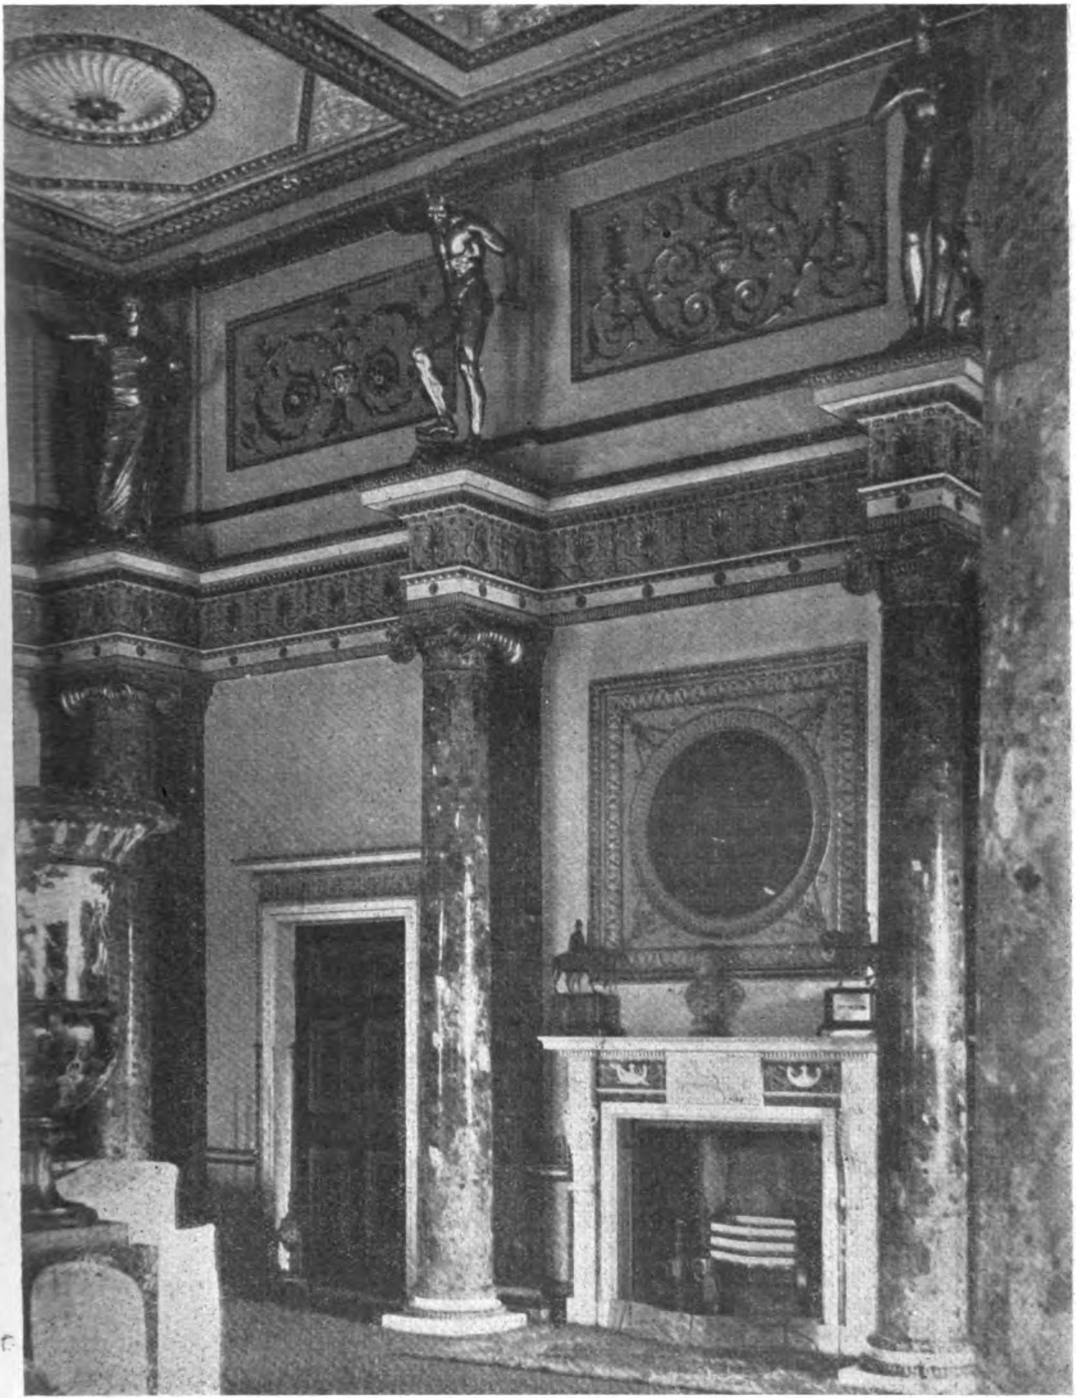
Adam had very early in his career added to houses by Vanburgh, as at Compton Verney and Kimbolton, he had certainly seen both Blenheim and Castle Howard, and thoroughly understood both the merits and defects of the earlier master.

Unfortunately, Robert Adam by the conditions and circumstances of his day never achieved that grand building, which was always in his dreams, and constituted the goal of his ambition.

At first he hoped for a royal palace for the new King, or at least for new Houses of Parliament, which would also involve new Law Courts. The Adelphi itself was really projected as a sample of a great work, worthy of comparison with the work of the Roman builders. A derelict and apparently useless sloping site was to be transformed by vast underworks raising it to the level of the Strand, where a fine terrace of houses was to demonstrate the possibilities of London improvements. Quays and warehouses below at the river level were to give a commercial backing to artistic enterprise, and this busy scene he, no doubt, saw in his mind's eye as a foreground, recalling the quays below the Imperial ruin of Spalato.

Only at the close of his life did the new University of Edinburgh afford him an opportunity of displaying his power of conceiving a great building as a whole, and of designing it in a style of broad simplicity, which surprises those who have merely considered him as an ornamentalist.

The Register House of Scotland, a much simpler problem, shows that Robert Adam could build with a simplicity and refinement that is truly Grecian. Robert Adam as an architect, in fact, demonstrates the truth that there is no real divorce between the extreme qualities of architecture. He seems by instinct to have adopted the same alternative as Sir Charles Barry in the case of the Houses of



Syon House. The Ante-Room.

Parliament, either absolute simplicity as in the elevations of the inner courtyards, or extreme elaboration as in the exterior façades of the new Palace of Westminster. The architectural quality demanded in both cases springs from the same root, a fine sense of unity in the design of the whole, by which the mass is never sacrificed to the detail.

The subordination in Robert Adam's finest work is complete, and extends to every detail, all of which are so fused in the total effect that nothing is extraneous to the design.

In his early interiors Adam was hampered by the enthusiasm of the period for the statues of antiquity. The recovery of the Greek masterpieces, through the copies of the Roman School of Antiquity, was one of the great interests of the day.

Niches were required for the Venuses, Floras, Dianas, Jupiters, and Apollos of the old Pantheon. The early Adam hall, dining room, staircase, and even the gallery, became the scene of such displays. At Syon there are three great statues on either side of the mantelpiece. Bas-reliefs, where originals were not forthcoming, are given in chiaroscuro paintings. Adam soon realised the unsuitableness of this scheme of decoration for an English interior, and, while he considered that the dining room in particular should be in stucco, so that a "smell of the victuals" might not hang about that apartment, he turned to other and more characteristic forms of decoration.

For the ceiling of these rooms an oval band, supported by wreaths of vine leaves, and enclosing crossed lines of the Bacchic thyrsus, is an early and constantly recurring motive. The band is later on interrupted and strengthened by tablets, presenting miniature bas-reliefs of classical composition.

The walls divided out into large panels above a chair rail are either filled with stucco arabesques, or left as a field for inserted portraits, or decorative landscape compositions, most often introducing ruins, antique or castellated.

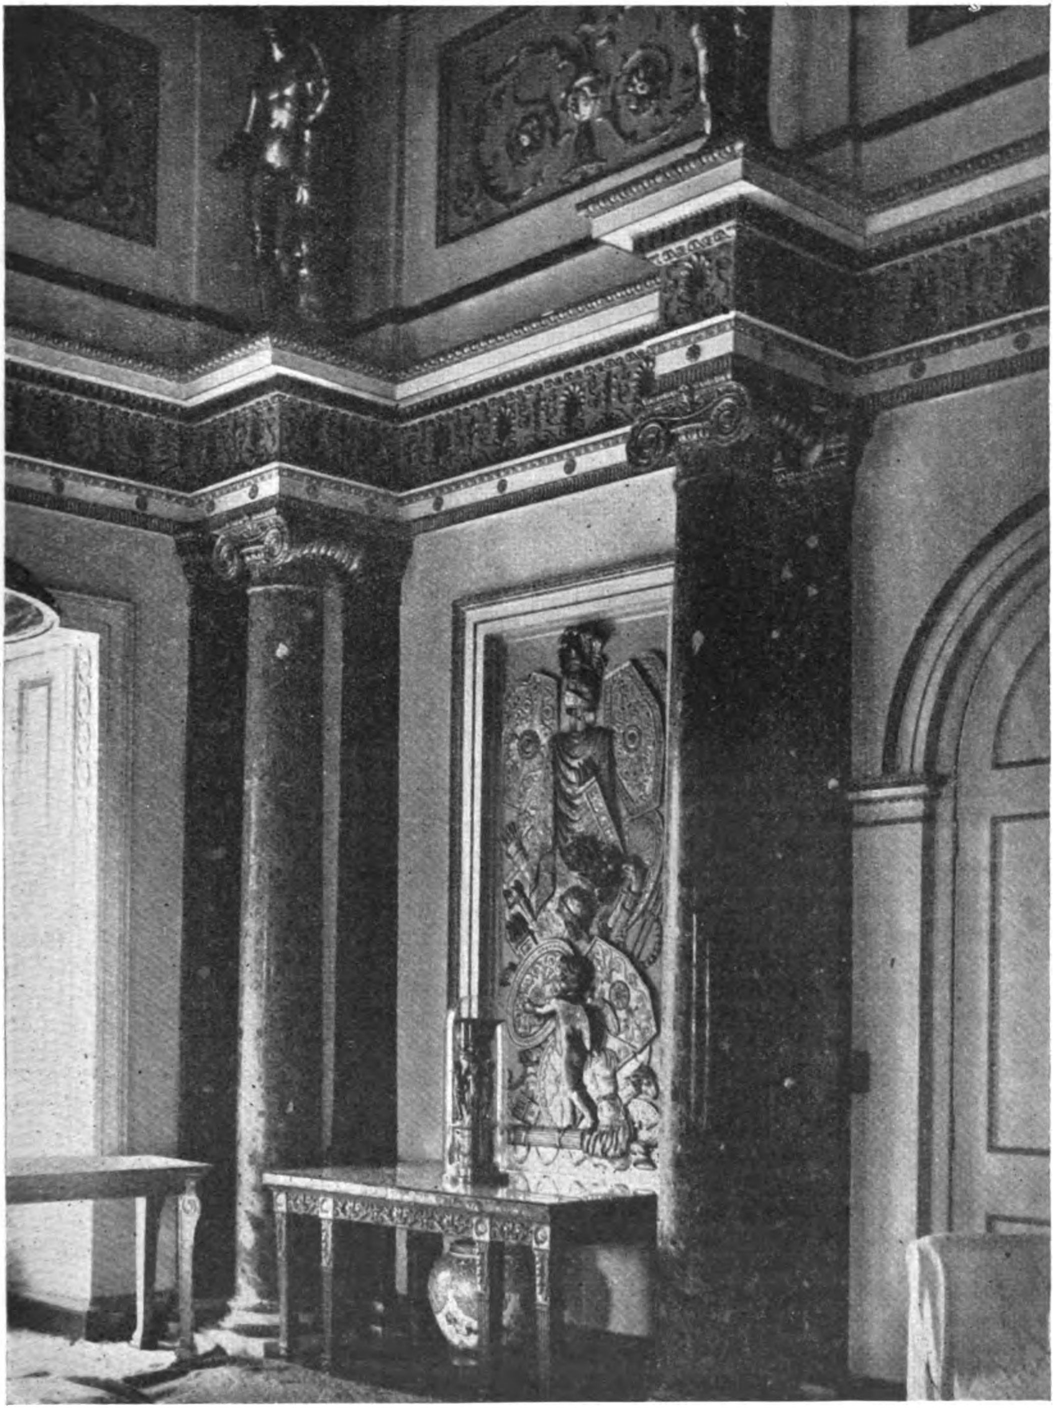
Ruins and the elements of picturesque decay had a singular fascination for an age and society which, perhaps, had a subconscious feeling that it was itself drifting towards the Niagara Falls of the Great Revolution.

Robert Adam's ruin compositions have, however, another purport in that they are essays in design, quite as much as recollections of the past impressions of his days of travel. During the slack period, following upon the American, French, and Spanish wars, he made a number of these compositions; there are some forty in the Soane Collection alone. They can be divided into two main groups—those which derive their romance from the ruins of antiquity, and others which recall his early days in the Highlands. In the latter group massive castles crown craggy heights above lakes, or rushing streams of water, crossed by long low arches of masonry. Robert was dreaming of rotundas masked as circular dungeon towers, whose buttresses should be linked together by a chain of arches, forming a ring of powerfully shadowed recesses. This revived feudalism was not to be extended to the interiors.

Culzean Castle, in Ayrshire, while castellated externally, is pure Adam classic within. His anticipatory mediævalism, where not a concession to the desires of his clients, was, in fact, due to a prepossession of his own that a broken craggy site was a reason for a design of a castle-like character. Possibly, if his travels had extended to the homeland of Greek architecture, he would have received a different impression from the relation of the temples to their mountain scenery and sites. The landscape school of gardening, originated as much by Kent as by any one person, was still in full possession of the field. Robert Adam seems never to have fully thought out the true relation of site and buildings. When he touches on that subject he seems to imply that buildings can be spread out, so as to rise up naturally out of the ground, a feat which even Blenheim cannot be said to have achieved. An Adam house in the country is apt to present the appearance of an isolated cube of masonry, seen under the most favourable circumstances at the end of a vista of trees. Terraces, forecourts, and garden walls had been proscribed by the destructive followers of Kent, and no real school of gardening existed to maintain the sound tradition derived from the gardens of Italy.

The primary object, however, of these compositions by Robert Adam was most likely that of affording ideas for the decoration of wall panels in interiors. He objected strongly to the vast pictorial compositions of the later Italian School, and their followers. Giulio Romano, in the Palazzo del Te at Mantua, had abused the Raphaelesque fresco as a means of interior decoration by an absurd attempt to obliterate the walls themselves, which presumably he had set out to decorate.

Vast canvases, in Adam's opinion, whether on the walls or ceilings, were a mistake. They trespassed on the field of architecture, and



Syon House. Detail in Ante-Room.

destroyed the scale as well as the necessary detail of the interior they purported to embellish. At Syon, in the drawing room, Adam endeavoured to restrict the painter to small flying figures, occupying the field of the octagons and circles of the great cove, as well as of the flat of the ceiling. Undoubtedly, in this instance, the figures are too small, and hereafter Adam provides medallions and lunettes, or oblongs and squares, as panels forming an essential feature of his intricate ceiling designs. In these spaces there is room for three or more figures, and the simpler classic myths are recalled by these graceful compositions.

Constantly these panels are shown in colour sketches on the detail drawings of ceilings and walls. A great variety of artists must have been engaged on works of this character, which so often now are merely ascribed to Zucchi and Angelica Kauffmann. Hamilton is particularly mentioned by Soane as preferred to the elder Smirke, R.A., who seems to have been occasionally employed by James Wyatt. The chief artist for the latter architect, however, was Biagio Rebecca.

Silk as a substitute for the costly tapestry was often employed for the drawing rooms, either in plain colours, or woven in patterns as at Syon, where the wall covering is said to be the earliest of the Spitalfields silk damasks.

Tapestry is seen in all its glory at Newby. There were four famous sets by Boucher and Neilson. The others have been at Croome, Arlington Street, and Osterley.

The drawing-rooms at Newby and Osterley are glorious pieces of colour. Every detail has been successfully combined by Adam in the general effect of the whole. He had already in the great room at Kenwood experimented in the direction of subduing the glare of a purely white ceiling ornamented in stucco by flat washes of colour. This was a very different method from the tiresome "picking-out" of parts in colour and gold, which followed in the early part of the next century. As used by Robert Adam this colour treatment is essentially a wash, intended to blend the effect of the whole, and not to isolate particular ornaments, or lines of mouldings.

Given tapestry or figured silks on the walls, woven pattern fabrics on the furniture, finely embroidered clothes, and a carpet reflecting the elaborate design of the ceiling, all with details and tones of pure, bright, and strong colour, it is elementary that a full accord would require the extension of colour to the ceiling itself.

The typical Adam interior of the period 1770–80 stands in a striking contrast to that of the antecedent age of the first two Georges, in respect of every detail that contributes to the total effect of the taste of the age. Pattern design, whether in form or colour, reached a high level, and fragments of the style have persisted, and reappear in common use, to the present day.

It is natural to inquire how far the development of Robert Adam's idea of interior treatment was modified in the course of his practice. It is possible to recognise three stages, the first in which the ornamentation, while classic in comparison with French rococo, is yet more florid and scroll-like than the work of the true Adam character. The main period is that in which architectural lines and classic types are fully observed. In the third stage a tendency to relax this severity of form may be detected, and there is an occasional use of flowers, which border on a merely naturalistic treatment.

Probably Robert Adam found it difficult to resist the pressure of common opinion, which fails to recognise the limits of the direct application of natural forms. Very few are aware of the long course of evolutionary change, which has shaped the well-established forms of classic mouldings and enrichments. The attempt to supplement these by direct transcripts from natural objects has very rarely been successful or permanent. It seems clear that Robert himself was content with the alphabet of the art of decoration, and that such attempts as those of the "Britannique order," the "Scotch capital," etc., are merely due to James Adam's vague imaginings. There was a good deal of the amateur in the composition of the third member of the Adam group.

Contemporary critics, who talked about the superior chasteness of James Wyatt's use of the antique, failed to see that Robert Adam had the better sense of the all-important distribution and spacing of ornament. His combinations of lines, and special gift of pattern-making, saved him from a variety of false effects, which are to be seen in the work of his rival Wyatt and of his colleague James Stuart.

The colour decoration of Wyatt is also inferior, because it is so often based upon an imitation of the least attractive phase of the Raphaelesque. It may be said that while Adam might have been taught by Raphael himself, Wyatt had sat at the feet of Giulio

Romano. The Cupola Room at Heaton Hall shows the hot type of colour that Wyatt favoured. Robert Adam's most original contribution to colour effects was, perhaps, the combination, which he labelled as "Etruscan Decoration."

In an age which demanded the sanction of antiquity for any fresh departure, such a label had obvious advantages. Adam puts forward an array of authors, but he is careful to explain that not much is to be gathered from them on this subject of "Etruscan Decoration." The real idea at the back of his essay was a sense of the values of earth colours, bright and dull reds, yellows, grey blues, chocolate browns and black. Horace Walpole talks of being plunged into a "chilly bathos" by the Etruscan Room at Osterley. The simplicity of the scheme startles him. He does not understand this reliance on the earliest principles of decoration, those by which a few of the simplest colours are disposed in direct contrast of hue.

So much of this interesting colour work has been obliterated by later fashion that very few examples exist in sufficient completeness. The Etruscan scheme was applied throughout walls, ceilings, hangings, carpets, and furniture. Occasionally the mantelpiece of white marble inlaid with composition is all that remains to show the original character of the colour scheme of the "Etruscan Room."

The general knowledge of antiquity, its literature, legends, and myths, as well as the common forms of their expression in ancient art, amongst the class for whom Robert Adam chiefly worked, was a valuable background for his achievements. As a source of expression the original fables were current coin. The choice of Hercules, or of Paris, the continence of Scipio, the sacrifice of Iphigenia, and the rest of the typical myths needed neither label nor explanation. To-day many of the Adam bas-reliefs and subjects of decoration have become merely a riddle to the spectator who misses the application that suggested their particular use. This power of applying universal symbols, for the expression of particular qualities, was of great assistance in the use of sculptural decoration. Abused by dulness it degenerated into an impossible conglomeration of tiresome allegorical figures, such as the great war soon after piled up under Academical auspices in the Abbey and St. Paul's.

It is worthy of note that where Robert Adam used pairs of life-sized figures in his earliest and favourite form of chimney-piece, he seems to give them no special characteristics. Their aspect is purely decorative and unhampered by any forced significance. The same seems true of the Syon Bridge design, where the three female figures have no greater characterisation than that of a group of the three Graces. This avoidance of an overcharged expression in sculpture is a lesson of the greatest value.

These lectures are not the place in which to deal with the architectural qualities of Robert Adam's planning. All that need be said here is that as house-builder he has had few equals. Numbers of his houses remain practically unaltered, and their continued occupation for more than four generations testifies in a remarkable way to their merits.

It should be pointed out, however, that in sectional treatment Robert Adam never resorts for effect to the experimentalism of George Dance and John Soane. There is no hint of eccentricity in his classic schemes, which remain true to the antique ideal of simplicity and repose. Adam taught and practised the necessity of variety, in contradistinction to the dulness of that series of oblong and square interiors, which had prevailed in the earlier Georgian times. He points out the value of the progressive effect ending in a climax, but he arrives at such a result without apparent effort, or any straining after a *coup-de-theatre*, in the manner of a Jesuit church, or late Roman Renaissance interior. This Grecian moderation is all the more remarkable because Adam was the earliest to appreciate the real merits of his predecessor, Sir John Vanburgh, and, as we have seen, he had a knowledge of the Italian barroque, and had been a close ally of Piranesi.

BRITISH ASSOCIATION.

Presidential Address.

The Cardiff meeting of the British Association opened on Tuesday, when Dr. William A. Herdman, F.R.S., Professor of Oceanography in the University of Liverpool, delivered the presidential address, his subject being "Oceanography." After reference to the founders and pioneers of the "science of the sea" he outlined some of the investigations and problems which had appeared to him to be of fundamental importance, of economic value, and of general interest. "We can," he said "scarcely hope in European seas to add new food-fishes to our markets, but much may be done through the co-operation of scientific investigators

of the ocean with the Administrative Departments to bring about a more rational conservation and exploitation of the national fisheries."

During recent years one of the most important and most frequently discussed of applications of fisheries investigation had been the productivity of the trawling grounds, and especially those of the North Sea. It had been generally agreed that the enormous increase of fishing power during the last forty years or so had reduced the number of large plaice, so that the average size of that fish caught in our home waters had become smaller, although the total number of plaice landed had continued to increase up to the year of the outbreak of war. Since then, from 1914 to 1919, there had of necessity been what might be described as the most gigantic experiment ever seen in the closing of extensive fishing grounds. It was still too early to say with any certainty exactly what the results of that experiment had been, although some indications of an increase of the fish population in certain areas had been recorded.

It had been shown by Johnstone and others that the common edible animals of the shore might exist in such abundance that an area of the sea might be more productive of food for man than a similar area of pasture or crops on land. A Lancashire mussel bed had been shown to have as many as 16,000 young mussels per square foot, and it was estimated that in the shallow waters of Liverpool Bay there were from 20 to 200 animals of sizes varying from an amphipod to a plaice on each square metre of the bottom.

From these and similar data it was not difficult to calculate totals by estimating the number of square yards in areas of similar character between tide-marks or in shallow water.

Countings and weighings, however, did not give them all the information they needed. It was something to know even approximately the number of millions of animals on a mile of shore, and the number of millions of tons of possible food in a sea area, but that was not sufficient. All food-dishes were not equally nourishing to man, and all plankton and bottom invertebrata were not equally nourishing to a fish. At this point the biologist required the assistance of the physiologist and the bio-chemist. Dr. Johnstone had already shown how markedly a fat summer herring differed in essential constitution from the ordinary white fish such as the cod, which was almost destitute of fat.

Professor Brandt, at Kiel, Professor Benjamin Moore, at Port Erin, and others had similarly shown that plankton gatherings might vary greatly in their nutrient value according as they were composed mainly of Diatoms, of Dinoflagellates, or of Copepoda. And, no doubt, the animals of the "benthos," the common invertebrates of our shores, would show similar differences in analysis. It was obvious that some contained more solid flesh, others more water in their tissues, others more calcareous matter in the exoskeleton, and that therefore weight for weight they might be sure that some were more nutritious than the others; and that was probably at least one cause of that preference they saw in some of our bottom-feeding fish for certain kinds of food, such as polychaet worms, in which there was relatively little waste, and thin-shelled lamellibranch molluscs, such as young mussels, which had a highly nutrient body in a comparatively thin and brittle shell.

His object in referring to these still incomplete investigations was to direct attention to what seemed a natural and useful extension of faunistic work, for the purpose of obtaining some approximation to a quantitative estimate of the more important animals of our shores and shallow water, and their relative values as either the immediate or the ultimate food of marketable fishes.

"To attain to an approximate census and valuation of the sea—remote though it may seem—is," he said, "a great aim, but it is not sufficient. We want not only to observe and to count natural objects, but also to understand them. We require to know not merely what an organism is—in the fullest detail of structure and development and affinities—and also where it occurs—again in full detail—and in what abundance under different circumstances, but also *how* it lives and what all its relations are to both its physical and its biological environment, and that is where the physiologist, and especially the bio-chemist, can help us. In the best interests of biological progress the day of the naturalist who merely collects, the day of the anatomist and histologist who merely describe, is over, and the future is with the observer and the experimenter animated by a divine curiosity to enter into the life of the organism and understand how it lives and moves and has its being."

In conclusion, he appealed to the population of these islands, a maritime people who owe everything to the sea, to become better informed in regard to our national sea-fisheries, and take a more enlightened interest in the basal principles that underlie a rational regulation and exploitation of these important industries. "National efficiency depends to a very great extent upon the degree in which scientific results and methods are appreciated by the people, and scientific investigation is promoted by the Government and other administrative authorities. The principles and discoveries of science apply to aquiculture no less than to agriculture. To increase the harvest of the sea the fisheries must be continuously investigated, and such cultivation as is possible must be applied, and all this is clearly a natural application of the biological and hydrographical work now united under the science of Oceanography."

COLLOIDAL FUEL.

By George Howell, F.G.S., F.R.G.S.

In following up the suggestion made by Mr. Arnold Lupton, and the editorial note which appeared in your issue of August 13th, I would like to add a few remarks.

The mixed system of coal and liquid fuel combustion is now becoming an important investigation, in view of the absolute necessity to conserve both oil and coal and to make wastage a thing of the past.

It has clearly been demonstrated, over and over again, that in combination the combustion of these two fuels is not only possible but has been put to practical test and economic use in the navies of the world and in many engines of modern type. Coal-dust we know produces a better combustion, while with oil the heat is better utilised. M. Bertin says: "Where 5 kilos. of coal would ordinarily develop each 7,800 calories, they will produce 9,200 calories, a gain of 7,000 calories. The excess of air supplied with the 5 kilos. of coal would be 20 cubic metres, and this would suffice for the added kilogram of oil, and produce 11,000 calories with no further air supply. A total of 18,000 calories compared with the original output of 7,800 calories per kilo. of coal, makes the ratio of oil to coal appear 2·31." This ratio is important when considering storage, as economy in ship-space is also a serious consideration.

Obviously coal-dust and oil in combination establish great economic possibilities, not only in efficiency but in conservation of both fuels. It is also obvious that applied air constitutes a "fuel" in itself. This is illustrated in the Bessemer steel process used for the manufacture of cast steel.

The convertor, mounted on trunnions, when in operation, is tilted down almost to an horizontal position, when the hot metal is received from the cupolas. It is then tilted back to its original, vertical position. Immediately on adjustment of vertical position, high-pressure air currents are passed through the mass from tubes placed in the bottom of the convertor; the temperature is thereby very materially increased without the use of other fuel. The point here is that when a certain temperature has been reached, the air properly conducted constitutes a fuel in itself. The open door of a furnace, however, especially in marine engines is not only an enemy to maintaining temperature but is injurious to the tubing of the boiler. It, therefore, follows that until coal-dust can be fed by fan-blast, in fixed proportion of air and coal-dust, thereby maintaining a uniform temperature and a maximum efficiency of heat-units, coal-dust cannot be a substitute for oil and coal acting in combination.

During the current year the establishing of a perfect fuel in colloidal form is to engage the attention of the Institution of Petroleum Technologists, and serious research work is now being carried on to effect economies in, and also to conserve, petroleum and coal.

On the 16th November next, at 5.30 p.m., Mr. Lindon W. Bates is to read a paper on "Colloidal Fuel" before the members of the Institution of Petroleum Technologists, and on that occasion the Council offer a welcome to all Fellows of the Royal Society of Arts.

ALGERIAN PHOSPHATE INDUSTRY.

The Algerian phosphate deposits are situated in the Department of Constantine, the most important being at Djebel-Kouif in the region north-east of Tébessa, exportation taking place principally from Bône and to some extent from Bougie.

The phosphate industry, in common with the mining industry in general, was adversely affected by the war through the reduction in personnel and working force, the impairment of the railway service, the scarcity of tonnage, the intense submarine campaign in the Mediterranean during the latter part of the war, and the loss of various European markets.

Before the war Germany was the best customer for the Algerian phosphates, taking 118,464 metric tons out of a total exportation in 1912 of 377,601 metric tons. In 1916, exports reached the highest point during the war, amounting to 322,533 metric tons. Spain took the largest share, followed by Great Britain and Italy. Owing to the various obstacles above mentioned, exportation in 1918 was less than half that of 1913. Official statistics give the following figures of the exports of phosphates in 1912-1918:—

	Metric tons.
1912	377,601
1913	438,601
1914	355,140
1915	225,868
1916	322,533
1917	234,825
1918	198,539

It is thought that the phosphate industry will take on new development, as the intensification of agricultural effort in the countries that were at war will create a large demand for Algerian and Tunisian phosphates.

Two important factors in the development of this industry, writes the United States Consul at Algiers, are the improvement of railways and of methods of extraction. Railway amelioration will require considerable time. An illustration of the new development in production is given by the Compagnie des Phosphates de Constantine, which is by far the largest concern now engaged in the phosphate industry. This company has recently set up in its establishment at El-Bey, near Tébessa, a new factory, which produces 100 tons of phosphates per hour. This factory is said to have the largest capacity in the colony, being provided with the latest equipment to economise labour and coal. The phosphates are, in fact, sorted, crushed, pulverised, dried, and put in storage or loaded on railways trucks entirely by mechanical means. The plant has storage facilities for 55,000 tons, one operator only being necessary for loading and unloading.

Owing to the transportation difficulties, the chemical producing establishments at Oran have had to close. Last year the Government limited to 16,000 metric tons the quantity of phosphates put at the disposition of the Algerian factories on account of the insufficient means of transportation.

There are three plants for the production of sulphuric acid and superphosphates in Algeria, situated at Oran, Maison Carrée (near Algiers), and Bône. These factories could produce 86,000 tons of superphosphates annually, which would exceed the requirements of the country and leave a balance for export.

OBITUARY.

Maurice George Carr Glyn.—Mr. Maurice George Carr Glyn, partner in the banking firm of Messrs. Glyn, Mills, Currie & Co., died at his residence, Albury Hall, near Bishop's Stortford, on August 21st. Born in 1872, he was the second son of the late Hon. Pascoe Charles Glyn, M.P., and grandson of the first Lord Wolverton. He was a Justice of the Peace for Hertfordshire and Middlesex, and occupied the office of High Sheriff of the former county in 1912. He was a director of the London and Brazilian Bank, the Liverpool and London and Globe Insurance Company, Messrs. Dalgety & Co., Ltd., and other companies. He was elected a life fellow of the Royal Society of Arts eight years ago.

GENERAL NOTES.

Department of Scientific and Industrial Research.—The following Research Associations have been approved by the Department as complying with the conditions laid down in the Government scheme for the encouragement of industrial research and have received licenses from the Board of Trade:—British Boot, Shoe and Allied Trades Research Association, Northampton; British Cotton Industry Research Association, Manchester; British Empire Sugar Research Association; British Iron Manufacturers' Research Association, Manchester; Research Association of British Motor and Allied Manufacturers; British Photographic Research Association; British Portland Cement Research Association; British Research Association for the Woollen and Worsted Industries, Leeds; British Scientific Instrument Research Association; Research Association of British Rubber and Tyre Manufacturers; Linen Industry Research Association, Belfast; Glass Research Association; British Association of Research for Cocoa, Chocolate, Sugar Confectionery, and Jam Trades; British Non-Ferrous Metals Research Association, Birmingham; British Refractories Research Association; Scottish Shale Oil Scientific and Industrial Research Association, Glasgow.

Dairy Industry in South Africa.—The dairy industry in South Africa has now assumed a position of considerable importance. Whereas a few years ago very large quantities of butter and cheese were imported, during the twelve months 1916-17, according to *Production and Export*, not only was sufficient butter made in the Union for all local requirements, but a surplus of over 4,000,000 lb. was exported overseas. The production of cheese during the year 1917 also increased rapidly, and large quantities have been sold and exported. The Union may therefore now be said to be self-supporting as regards butter and cheese, while there is every prospect of a remunerative export trade developing in both commodities. Experience has thus shown that a very considerable portion of the Union was well adapted to dairy farming. The climate is mild, and cattle thrive well on the natural veld from six to eight months of the year. Dairying is no longer looked upon as a side-line by farmers; large numbers are now specialising in dairy-farming and improving their cattle, with a view solely to increasing their output of milk and cream, while the arable portions of their farms are devoted entirely to the production of foodstuffs for the feeding of their cows. The principal crops grown for the feeding of dairy cattle are mealies, lucerne, oats, teff-grass, millet, mangolds, rye, and cow-peas, all of which do well in most of the areas devoted to dairy-farming. Considerable quantities of mealies are grown for silage and mealie hay, the use and value of which are being increasingly realised. It may be said with confidence that the outlook for the dairy industry in South Africa is very bright, and if the present rate of progress is maintained a great future is assured.

Black Sea to North Sea and Baltic Waterway.—The Prague Government, according to the *Marine Journal* (U.S.A.), is about to embark upon a large scheme of inland navigation. The Peace Treaty granted the Czecho-Slovak Republic free transit on the Elbe and Oder to Hamburg and Stettin, where Germany is to accord free port facilities. It has now been decided to canalise the middle Elbe and to connect it with both the Danube and the Oder. Czecho-Slovakia will then be traversed by a waterway reaching from the North Sea and the Baltic *viâ* the Danube to the Black Sea.

Shipbuilding on the Straits of Magellan.—The largest vessel built on the Straits of Magellan was launched recently at the yards of La Sociedad Ganadera Gente Grande, a Chilian company under English management, at Puerto Harris, Isle of Dawson. According to the American Consul at Punta Arenas, it is a wooden gas-screw schooner of 900 tons displacement, and is equipped with two motors of a combined capacity of 200 h.p. The vessel has a length of 142 ft., a beam of 28 ft., and a draft of 12 ft. All the wood used in its construction was cut on the Isle of Dawson. The schooner will be operated by La Sociedad Ganadera Gente Grande, which is extensively engaged in sheep farming as well as in lumbering and boat-building. This concern recently built two lighters for use in connection with a meat-freezing plant at Santa Cruz, Argentina. A wooden steamer of 125 tons capacity has been built at Punta Arenas for a local firm. It will be used in Straits traffic.

CANTOR LECTURES.

THE ARCHITECTURE AND DECORATION OF ROBERT ADAM AND SIR JOHN SOANE, R.A. (1758–1837).

By ARTHUR T. BOLTON, F.S.A., F.R.I.B.A.,

Curator of Sir John Soane's Museum.

Lecture II.—Delivered May 10th, 1920.

I propose to deal in this second lecture with a brief selection of some of the principal Adam houses, more particularly with reference to their interiors, in a sequence of dates.

It is impossible to do more than merely outline a few of the principal points in each case, and I can only refer you to the two folio volumes, now in the press, in which I hope to give a full and adequate survey of the vast subject of the work of that gifted and versatile artist, Robert Adam.

Hatchlands.—At Hatchlands, near Guildford, in Surrey, in a very dull house, reminiscent of the old Admiralty, without, however, any portico, Robert Adam made his first essay in interior decoration following upon his return from his grand tour in January, 1758.

Ripley, the carpenter, who was the architect of the Admiralty in 1724–6, was probably that of Hatchlands as well. He died February 10th, 1758, less than a month after Robert's return.

As Admiral Boscawen (1711–1761), the hero of the capture of Louisburg (1758), returned in November of that year and sailed again on April 14th, 1759, the date of the Adam drawings can best be placed quite early in the latter year.

The Admiral's monument in Cornwall states that he had just finished the work at his death, January 10th, 1761, and less than two years would be little enough time for the execution of the Adam work at Hatchlands. Robert's share must be confined to the completion of some of the chief rooms. Naturally the work is unrestrained in design and seems bursting with all the enthusiasm of a recent return from Italy. The actual work is better than the drawings, and the design evidently underwent a process of revision in execution, though one less chastened than would have been the case after even a brief experience on the designer's part of actual work.

The centre room of the chief front, the present Great Drawing Room, is the interior with which the principal Adam drawings that remain are concerned. The ceiling is centred on an oval, enclosed by the strong lines of a prolonged octagon, with an outer border enlivened by sea horses in relief. The concentration of ornament in the corners is an Italian feature. The walls are simply framed up into panels, which in Adam's drawing are filled in with arabesques in stucco, of the type of those which exist at Shardeloes. Two paintings of ruins are shown in the centre panels, with a subject-piece enclosed in the overmantel frame. The fine white marble mantelpiece displays a pair of tall graceful figures, a composition which was Robert Adam's earliest ideal. The adjoining Library has even more character. The scheme of the ceiling seems to have a personal reference to the hero's career. The set-out is a radiating scheme of panels with an effect rather resembling that of the gussets of an octagonal dome. The four main figures in these spaces are Neptune, Justice, Fame, and Victory, the last being a figure with a laurel wreath and palm branch. The alternating panels are filled in with twin mermaids rising from a base of cannons, rifles, anchors, flags, swords, spears, and even drums, a mass of decorative symbolism dear to the heart of the eighteenth century. The whole design has evidently a monumental significance and symbolic intent.

The mantelpiece in white marble, of which the drawing exists, is interesting as an early example when Adam was disposed to follow massive architectural types.

There was a great salon upstairs which no longer exists. The ceiling was based on a great oval, the band of which was filled in with octagonal coffering.

The abiding interest at Hatchlands will always be that of possessing the earliest decorative essay of Robert Adam after his return from Italy.

Shardeloes.—Shardeloes, near Amersham, in Buckinghamshire, may be regarded as the first house, though here also some building work was already in hand, before Adam came on the scene.

The interiors of this house illustrate the claim, made by Robert Adam in his preface to the "Works" of 1773–8, to have effected a revolution in the taste of the age:

"In the decoration of the inside, an almost total change, the massive entablature, the ponderous compartment ceiling, the tabernacle frame, almost the only species of ornament formerly known in this country, are now universally exploded, and in their place we have adopted a beautiful variety of light mouldings, gracefully formed, delicately enriched, and arranged with propriety and skill. We have introduced a great diversity of ceilings, friezes and decorated pilasters, and have added grace and beauty to the whole, by a mixture of grotesque stucco and painted ornaments, together with the flowing *rainceau*, with its fanciful figures and winding foliage."

Shardeloes represents, of course, the origination rather than the full accomplishment of these ideas. As an early work it has a strong hold on what had gone before, with all the fresh interest added of the germinating stage of a new manner.

In the interiors we see the heavier and bolder ornamentation of the beginner, who has not yet shaken himself free of the earlier Georgian style. The wild curves and scrolls of leafage, in this preliminary essay at Shardeloes, as also in the first Adam designs executed at Kedleston, had yet to be subdued and harmonised into a new system of low relief decoration of a classical and restrained architectural character.

The wall decorations of the Dining Room are perhaps the most symptomatic achievement at Shardeloes, work which seems to call for less of the taming process than the ceilings throughout the house, which very probably were the first work executed. In these wall panels the sphinxes and the inserted bas-reliefs, which were to form the central *motifs* of his system, already appear and strike the true Adam note. The finish and delicacy of the later work are indicated rather than achieved at Shardeloes.

The house interiors remain here seemingly the same and untouched. The wall colourings are now faded to pleasant tones of green, lilac, and grey, while the ceilings are mostly white.

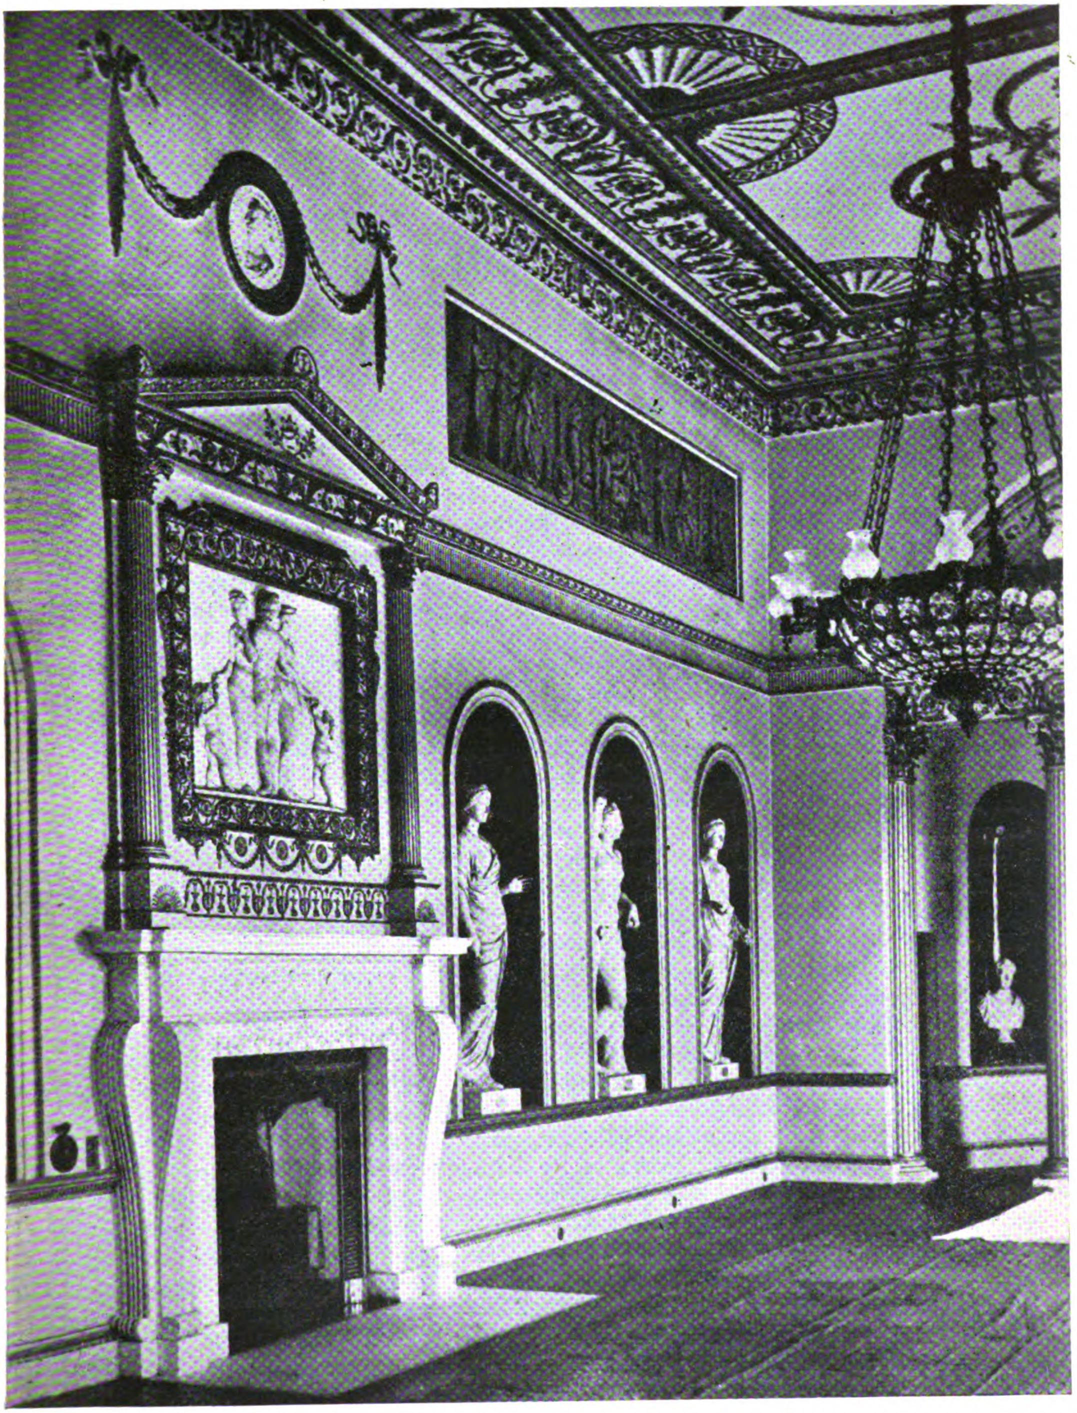
The doors, double owing to the thickness of the walls, are magnificent specimens of mahogany, aged to the colour of a tawny port wine, and dulled in polish to a delightful surface.

The Salon, entered from the great portico in the centre of the east front, is a stately hall in that form of Doric, which Adam afterwards developed so effectively at Lansdowne, Harewood, and many another of his great houses.

The Dining Room at the northern end of the east front is a fine interior, richly decorated. The ceiling has a large oval band crossed by very free-flowing foliage, like a chain of wreaths. The crossed thyrsi and the ivy in the centre are an obvious reference to Bacchic rites. As a whole this design suffers from heterogeneous effect of elements insufficiently welded together. Adam, more than once, using the same idea, hereafter effected great improvements on this early composition.

The Drawing Room, in cream colour, contrasts with the faded blue of the Salon. Relief is afforded by two fine mirror frames in gold on gilded console-tables with quadrant tops of scagliola. The ceiling presents a central circle with four lions' heads linked together by bold swags. Four fans are introduced, features which Adam afterwards developed with great effect. Here again the somewhat wild scrolling on the ceiling illustrates the early date of the work.

The Library, occupying the centre of the south front is perhaps as characteristic as any of these interiors. It may be regarded as the first of those rooms, dedicated to books, of which he produced so fine a series. The distribution of the south window-wall takes the form of a shallow arcade, the bookcases being worked in as projections on the piers. The other walls are entirely lined for two-thirds of their height with white painted deal casings framing up wire panel doors, behind which the books are visible. The entrance doorways to the room are brought into the scheme, so that the line of the book casing is preserved throughout. Above are a series of panels filled in chiaroscuro paintings on green grounds, like a Wedgwood cameo relief on a large scale. The fine mantelpiece is of white marble with Sienna yellow insertions. It has long fluted consoles and a vase in low relief on the central panel of the frieze.



Syon House. Fireplace in Dining-Room.

Harewood.—The Adam drawings for the interior of Harewood, in Yorkshire, form an important group of designs all dated 1765. The carcase of the house had been in progress from about 1760, John Carr, of York, being the local architect on the spot working in conjunction with Adam, more particularly in reference to the exterior and the plan, which both represent a compromise between the older tradition and Robert Adam's newer ideals. Adam's plans and elevations for interiors at Harewood occupy many sheets of drawings, and show more work even than was ever realised. They cover the whole of the interior, and include accessory buildings, which do not appear to have been built. Each room is shown by a separate sheet, giving a detail plan, with the four elevations of the walls drawn round it. The correspondence of these drawings with the actual work shows that extraordinary fidelity which astonishes us in Adam's executed works. The detail can be authenticated by the photographs I have had taken in all cases, proving that what Robert Adam designed was faithfully produced.

Many alternative first and second designs exist, but once the drawing was approved, the work seems henceforth to have been carried through exactly as it was shown by him. It is a great testimony to the confidence that was placed in Adam, and to his own power of realising his intentions. The Hall at Harewood is on a large scale and, though less imposing and masterly than that of Syon, is yet a monumental example of Robert Adam's work. The bold engaged columns, though unusual with him—he habitually used pilasters—are shown as of fully three-quarters' projection in his original design. The main feature of each wall is emphasised by an arch; in particular opposite to the entrance doorway was a deeply recessed archway with niches, which has since been filled up on the Hall side. The ceiling of the Hall is flatly treated with a central octagonal feature. On the walls are medallions and panels, and on the flag in one of them is the date 1767, which will be that of the completion of this interior, as the drawing for the Hall is dated 1765, and for the fireplace 1766.

The Music Room, entered on the right, is a fine Adam interior still possessing the original carpet, which reflects the design of the ceiling. The medallions on the walls are ascribed to Angelica Kauffmann, and the landscapes to Zucchi, while the portrait of the first Earl of Harewood, in an Adam frame, is by Hoppner. It should be noted that all Adam's drawings for the furniture at Harewood are missing. It is probable that they went direct to Chippendale, and were not returned.

The Great Gallery has been altered; the chimney piece has been moved to the Dining Room. It is a fine instance of the early type of a pair of tall graceful women. The frieze and enclosing mouldings were of ormolu, with a purple ground to the bas-relief panels. The figures were united by light and graceful swags.

The fine ceiling of the Gallery was carried out by Rose from a large coloured drawing by Adam dated 1769. It is exceedingly good in relative scale and ingenious in pattern.

The curtain boxes to the windows are characteristic, and the pendant valences, carved by Chippendale in wood, are so skilfully executed as to quite deceptively match the deep blue colour, as well as the fabric of the curtains.

This doubtless was so arranged to obviate the bad effect of the dust and corrosion of any woven material at that height.

The window piers have magnificent console-tables with mirrors over them. The latter follow a design, made by Robert Adam for Sir Lawrence Dundas in 1765, with interesting modifications of detail. The white marble tops have coloured inlays and gold framings. The ovals above were painted by Angelica Kauffmann.

The Salon in the centre of the south front has been altered by book-casings. Adam had placed screens of columns across the apses, with a pedimented doorway as a centre between them. The pair of splendid mantelpieces on the two side walls remain complete with their overmantles in exact accordance with his drawing. The centre composition which he shows is a "Sacrifice."

A tourist, writing in 1787, says: "All the rooms are equally elegant and costly, but the large Gallery and the Great Drawing Room present such a show of magnificence and art, as the eye hath scarce seen.... The Great Drawing Room is as handsome as designs and gilding can make it; here are seen elegant glasses, ornamented with festoons, particularly light and beautiful; also tables with same. The whole has been furnished only a year by Chippendale, of St. Martin's Lane."

The lesser Drawing Room was apparently an Etruscan room.

Croome Court, in Worcestershire, and *Bowood*, in Wiltshire, both present Adam work of the early period, but in each case they are alteration and decoration work to buildings, erected mainly by others, and need not be discussed here.

Syon House. Ceiling in Dining-Room.

Kedleston, Derbyshire.—James Paine tells us that in 1761 he prepared the designs for Kedleston which appear in his book. This vigorous but rather heavy-handed architect enjoyed a great reputation and an enormous practice in the North of England. His scheme was to build a centre block with four detached wings, connected by quadrant corridors treated as colonnades. The plan was never completed, and only two wings with their connections exist.

He says that he accepted the previous design of Brettingham for the four wings, but himself "planned the centre block and connecting corridors."

This bears out a memorandum by the first Lord Scarsdale, recording that he built the house between the years 1758–68, and makes it probable that Brettingham was the first architect.

Adam's earliest drawings relate to carpets and ceiling designs, and it would appear most probable that, at first, he was to complete the interior. He appears to have been already working in association with Paine at Alnwick.

The most marked feature of Paine's centre block was a great columned hall and a circular salon, between which he proposed to place the main staircase of the house. Subsequently, however, according to his own account, finding himself too busy in other parts of England to devote to the proposed building the close attention which so great a work required, he requested to be allowed to resign the task, "whereupon it was entrusted to those able and ingenious artists, Messrs. Robert and James Adam."

In point of fact he was very much preoccupied with Worksop, which had just been burnt down (October, 1761) a month after its completion.

From all this we may assume that Lord Scarsdale had lost faith in the scheme propounded by Paine, and that Robert Adam was called in to complete and particularly to decorate the structure.

Adam revised the plan by suppressing the great staircase, by which change of plan the idea of a great villa in the antique manner was better realised. The bedrooms above were purely secondary, and a minor staircase was all that was required. A grand suite of unbroken state apartments on one level was thus secured.

It is evident from the external appearance of Kedleston that the elegant centre of the south front is entirely due to Robert Adam. It was a part only of a fine and characteristic composition. Had Adam's design been carried out this front would have been complete in itself, and would have illustrated his principle of "movement," as expounded in the prefaces to his "Works."

The large original Adam drawings in the Soane Collection show that the north façade has merely been revised by him, the circular medallions under the portico being, for instance, added. Except, in fact, for a few minor details and a superior air of refinement, this front agrees with Paine's élevation.

The interior of Kedleston, however, is obviously entirely by Adam, and it is of remarkable interest, because it is a development of the work at Shardeloes, and is also closely related to the great interiors of Syon, which were in progress at the time.

Of the thought and labour that Robert Adam gave to Kedleston there is remarkable evidence. Folios of designs in colour and pencil, some of which were used, while others remain as studies, exist. Every detail was brought into the scheme, furniture, grates, fire-irons and fenders, all testify to the thoroughness and comprehensive character of his work as an architect.

The Salon, or Rotunda, into which the Great Hall leads, is remarkable for its successful proportion. It is forty-two feet in diameter and fifty-five feet high, with four alcoves in extension of each plan, each eleven feet across and twenty-two feet high. The usual size of Adam rotundas is about thirty feet.

The coffered dome is very pleasant in scale and treatment, and there is great charm in the lighting effect.

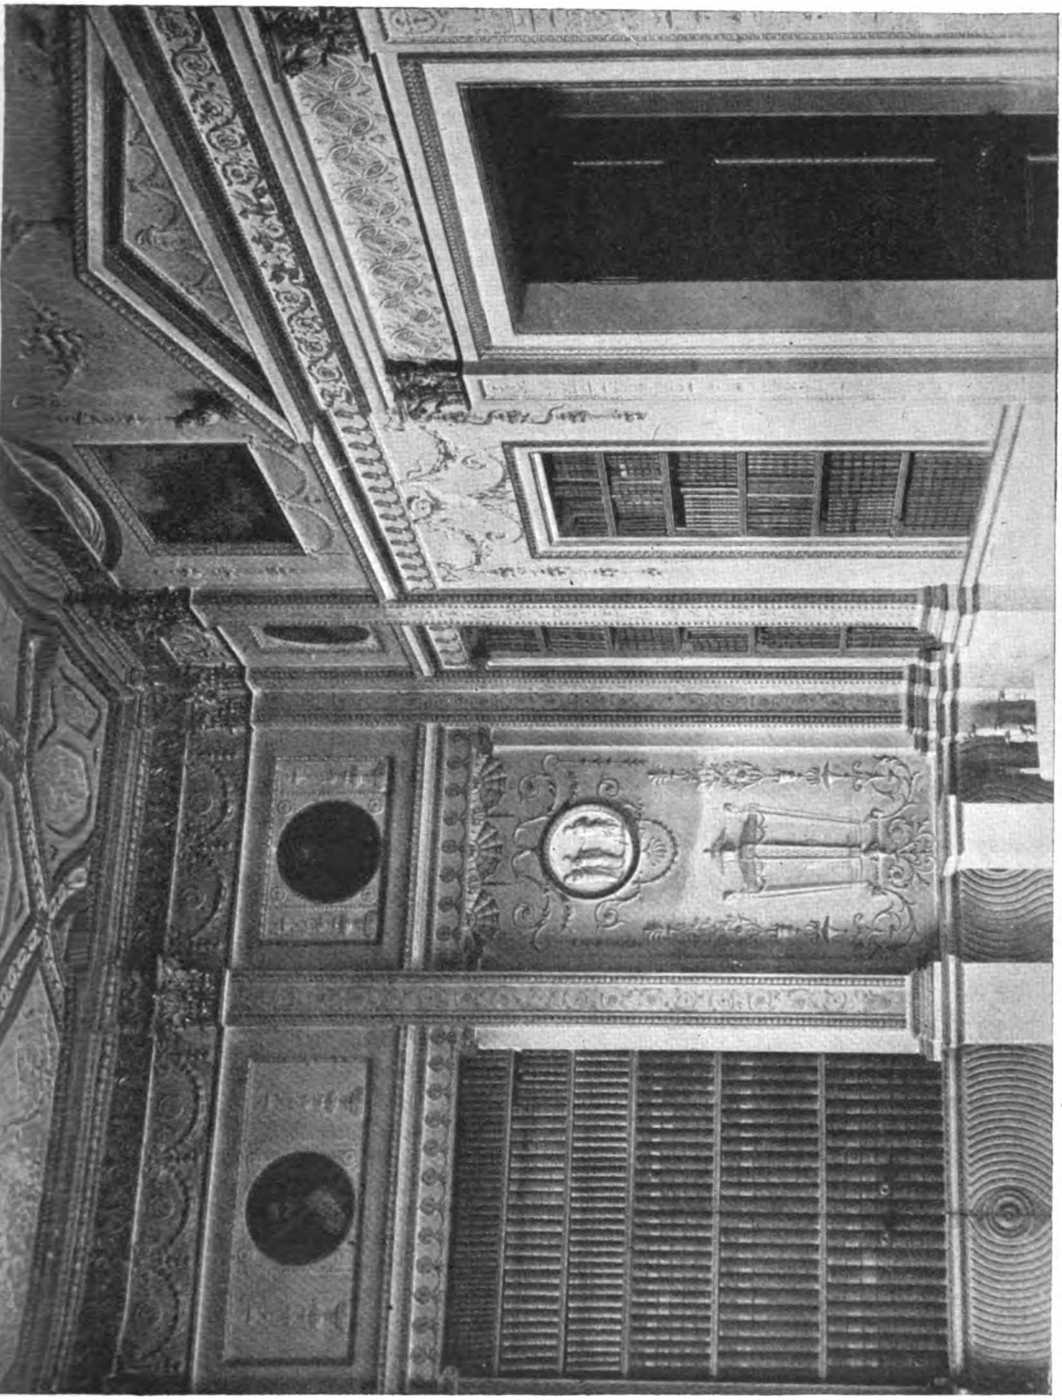
The decorative tablet panels surmounted by candelabra on the walls are notable pieces of stucco work. The minute amorini are polished to a marble surface and relieved by a dull red background and gilded frames. The striking cast metal altars, and vases in the alcoves, were connected with the hot air scheme of heating employed by the Adams in these rotundas.

The Great Hall and Salon lead on the right into the Dining Room, where Adam's attention to detail is conspicuous in the treatment of the alcove, which is flanked by two doorways of exquisite finish.

The ceiling is planned to receive landscapes by Zuccarelli and Zucchi. Other panel pictures decorate the wall.

On the left of the Hall and Salon is the music room, which contains an interesting organ case, richly gilt but simple in design. Adam's original design was far more elaborate. The white marble chimney piece is inlaid with blue-john.

The Great Drawing Room, which was originally hung with blue damask, has a coved and richly



SYON HOUSE. DETAIL IN GALLERY.

decorated ceiling. It follows closely a design dated 1760. The freedom of the decoration is reminiscent of the earlier Adam work, as at Hatchlands.

The mantelpiece, with a pair of tall figures, follows the ideal set at that house and at Croome.

The Venetian window, the columns and pediment of which, like the doorcases, are of Derbyshire alabaster, is remarkable for its scale and planning, by which an effect of great depth and richness is obtained.

The furniture of this room is of interest. Alongside of beautiful tables and mirrors, essentially typical of his style, are four massive sofas with elaborately carved and solidly gilt merfolk, mingled with dolphins and palm leaves, quite Venetian in taste, which contrast curiously with the lighter and more delicate devices for which Robert Adam was famous.

We are reminded of Adam's comment, when publishing the plate in the "Works" of the Empress Catherine's piano:—"This design was much altered by the person who executed it." Adam's drawing in the Soane Collection for the sofa, signed "R. Adam, architect, 1762," shows how the architectural limits he observed have been overpast.

Mrs. Montagu had a similar sofa, according to the note on the drawing, but with a different colouring in the upholstery, one design being red and the other green.

Her sofa, however, must have been executed in a style severely classic, so as to accord with the beautiful mantelpiece, which Adam also designed in 1766 for her house in Hill Street.

In the Library, unlike the other apartments on this floor, the Doric pillars and the entablature of the doors are in wood, and are somewhat heavy in scale and treatment. The ceiling is decorated in tints of blue, pink, and mauve. The chimney-piece agrees with Adam's drawing. The State Boudoir and its Ante-room are separated by a screen of columns and pilasters, grouped in relation to a segmental archway, late Roman in style.

In these rooms there is less of the early Georgian influence which Adam had set out to reform, and a lighter scheme of decoration and furnishing prevails.

The subsidiary buildings in the grounds and the great bridge are fine examples of Adam's treatment of accessories to his main group.

Syon House.—The plan of Syon in the "Works" bears the date 1761, which will be the time when Adam's connection with the work began. His own statement, however, gives 1762 as the year in which the Duke of Northumberland resolved to fit up the apartments "entirely in the antique style." Adam says "the idea was, to me, a favourite one, the subject great, the expense unlimited, and the Duke himself a person of extensive knowledge and correct taste in architecture."

Adam had just completed Shardeloes, and resemblances can be traced between the details employed there and those used in the earlier rooms at Syon. For instance, the ceiling of the Dining Room is closely related to that of the Library at Shardeloes.

The work must have been in progress many years, as one of the carpets is dated 1769, and the whole of the intended scheme was, even so, never realised, as the most important feature of the plan, the central rotunda, was not executed. This salon was needed to bring the entire suite to a focus and connect together all the apartments, serving, in Adam's own words, "for general rendezvous, and for public entertainments with illuminations, dancing and music." Apparently, in September, 1768, this rotunda was temporarily erected for the reception given to the King of Denmark, when 300 persons were entertained in the room, "without the least bustle."

Adam himself defines the position he had to deal with, in creating this magnificent suite of rooms at Syon within the existing walls of the house. "Some inequality in the levels on the old floors, and some want of height to the enlarged apartments were," he says, "the chief difficulties with which I had to struggle."

Entering at once the Great Hall, the full grandeur of his conception is realised. This interior, in a creamy white with a black and white marble floor, realises the classic ideal of pure form and restrained ornament.

Late in the afternoon the western sunlight strikes down from the upper range of windows, producing a wonderful effect of light and shade. The size, 60 ft. by 30 ft. by 30 ft., is about that of the great room at Wilton, but no greater contrast between the two interiors can well be imagined, and we realise at once how much has happened in the intervening century. The problem of the dimensions is solved by Robert Adam on entirely different lines to those followed by Inigo Jones. He reduces his length by a great apse at one end, and a square recess at the other, the latter having a screen of columns. The connecting walls have each five windows and a door. Such are the simple elements out of which this fine interior has been evolved.

The highly original ceiling with its large crossed

beams, doubtless arose from his wish to reduce the excessive height of the bare structure, and the idea is worked out with great skill.

A broad band of ornament frames the central oblong and ties the whole design together. The disposition of the floor follows that of the ceiling. It is doubtful if Adam ever used the Doric order, which he preferred for halls, with better effect.

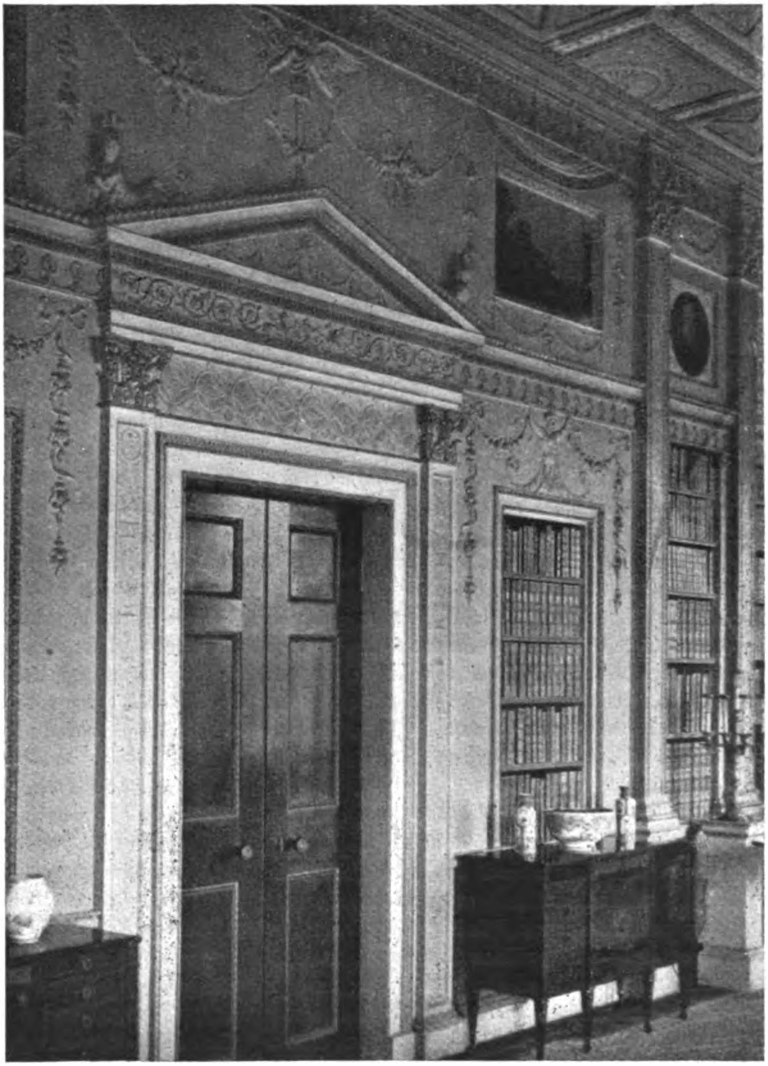
The steps, which were necessary to reach the principal floor level at both ends of the Hall, are so cleverly worked in that they seem an additional charm, rather than a difficulty overcome.

To step up from the Hall to the Anteroom is to pass into another world. It is Rome of the most lavish epoch of the Empire, when the world's wealth poured as a great river into the all-powerful metropolis. Colour reigns supreme with a predominance of solid gilding. The keynote has been twelve ancient columns of verde-antique, recovered from the bed of the Tiber. To these shafts Ionic capitals solidly gilt have been added, with a new entablature, in which the frieze is decorated with a honeysuckle in gold on a bright blue ground. The walls are pale green with doors in dark mahogany and gold. Green bronze is also used in the bas-relief over the fireplace.

The floor is a remarkable piece of scagliola, very highly polished, and marvellously preserved. The colours are yellow, bright and dark red, reaching to chocolate, and a peculiarly soft greenish grey, relieved by some actual blue.

The architectural interest of the room centres in the very clever arrangement of the twelve columns, as the room is not really square, being 36 ft. 6 in. by 30 ft., with a height of 21 ft.

The desired square set-out is obtained by bringing forward the columns on the window side



SYON HOUSE. DOOR IN GALLERY.

and carrying across the entablature, the vertical line being maintained by statues upright on the columns. Thus the room is square in effect with the minimum loss of floor space.

Entering the Dining Room we leave colour behind us and return to an effect of white, but in a warmer tone and with a free relief from gilding. This room would seem to be one of those first completed at Syon. Each end of the

room has an apse with a screen of columns across it, and the half domes are well ornamented but without the extreme beauty of those at Kenwood. A flat band carried round the room, level with the top members of the cornice of the order, connects the end and side walls, a treatment favoured by Adam.

With the Red Drawing Room colour again resumes its sway. The walls are hung with Spitalfields silk, in which the pattern of flowers and ribbons in grey shimmers like silver on a plum coloured ground. The ceiling has a deep cove, which, together with the central flat, is all set out in octagons and diamonds, rather small in scale. These have been painted with figures by Angelica Kauffmann, too small for their position, and, in addition, so emphasised by bright blue grounds, as to produce a spotty effect, which is somewhat distracting. The Adam carpet is of a good and restful design, the colours pink and yellow with some blue, all now very harmonious. It is dated "1769, T. Moore."

The two doorways are remarkable for the ivory grounds to the pilasters, which are overlaid in ormolu.

The white statuary marble mantelpiece is a masterpiece of applied ormolu. The enrichments are chased and perforated frets, appliqués, even the flutes of the columns have tiny strings of beads which are attached to the fillets between the flutes. The rosettes, swags, and even the dentils are of the same metal. It is like an overdress of gold lace thrown upon the white marble form.

This drawing room is Adam's Ante-room to the real Withdrawing, or Ladies', Room, the gallery, which he planned for their particular delight. "Furnished in a style to afford great variety and amusement," is his own expression. It is certainly a marvellous interior, because it is the Elizabethan-Jacobean gallery seen through a different medium. The problem was the narrow width of 14 ft., with a length of 136 ft., and a height the same as the width. These are quite the old dimensions for galleries in England, and it was only the orthodox classic ideas of proportion, that seemed to make them incapable of solution. Robert Adam accordingly dealt with the problem on his own lines, not, perhaps, without some observation and reflection on the many older galleries, which he must have seen in various parts of the country. His scheme is that of a unit of four pilasters, with wide intervals or bays, centred upon the three doors and two fireplaces, so that in the perspective a sense of spacing and variety is obtained, which mitigates the great extent of the gallery in length. The opposite wall, with its eleven windows, could not be made to agree with this set-out, so it has been boldly disregarded.

The pilasters, however, are retained to frame up the windows, maintain the balance of the two sides, and give the required vertical lines in the perspective of the whole.

The ceiling is daringly set out with circles, repeated down the length of the room, and held in an octagonal framework separated by squares. Unity is obtained by cross lines, which lead the eye down the vista of the gallery with a tendency to expand its width. The wide compartments in which the doors and fireplaces occur are skilfully treated with niches and circles, and the main order of pilasters is supported by a secondary Ionic, between which the bookshelves are fitted in.

The deep frieze above the architrave cornice of this minor order is varied with landscape and portrait panels, and by some circular recesses for busts and choice vases.

The minor closets and central recess are conversational retreats. The square closet is interesting, but the gem is the circular domed boudoir, which realises the setting of an eighteenth century print, of the age of Watteau, Lancret and Boucher.

The ceiling paintings of the gallery are rather small and too pretty. The general effect of the faded pink and green of the wall decorations is good. It must all have been immensely gay when new and fresh. Of Adam design there are two pairs of beautiful tables of marquetry with carved and fluted legs and framework. One of them has a scroll pattern working from two centres, so as to fill in the oblong shape of the table top. It is inlaid in yellow and green on brown. The other has an all-over pattern. They are English made. Two half-circle console tables, carved and gilt with urns worked into the base, and bearing table tops of inlaid marble, are also of Adam design, as well as two oblong console tables, the tops of which are of mosaic.

The highly-important work at Osterley, in the same locality, while partly of the same date as Syon, also contains examples of Robert Adam's later style. Space does not allow of more than a reference here, but in the forthcoming book the house will be fully illustrated and described by the special permission of the owners. Here, as at Apsley House, English execution was made a special feature. Not only does this fact dispose of the idea that Robert Adam was merely in-

debted to and dependent on Italians, but it also confirm's Soane's statement as to the beneficial effect of Adam's influence on the arts and manufactures of the time.

Luton Hoo, for the Earl of Bute (1767–8 period) must also be passed over, though it was certainly a very important transition work and possessed probably the finest of all the Adam libraries. Unfortunately this work no longer exists owing to a fire and later reconstructions.

Kenwood, Hampstead, for Robert Adam's friend and patron, the great Earl of Mansfield happily remains.

Kenwood, is a villa design created out of an older existing house. Changes, following on the death of the great Earl of Mansfield and of his architect, have altered its character externally, the removal of the main road and the abolition of the forecourt tending to give it more the character of a country-house.

The Portico, therefore, at present cannot be said to possess its original effect, while on the garden side the decay of the original stucco arabesques has led to a replastering now devoid of the ornate character of the original.

Passing through the Hall of an Adam character, a very pleasant ante-room, lit by an end Venetian window towards the south, leads into the "Adam Room," as it is now appropriately called. This truly magnificent apartment ranks high amongst the great chambers to be found in England, and takes a leading place in the list of its architect's achievements.

Robert Adam's own account is as follows:—

"The great room with its ante-room was begun by Lord Mansfield's orders in the year 1767, and was intended both for a library and a room for receiving company. The circular recesses were, therefore, fitted up for the former purpose, and the square part or body of the room made suitable to the latter." This duality of purpose corresponded with the character of the client.

"The ceiling," Adam tells us, "is in the form and style of those of the ancients. It is an imitation of a flat arch, which is extremely beautiful, and much more perfect than that which is commonly called the coved ceiling."

"The coved ceiling, which is a portion or quadrant of a circle round the room, and rising to a flat in the centre, seems to be altogether of modern invention, and admits of some elegance in the decoration."

The eighteenth century architects, following Palladio and the Italians, had established in England the lofty *piano nobile* of Italy, and had been much exercised by the excessive height so obtained, unsuited as it was for living rooms in our northern climate. The cove as described by Adam above, is found in all the houses of the time, particularly in those of single and double cube dimensions, experiments to which the Palladian School were excessively devoted.

The State Dining Room at Bowood is a good example of the coved type, and in that instance Adam has certainly invested it with "some elegance in the decoration."

The stucco work at Kenwood was by Rose, the plasterer, who was also employed by Adam at Syon, etc. "The paintings," he says, "are elegantly performed by Mr. Antonio Zucchi, a Venetian painter of great eminence; and the grounds of the *panels* and *freeses* are coloured with light tints of pink and green, so as to take off the glare of white, so common in every ceiling, till of late. This has always appeared to me so cold and unfinished, that I ventured to introduce this variety of grounds at once to relieve the ornaments, the crudeness of the white, and create a harmony between the ceiling and side walls with their hangings, pictures and other decorations."

Here we have a clear statement of Robert Adam's ideas. His ideal of low relief in schemes of house decoration, with details of elegance and refinement, carries him on to the use of flat tones of colour, which shall give the necessary emphasis to the ornament.

It is not, properly speaking, that "picking out" method which followed later, as the style degenerated in the hands of his followers and successors. That detestable method of decoration was, however, an easy step down as soon as the Adam manner was imitated and cheapened.

A main feature of the Kenwood Great Room is the pair of apses with their screens of columns, the entablatures of which, carried straight across at the spring of the half domes, bind together the whole design of the interior. By this means an effect of perspective and some mystery of light and shade are produced.

The half domes are masterly pieces of decorative stucco work, worthy of Pirro Ligorio himself. The great vault is well set out in flat compartments varied in proportion, and adorned with ovals, half ovals and circles. These are filled in with highly-coloured paintings, executed in tones strong enough to stand the rich gilding, which forms so large an element in the whole effect. The fluted columns in white are a strong element in a successful scheme.

Continuity of design between the two apses and the centre bay is promoted by a bold

honeysuckle band at the base of the vault and of the apses.

It is a recall of the narrower frieze of the entablature where lions' and bulls' heads, the family crests, are repeated in a chain of running ornament.

The two large arched recesses on either side of the fireplace had originally characteristic Adam mirrors and settees.

The bookcases of the apses had originally solid dados.

On the piers between the windows are two mirrors in carved wood and gilded frames. These are illustrated in the "Works."

The white statuary mantelpiece has carved pilasters, bulls' heads and sphinxes. Over it is the imposing portrait of the Earl, by David Martin (1736–1798), set in a panel with a finely designed flat framework. The border which balanced the top has been swallowed up by an excess in the size of the picture.

From an account of 1776 it appears that the Hall and other rooms, except the Library, had their walls covered with Indian or Chinese papers.

The *Adelphi* scheme was launched while Kenwood was in progress. It appears to have been somewhat unfortunately undertaken, and it is unlikely that Robert Adam had any conception of the drag that it was to prove upon his promising career.

The whole subject of Adam's great influence upon the architecture of London requires a volume in itself, and with regret I have concluded that it cannot be brought within the scope of these lectures. One or two leading points may be given. *Shelburne*, now *Lansdowne House*, begun about 1762 for the Earl of Bute, was sold by him to the Earl of Shelburne in 1765, and the work of completion went on until 1768. It was in the contract of sale that the house was to be completed according to the original scheme by the Adams, the vendor sharing in the expense. This house is, of course, a very important example of Adam's work.

Mansfield Street (1770), was first planned to lead up to a great house, which was not built. The houses here follow upon the Adelphi, and contain interesting work.

Portland Place, as first intended in 1773, was to have been a *corso* of great houses. When the original idea fell through, the enterprise appears to have been left to James Adam to carry out in a much less stately and magnificent manner, 1776–78. The war time delayed the scheme of the new street, and much of it was afterwards merely a continuation by Nash, or else the work of independent builders. One of the finest of Adam town houses is *No.* 20, *St. James's Square*, but even this was less magnificent in its interiors than old *Derby House*, in Grosvenor Square, which no longer exists. An example, standing in a class by itself, is *Home House*, in Portman Square, which exhibits a late phase of Adam work. In spite of alterations in the first half of the nineteenth century, this house still gives a fine idea of the golden age of late Georgian magnificence.

Fitzroy Square (1790) was only in hand at the time of Adam's death; it was stopped by the outbreak of the great war after only two sides were built. The other two, executed quite twenty years later, show the altered temper of the times.

Of the vanished *British Coffee House*, in Cockspur Street, Soane, who, of course, knew it well, spoke in his lectures to the Royal Academy, declaring that, quite as much as the Register House of Scotland, in Edinburgh, it was a monument to the ability of its architect.

The reality of Robert Adam's influence on the architecture of the time is shown by the persistent attribution to him, personally, of a variety of the buildings of his contemporaries, whose names are practically, if not entirely, forgotten.

The city of London was least affected by his revolution, the all-pervading work of Wren, and his immediate followers, constituting a strong local tradition.

In the same way the work of Robert Adam in Scotland would here make quite impossible demands on our time and space. It must suffice to call attention to the noble *Register House* of Scotland, facing the end of the North Bridge in Edinburgh, a work remarkable for the Grecian refinement of its detail, and to the later, grand and massively simple *University*, as originally designed by Robert Adam. These will all be dealt with at length in the forthcoming book.

Unfortunately the Revolutionary Wars following Robert Adam's death in 1792 blighted the fair prospects of that great work, the University, as well as those of *Charlotte Square* (1791) with its intended church.

On the resumption of both of these undertakings after the war, by the new generation that had sprung up, the Adam tradition had already been clouded over, and the resulting work fell far short of the intentions of that great

architect of the last half of the eighteenth century, Robert Adam.

BRITISH EMPIRE FORESTRY CONFERENCE.

The resolutions passed at the British Empire Forestry Conference held in London in July last, and attended by upwards of forty delegates representing respectively the United Kingdom, Australia, Canada, India, Newfoundland, New Zealand, South Africa, the Crown Colonies, Egypt and the Sudan, have been issued as a White Paper, and are to be brought to the notice of the various Governments.

In view of the great importance to the Empire as a whole, as well as to each of its component parts, of producing a sustained yield of all classes of timber, and of encouraging the most economical utilisation of timber and other forest products, and of maintaining and improving climatic conditions in the interests of agriculture and water supply, the Conference affirms that each of the Governments of the Empire should lay down a definite forest policy to be administered by a properly constituted and adequate forest service.

The foundation of a stable forest policy for the Empire and for its component parts must be the collection, co-ordination, and dissemination of facts as to the existing state of the forests, and the current and prospective demands on them.

In order to attain continuity in the development of forest resources, it is desirable that certain elements of stability be secured in the constitution of the forest policy. This may be done by the following measures:—

1. The definition, where this has not been done already, of forest policy in a Forestry Act or Ordinance.

2. The reservation for the purpose of economic management and development of forest land under conditions which prevent the alienation of any which is primarily suitable for forests, except for reasons consistent with the maintenance of the forest policy as a whole.

3. The assurance to the Forest Authority of funds sufficient to carry out the accepted policy for a series of years.

4. The grant to members of the forestry service of the status of civil servants with due provision for pension.

5. The appointment as the chief officers of the forestry service of persons having a high standard of training in forestry, their selection and promotion being by merit alone.

6. The establishment in each of the larger parts of the Empire, and for the Colonies not possessing responsible government collectively, of an officer, or officers, having special duties of advising as to forest policy and surveying its execution.

It is extremely desirable that the Forest Authority should be in close touch and consultation with organisations representing the interests concerned in the extraction and utilisation of timber and other forest products.

The Conference have had their attention drawn to the advantages which have accrued in several parts of the Empire from the wide distribution of forest plants, and desire to bring the method of encouraging tree-planting by distribution of plants, either from Government or private nurseries, gratuitously or at cost price to the earnest attention of their Governments.

A scheme of research work received the approval of the Conference, and is recommended to their Governments for early consideration and approval. This takes the form of a report from a Committee dealing with the organisation and sub-division of research, with the relation of the different parts of research to one another and to education and practice, and with the subjects of research both generally and in relation to the needs of the different parts of the Empire.

It should, the Conference declares, be a primary duty of Forest Authorities throughout the Empire to establish systematic schemes of forestry education. It has been found, for climatic and other reasons, that it would not be possible for each part of the Empire to establish a complete scheme of forestry education of its own, and, therefore, it is essential that those parts of the Empire which are willing and able to establish complete systems should, as far as possible, frame such schemes with a view to combining for meeting the needs of those parts which can only themselves make a partial provision for their requirements.

Part of this subject has been dealt with by another Committee, whose report embodies the following principles:—

1. That one institution for training forest officers be established in the United Kingdom.

2. That students be selected from graduates having taken honours in pure or natural science at any recognised University.

3. That it be an integral part of the work of the institution to arrange supplementary courses at suitable centres for students requiring special qualifications, and also special courses for forest officers from any part of the Empire, whether at the institution itself or at centres of training in other parts of the world. The Governments should recognise these courses as part of the ordinary duties of the forest officer, at any time during their service, and the Governments concerned should give special facilities to forest officers in their service to attend such courses.

4. That a department of Research into the formation, tending and protection of forests, be associated with the training institution.

5. Encouragement should be given to the existing provision made by Universities and Colleges for forestry instruction for those who do not desire to take the full course suggested for the forestry service. It appears that this is especially applicable to the United Kingdom.

It is also desirable to make adequate provision for woodmen's schools for the training of foresters as distinct from those which are intended for forest officers.

The Conference also approved of the suggestions and recommendations for the constitution of an Imperial Forestry Bureau which are contained in the report of a committee. The delegates feel that it must be upon the work of such a Bureau that the proper development of the forestry resources of the Empire will largely depend, and they therefore, cannot over-emphasise its importance as a part of Empire organisation. The following questions should be referred to the Bureau immediately on its formation: (i) Standardisation of forest terminology; (ii) correct identification of timbers, and standardisation of their trade names. The total sum required will not be less than £10,000 per annum during the first five years of the Bureau's existence. It is proposed that the different Governments shall contribute on the following basis: United Kingdom, 25 per cent. of the annual expense; British India, 25 per cent.; Self-Governing Dominions, 25 per cent.; Crown Colonies and Protectorates, 25 per cent.

The delegates recommend that the next Conference be held in the year 1923, and that, if the Dominion Government approves, it be convened in Canada.

GENERAL NOTES.

Industrial Activity in Bengal.—Referring to the formation of so many new companies in Calcutta, the result of huge war and post-war profits on manufactured jute, hides, iron and steel, cotton yarn, piece-goods, paper, building materials, etc., the Calcutta correspondent of the *Morning Post* mentions that the local Stock Exchange list of miscellaneous industrial undertakings has expanded from some 30 to about 200. At the same time a large amount of new capital has gone back into the older jute and cotton enterprises. An interesting factor has been the appearance in Calcutta of certain leading English firms "driven to seek not merely new markets but new manufacturing centres for their processes by the higher costs of production at home." One London firm are in the field in the hope of exploiting India's pulp resources. Another contemplate the erection of a jam and pickle factory near Calcutta. He thinks that for the most part this industrial activity is perfectly sound. He adds:—"The resources of India, and more especially of the area which constituted the old province of Bengal, are limitless. On the west and south-west of Calcutta iron and coal exist in the same contiguity as in Lancashire, and numerous other minerals are already being exploited in that region on commercial lines. An official high in the Geological Survey assures me that, given capital, the development of the district of Singhbhum in the next thirty years should rival that of Pennsylvania or Westphalia during their great period of industrial expansion."

Industrial Research.—The British Leather Manufacturers' Research Association having been approved by the Department of Scientific and Industrial Research, as complying with the conditions laid down in the Government scheme for the encouragement of industrial research, has been granted a licence by the Board of Trade.

Eyestrain in Cinemas.—An interim report of the representative joint committee appointed by the Illuminating Engineering Society to inquire into eyestrain in cinemas forms part of the contents of a "special cinema issue" of the *Illuminating Engineer* (32, Victoria Street, S.W. 1). The inquiry originated in a request made to the Illuminating Engineering Society by the London County Council for information in regard to the possible causes of eyestrain in cinemas, and the best mode of removing them. Attention was particularly drawn to "the question of the strain to the eyes caused by the proximity of seats to the screen at cinematograph halls, and of some means of lessening the ill-effects referred to." The Committee received the co-operation of the Council of British Opthalmologists and the Physiological Society in dealing with this difficult problem, and seem to have taken great pains to make their investigation as complete as possible. They recommend (1) That the angle of elevation, subtended at the eye of any person seated in the front row, by the length of the vertical line dropped from the centre of the top edge of the picture to the horizontal plane passing through the observer's eye, shall not exceed 35°, the height of the eye above the floor-level being assumed to be 3 ft. 6 in.; (2) That provided recommendation No. 1 is complied with, the angle between the vertical plane containing the upper edge of the picture, and the vertical plane containing the observer's eye, and the remote end of the upper edge of the picture should not be less than 25°. They do not anticipate that any supplementary report which they may make will necessitate modification of the above recommendations. The representatives of the cinema industry, while approving of recommendation No. 1, draw attention to the absence of definite evidence of serious injury by eyestrain. In view of this fact, they are of the opinion that where application of this condition to existing halls would entail serious financial hardship there is no justification for its imposition. They are further of opinion that the normal development of the cinema theatre will rapidly remove all causes of possible discomfort.

NOTICE.

EXAMINATIONS.

The results of all stages of the examinations held from May 10th to 19th have now been sent to the centres concerned.

In the Advanced Stage 5,420 papers were worked. Of these 861 were awarded first-class certificates, 2,774 second-class certificates, and 1,785 failed.

In the Intermediate Stage the number of papers worked was 13,588, with 2,286 first-class certificates, 6,850 second-class, and 4,452 failures.

In the Elementary Stage 14,136 papers were worked. The passes numbered 9,787, and the failures 4,349.

The total number of papers worked in the March and May examinations this year is 49,390, against 31,132 in 1919. Of the former 7,062 were in the Advanced Stage, 1,098 first-class and 3,430 second-class certificates being awarded. The number of failures was 2,534.

In the Intermediate Stage 18,696 papers were worked. The first-class certificates numbered 2,964, the second-class 9,499, and the failures 6,233.

In the Elementary Stage the number of papers worked was 23,632. Of these 15,890 passed, and 7,742 failed.

In 1921 the first, or Easter, examination will commence on Monday, March 14th, and finish on Wednesday, March 23rd. The second, or Whitsuntide, examination will begin on Monday, May 2nd, and end on Wednesday, May 11th. The syllabus for 1921 will be published shortly.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE ARCHITECTURE AND DECORATION OF ROBERT ADAM AND SIR JOHN SOANE, R.A. (1758–1837).

By ARTHUR T. BOLTON, F.S.A., F.R.I.B.A.,
Curator of Sir John Soane's Museum.

Lecture III.—Delivered May 17th, 1920.

If architecture is to be seriously regarded as a reflection and record of the life in all its varied aspects of any particular period, then we must expect to find that Sir John Soane, however great an admirer he may have been of the architectural genius of his own early days in London, would yet, in his own subsequent work, achieve an artistic effect very different in character to that realised with such success by Robert Adam.

Much had happened since the climax of the late Georgian prosperity and magnificence, coincident with the mid-point of Robert Adam's career as a practising architect in London, a date which may be taken as almost that of Soane's first great success, the winning of the gold medal of the Royal Academy in 1776.

The disastrous American War, the domestic troubles of the Gordon Riots, the collapse of the King's system of personal Government through Lord North's Ministry (1770–1782), were only premonitory symptoms of the great avalanche of the Revolutionary Wars (1793–1815) which overwhelmed the existing social order in Central Europe, and profoundly modified that of our own country.

Robert Adam's own work, in his last years, when under Pitt's guidance the country appeared to be recovering its prosperity, seems to have assumed a graver cast.

By a curious inversion a greater parade of architecture is demanded on the exterior of the houses, a more distinctive assertion of the class rather than of the individual, and the interiors tend to lose their former importance. A more equal standard of decoration, a type in fact is being established for a majority, to which each individual will more or less be driven to conform.

Unlike Robert Adam, who was never recognised, young Soane was a chosen pupil of the Royal Academy. Sir William Chambers, founder and protector of the infant institution, had approved of his Triumphal Bridge, and had himself introduced the successful student to the Royal Patron, as a preliminary to his start upon his grand tour.

Chambers was incapable of change. In his last edition (1791) of the "Civil Architecture" of 1759 he reiterates his earlier condemnation

of Greek architecture. The work of Adam and Stuart was unchaste, subversive of true principles, and students and the public must be protected, on principle, from its pernicious influence. This frame of mind is a recurrent phenomenon, and there is no particular way of dealing with it, other than that of maintaining a sound tradition of artistic liberty and equality, if not of fraternity.

It is to Soane's credit that his individuality was strong enough to withstand this pressure. As a pupil of George Dance, R.A., he had been in touch with a gifted designer, whose trend was towards experimental essays, and new combinations. Unfortunately, Dance was weak on the constructive side, as well as somewhat lacking in energy. He seems to have admired the force and determination of his pupil. "Remember," he writes to Soane, "your motto *Mihi turpe relinqui*," while at another time he cautioned him to "sprinkle cool patience upon the heat of thy distemper."

Henry Holland, jun., to whom Soane appears to have been an assistant from 1772 to 1776 or 1777, was also an architect of rare ability, and a man of a modest and retiring nature. His earlier work is like that of Robert Adam and James Wyatt, but in the interiors of Carlton Palace he seems to have struck a note more definitely Græco-Roman, for which "Empire" is, perhaps, as nearly an equivalent term as any.

Soane's association in his Roman days with the Bishop of Derry, afterwards first Marquess of Bristol, seems to have brought him into touch with a learned society imbued with the classics. He makes designs for a "dining room" and a "canine residence" in the antique manner, but follows it up by modern versions of the same. This is very characteristic of Soane's practical habit of mind.

He studies the "antique," but as an artist who is in search of material for the development of his own powers and the realisation of his own ideals. A merely dilettante attitude was alien to his temperament. This is revealed in his attitude to a draughtsman, who showed him the usual sketches of the Pantheon portico at Rome. "Are the columns equally spaced," he inquires, and when the sketcher hesitates, a curt "Ah, I see you do not know!" closes the discussion. He himself had measured the Pantheon, and the bearing of the facts had not been lost upon him.

The effect of Soane's grand tour upon his mind appears to have been that of modifying his first love of Adam and Wyatt work, through the deep impression made upon him by the Greek Doric of Pæstum and Sicily. As is well known, he was prevented by circumstances from reaching Athens, and seeing the masterpieces of the Doric and Ionic styles in all their effectiveness. The Street of Tombs at Pompeii also, I fancy, profoundly impressed him.

The consequence was that when Soane began to rebuild the Bank in 1794, he treated its screen-wall decorative architecture on lines which were profoundly original. The new work was something entirely different from that which might have been predicted from a pupil of the designer of Newgate, and of a student who had come so directly under the influence of Chambers.

The interior of the Bank especially is remarkable because, although there is an apparent following of the scheme of the Roman thermæ, the character of the design is entirely novel. It is more modern than much that is projected or executed to-day. Soane's feeling for the bones of the architectural corpus is almost uncanny. The Bank interiors are as remarkable in that way as the much later work of Duc in the Palais de Justice at Paris.

When allowance has been made for the temper of Soane's age, as one of war with all its revulsions and ensuing exhaustion, his work holds good as an astonishing reversion to the bare realities of design, after the magnificence of Adam decoration and ornament.

Soane possessed a great feeling for surfaces, and his linear method of decoration perhaps arises from that source, as though he would abolish all projections, lest any shadows or excrescences might detract from their effectiveness. At the same time these considerations must not be pushed too far, as though Soane was wedded to a clearly-defined and closely-reasoned logic. He never was a clear thinker; on the contrary, he is given to flashes, often strangely phrased, which burst through an ultra dry form of verbal expression. Only when he is roused does Soane break through this acquired reserve, and even then there is a certain cloudiness, witnessed by phrases like the "poetry of architecture," to be achieved apparently by the union of forms and qualities usually regarded as antagonistic. It is easy to understand, therefore, that the attitude of his contemporaries was one of bewilderment, not unmixed with ridicule.

George Wightwick truly reports that no architect was ever less beholden to his own time, nor anyone more crudely assailed. It would have been too much to expect that the

essential quality of Soane's art should be generally appreciated in his own time. Even to-day it arouses questionings as to method after the general harmony of the whole has been admitted.

It is not pretended that Soane as an architect ranks with a master like Robert Adam. He is always a pioneer pointing towards something, which, perhaps, is incapable of being realised, and hampering himself by difficulties of expression never completely mastered.

For one thing Soane's design is extraordinarily fluid; he multiplies alternatives to an extent which produces absolute confusion, when the building, to which all these drawings, apparently finally, refer, is no longer in existence.

Worst of all Soane is apt to repeat forms already used by himself elsewhere, as though he had himself grown weary of his own vacillation.

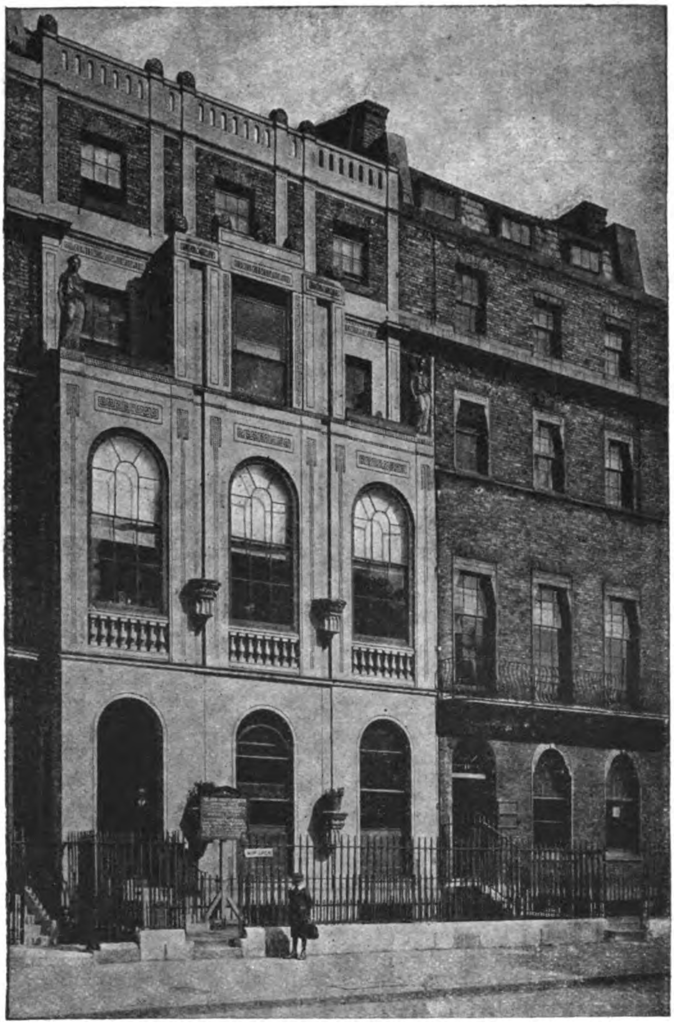
This uncertainty of temper probably accounts for the ridiculous importance that he attached to Père Laugier's architectural dogmas, as set forth in the "Essai sur Architecture" of 1755. This amateurish effort owed its passing importance to the circumstances of the time in France.

A tide of revolt had set in against the license of the Jesuit style, and the worthy Father, intent upon his intended reformation, propounded a short cut to purity by a drastic amputation of the body of architecture. There were to be no more pilasters, arcades, and high basements, no domes or other exuberances; all was to be reduced to the pure Order of Columns of the antique pattern.

There was, however, this anomaly, that in the desert was to bloom a new flower, a triangular church with three apses, at once mystical and correct. Soane seems to have taken all this quite seriously, and the implied dogmas were a fatal handicap to his monumental designs on several occasions.

An important incident, that can only be lightly touched upon here, was the check to Soane's artistic development, arising out of the fatal outbreak of the great wars in 1793.

Had his new House of Lords design, approved in 1794–6, proceeded, as in times of peace it certainly would have done, Soane would, by the test of the execution of his ideas on an adequate scale, have risen to a much higher rank as an architect, and gained a more effective influence on the art of his own, and probably of subsequent times. The problem of this design

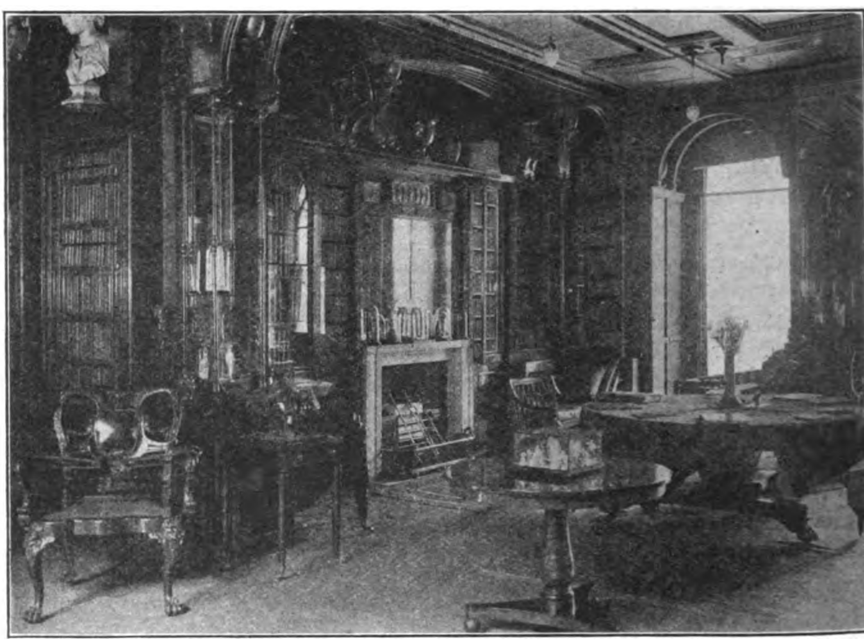


Sir John Soane's House and Museum, No. 13, Lincoln's Inn Fields.
Built in 1812. House on the right, 1824.
Similar house on left, 1792, Soane's first house in the Fields.

could only, with a man of his temperament, be solved by the clamorous exigencies of the actual work. He played with it for the remainder of his life, without ever being pinned down to a definite and convincing result.

The effect that a great range of state apartments in a national building, like the Houses of Parliament, would have produced in his hands can be judged in part only from the interiors of the Bank. Masterly as these are, they have always been too disjointed by business necessities, and too difficult of access, to have produced the culminating effect promised by the abandoned scheme.

the actual work executed by Soane in 1823 at the old Houses of Parliament, the famous Scala Regia, we have only the drawings and some contemporary report. It was day and night work, having been rushed through in seven months in order to gratify the impatience of George IV. That it was a fine design, we have the drawings of artists made at the time to show, and the only serious criticism seems to have been that it was, as usual, deficient in scale to realise the full effect. It is also possible that this interior was not so reticent in detail as the rest of Soane's work, but, when his buildings have disappeared, it is unsafe to express an opinion on this head,



Sir John Soane's House, No. 13, Lincoln's Inn Fields.
The Library on the Ground Floor Front.

Soane's buildings after the crisis of the war are manifestly crippled by a smallness of scale and means, inadequate for the real grandeur of the design. Dulwich Gallery and Mausoleum, for instance, do not, as built, possess the impressiveness of which Soane's design was capable.

Deprived of this quality, his architectural design is apt to be regarded as mean and ugly, by those who fail to appreciate the method of the artist, and to remember that "the best of this kind are but shadows, and the worst no worse, if imagination do but mend them."

It is against the critics that they could see this in Gandy's interpretations of Soanic design, and endeavoured to set the one against the other. Of

as experience of the effect of the Soane interiors made upon varying spectators will soon demonstrate.

The writer recalls his own impression of many years ago of the interior of the old Law Courts at Westminster, probably the first Soane work he ever saw. The earliest sight was bewildering; it was like something never seen before. It defied criticism in detail, possessing a harmony of its own which called for complete acceptance, or rejection, on the part of the spectator.

This fact naturally accounts for the hostility of opinion that followed Soane in his career, as closely as the great admiration of those who felt that he was undoubtedly possessed of genius.

It must be, therefore, worth while for the student to consider with some attention the theory and practice of an architect possessed of so much force of character.

One source of Soane's ideas seems to have been his own study of the antique mausoleums to which Robert Adam had called attention. In the endeavour to determine the true character of the private domestic architecture of the Greeks and Romans, as distinct from that of their temples, it was only natural that reliance should be placed upon those scanty remains of antique fresco decorations, that possessed backgrounds of an architectural character.

The argument may be stated as a proposition that painters do not in fact design, in the architectural sense, but simply recall what they have seen, and are familiar with, in the forms of the buildings around them.

Even Fergusson argues in favour of a metallic architecture in the ancient world. The bronzes of Pompeii and Herculaneum, moreover, show the design that was lavished upon candelabra and tripods, a care which may very well have been extended to those features of domestic interiors for which metal could be used. It is quite possible that woodwork was treated in a metallic sense, where bronze or iron could not be afforded.

It is certain that the design of the library of the Soane is derived from hints of this character, and that there is a deliberate attempt to realise the flying arches, and other features, hinted at, in the backgrounds of antique frescoes. In the miniature loggia of the first-floor front we have a much later attempt to realise some Roman gallery, as it might have existed in an imperial palace, or large villa. Colonnettes of metal are reproduced in wood, decorated as green bronze, in conjunction with busts resting on metal-like architraves. Candelabra, medallions and bas-reliefs are brought in as elements in the scheme. The extraordinary complexity of the remains of the Villa of Hadrian, at Tivoli, suffices to show how wide a range of domestic work must have existed in Antiquity. This particular example, moreover, was probably not considered, by the architects of the period, as much more than the extravagance of an imperial amateur. We have, therefore, little more than a hazy idea of the work of the great architects of the old world of Greece and Rome, in the domestic sphere. It is as though the Vatican had perished, and we had merely St. Peter's as a witness to the age of Bramante, Peruzzi, Pi·ro Ligorio and Raphael.

Sir John Soane's House, No. 13, Lincoln's Inn Fields.
The Breakfast Parlour.

The building of Pitzhanger Manor in 1800–2 affords a useful clue to the line of development of Soane's domestic interiors.

Previous to this work he may be said to have worked in an attenuated version of the Adam style. The interiors of No. 18, New Cavendish Street, which he fitted up for the Earl of Hardwicke, are a case in point. It is not certain that the fine-drawn ceiling on the front first-

floor drawing room is his, but it is very probable. Here we see work of a Wyatt-Adam character.

In contradistinction to Robert Adam, Soane was not a unique master in the special field of house-building. His work is always interesting and full of ideas, but there is an architectural *parti pris*, which hampers the full and free expression of its domestic character. It calls to mind a saying, which may perhaps be traced back to Norman Shaw, or Nesfield, that what the student requires is to eliminate *the architecture* from his house design.

Pitzhanger is interesting as an architect's house, a classical villa essay. Soane was thinking of a "house for an architect in the antique manner." Horace Walpole tells us that he suggested that "the Gallery of Syon should be fitted up in the manner of an antique columbarium," about the last idea that it excites in Robert Adam's hands. Soane's largest and most important house was Tyringham, in Bucks. There is a fine reserve about the exterior. It illustrates what he was intending for the new House of Lords, a design in hand at the same time.

The hall vestibule was practically one bay of one of the large halls of that design. The centre of the house was sacrificed to a lanterned structure, or "tribune," of the type which Soane realised more effectively in the Pitt Cenotaph, at the National Debt Redemption Office, in 1818. The architect was thoroughly pleased with the house, and George Dance both admired it and proposed to "steal from it." It certainly had dignity and character, but as an English home it left a great deal to be desired.

Unfortunately Soane did not build his design for Butterton, in Staffordshire (1816). This is an Adamitic-Greek design, rather suggestive of a medium sized museum or town hall. The interiors, following on his experience with his own house in Lincoln's Inn Fields (1812), would have been of great interest, as an illustration of the further development of his ideas of interior decoration. When Soane built for himself he had always his collections to house and exhibit, and, therefore, it is difficult to judge what he might have done, when free of such considerations.

Bank of England. Sir John Soane, R.A., Architect.
The first part built 1792–6. Eastern end of façade to Threadneedle Street.

The circumstances of the time must be recalled. Even the painter Lawrence filled his rooms with casts of statues and Greek architectural details. In 1830 Barry puts a cast of the Parthenon Frieze round one of the interiors of the Travellers' Club, and in the Reform (1837) there is a relic of the same idea in the smoking room. The younger architect was emancipating himself, and the interiors of the Reform Club as a whole marked a new departure.

Decimus Burton, in Grove House, makes his circular hall like the lantern of Demosthenes turned inside out. If this is recalled as an outline sketch of the ideas of the time, the merit of

Soane's interiors in his own house in Lincoln's Inn Fields will be better appreciated.

Pitzhanger illustrates in its interior how far Soane had lost touch with the Adam scheme of decoration, because, although he refers to the two rooms there by his master, Dance, which he was preserving, as "exquisite," he makes no attempt to follow the same style. Admittedly the main feature of the exterior recalls his admiration of the Adam centre-piece of the south front of Kedleston, but his own new interiors were purely Soanic.

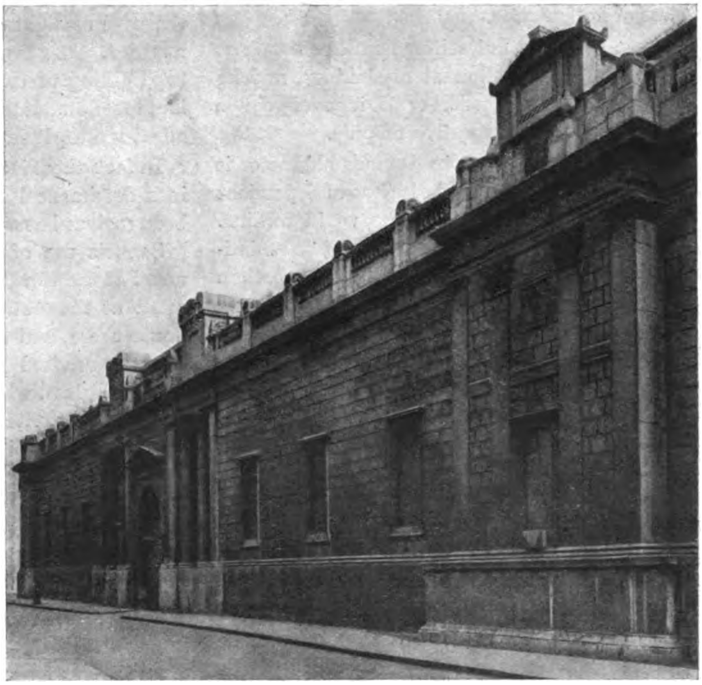
As compared with No. 13, Lincoln's Inn Fields, of ten years later, the Pitzhanger interiors retain too much of the mausoleum character.

The most symptomatic room is the front parlour, which contains the germ of the famous breakfast parlour of the Soane Museum. The differences, however, are remarkable. In the later work, apart from the structural novelty of the lighting, by which the earlier dome-vault becomes a canopy with two sides clear of the walls, the elimination of the caryatid element of the earlier design shows a much greater appreciation of domestic character.

The Pitzhanger parlour had a marble effect, while that of the Soane is suggestive of wood. Taken as a whole, the tendency of his design is in the direction of an omission of all projecting features. Everything becomes flush, and all the usual details of skirting, chair rail, architrave, and cornice are boldly dispensed with. Even the door panels are made flush, and inlays, or reed flutings, replace the customary sunk and moulded surfaces.

A little later Soane was attracted by the possibilities of mirror glass for the reduction of shadows, and the illumination of blank surfaces. I do not think that his idea was at all that, which later on became such an abuse, the endeavour to multiply interiors by the use of large sheets of the reflecting surface of mirror glass. Where a comparatively long piece of unbroken mirror is used, over the bookcases on the west wall of the library, a special effect was arrived at, that of giving clearance to the flying arches, and of repeating the horizontal plane of the ceiling with its compartments. It is a special case, which is justified by its surroundings and undeniable effectiveness. Soane makes a further use of spherical mirrors in order to focus certain interior views. These are decoratively distributed in panels forming part of the internal design.

Splayed jambs to windows, or archways, are also sometimes panelled with mirrors, with a view to the better distribution of the light. When Soane calls attention to the compartments of the ceiling of his house, he connects them in idea with the main lines of the floor construction above. This shows that he wished to avail himself of the depth provided by the old system of girder-beams, binders, and double floor and ceiling joists. Inside this framework he devises panels with spherical surfaces, an outcome of his exceptional knowledge of domical and vaulting problems.



Bank of England. Sir John Soane, R.A., Architect.
East Half of Back Elevation.

From a curious memoranda, preserved by one of his travelling companions, it would appear that such problems had been thoroughly explored in his early days.

The type of cross vault, that is seen at Pitzhanger and in the Soane Museum, is one that occurs in Southern Italy. It is a method of eliminating the groin by the use of a flat surface, forming, as it were, a gusset. There are thus two intersections instead of one. I believe that this system, which I have seen in process of building on the eastern coast of South Italy, arose to a large extent from the need of dispensing with centering, as the masons seem able to carry out these vaults on practically a self-supporting basis. Soane, at the Bank, had already displayed great ingenuity in constructing his segmental and other vaults, and domes, by means of hollow pots.

Where he uses a flat ceiling he often dispenses with all but the shallowest of sinkings, and he relies on lines of reeds, or strings of single beads, rather too suggestive of pills.

Another form of a more dubious character is the Soanic pendant, a kind of frieze of dependent drops, like reversed cones, concave in outline. Probably this arose out of an attempt to assimilate features of a Tudor and Elizabethan character.

If justification for these divergencies is needed, it may be found in the proposition that constructional features in architecture tend to pass into forms of decoration, and that the use of such features is governed only by the artistic instinct of the architect.

The attempt to apply the logic of ethics has always involved contradictions of theory and practice, visible enough to all but the convinced partisan. Whatever the theory that may be put forth as an infallible guide in architecture and decoration, it is surely obvious that it must be applicable to all styles alike, and be true of the most ancient, as well as the most modern masterpieces.

When Soane deals with colour in internal decoration he proceeds on lines quite opposed to those of Robert Adam. In the interiors of his own house he depends on the natural colours of the wood and marble, either actual or in paint, with the relief derived from metals, and metallic colours, like bronze. He then obtains emphasis by masses or bands of bright positive colours, *i.e.*, bright Venetian, or Pompeiian, reds, and yellows, primrose, or golden, in hue.

Although Soane uses polished brass, in connection with woodwork of mahogany inlaid with ebony, as in cappings and inserted colonnettes, he does not seem to have indulged in gilding, which is remarkable, when we remember the common form of the white and gold interiors of his own period.

In the course of time the original colours of the drawing rooms and the staircase at the Soane have been lost sight of, and green has been introduced with an effect quite un-Soanic.

Probably the interior of the museum itself was in stone colour, because here Soane was relying on the vivid hues of the stained glass in his lanterns. Red, purple, blue, and varying shades of yellow, were employed with a double motive, firstly, to modify the light, in which the marbles and casts were seen, and, secondly, to obtain flashes and local spots of vivid colour, through the rays of light passing through his coloured margins. The large use that Soane makes of top lighting, preferably through lanterns, enabled him to follow out these ideas, because the powerful effect of a top light removed any fear of obscurity.

In fact, there is now an excess of light, resulting in a detrimental glare, where his lanterns have been reglazed at any later time with clear glass.

Soane's use of coloured glass was certainly novel at the time, because gibes were frequently made at the "stained glass dome" in his own house there, and at the new Law Courts (1824). He was advised by his friends to take out the coloured glass, which he had put in, in view of the ridicule excited by its novelty.

In Soane's bands of brightly coloured glass, roundels or guilloches, etc., were etched out in white, probably by an acid, and then shaded, with a scratched high light. Unaltered houses of his period, and up to say 1840, will often be found with these margins of coloured glass, before the general revival of leaded glass. There is one important distinction in Soane's use of yellow glass to diffuse an effect of sunlight, which arises from the fact that some of the glass is white, while the colours have a considerable range in tints from light to dark. I do not think this was merely an inequality of manufacture in the glass, but that it was deliberate on his part, and the resulting effect is quite different to that produced by a needless uniformity of tone, as may be seen in the mausoleum at Dulwich, which must surely have been reglazed at some later time.

It would not appear that in respect of the painter's art, Soane drew any marked distinction between easel pictures, and paintings deliberately decorative. The "History" School of the period, that of West, Northcote, Hilton and Haydon, was regarded at the time as a British achievement, which it was a patriotic duty to patronise and support. If Soane's earnest desire, to have placed two paintings of this character

in large panels on the walls of his Scala Regia had been fulfilled, it is to be feared that the decorative result would have been small, while as pictures they would have been no better than the canvases of Durno, Howard, and Jones now in the Soane.

It is probable that Soane, during his time in Rome and Italy, was too exclusively devoted to an absorbing study of architecture, and architectural design, to be able at a later period of his life to free himself from the current ideas of his own day. Although a personal friend of Turner, his choice of the three works by that master, now in the museum, shows no instinctive grasp of the real tendency of that great painter's revolution in art. It is also remarkable that Gainsborough, David Cox, and Constable are not represented at all in the Soane.

In the ceiling of the Soane library and dining room, the paintings by Henry Howard, R.A., inserted as late as 1834, are decoratively less effective than the purely architectural panels, and the ceilings of the two drawing rooms above would gain little by painting. The earlier ceiling of 1792, at No. 12, had a trellis-painted decoration, but Soane did not repeat the experiment.

The Privy Council Chamber ceiling (1824) shows no hint of any such decoration.

It might even be argued that Soane in his pictorial decorative essays was merely acting under the impression produced by Haydon's active campaign, which eventually led up to the Westminster Cartoon Competition, and its not very fortunate outcome, the frescoes of the new Houses of Parliament.

There were considerable limitations in Soane's theoretical endeavour to unite sculpture with architecture. In the most typical Soanic work sculpture plays a very minor part, if not entirely absent. One or two rather wild designs on paper show an excess of caryatid figures, that would have been better entirely omitted. At his best, when he was employing Banks, the sculpture provided at the Bank is only a pair of roundels, of the type used in the Roman triumphal arches, and some suggested figures on the skyline, as in Palladio.

Some cherubs in pendentives, or in the dies of pedestals, are similarly limited examples of its use. He had a passing idea of inserting a series of bust-like heads, between the trusses of the large Italian cornice of the State Paper Office, but was fortunately persuaded to omit them.

Bank of England. Sir John Soane, R.A., Architect.
Angle to Lothbury and Princes Street. (1805–8.)

As good an instance, as any, of Soane's use of sculpture were the caryatid figures on the staircase of the Marquess of Buckingham's house, in Pall Mall, (now pulled down).

At the same time Soane most certainly appreciated Flaxman, and secured some of his best models. He also collected Wedgwoods by Tassie and Webber. Thanks to him also we have the four fine eagle panels from Carlton Palace, the work of his former chief, Henry Holland, junr. It might very plausibly be argued that Soane's most interesting and characteristic

work is purely architectural, and dispenses with both painting and sculpture, for instance, the Tivoli Corner of the Bank, the Loggia of the Governor's Court, the Vestibule Entrance from Prince's Street, and the façade of his own house. In the last instance the two isolated figures are not essentials of the design.

Soane's attitude to the decorative arts was inconsistent. He actually apologises for Robert Adam's attention to decorative details, on the ground that William Kent had done the same! This false attitude may be regarded as an outcome of Reynolds's "high art" doctrines, and the absurd isolation of "History" painting as a supreme emanation of art. It is allied to Chantrey's later neglect of detail, as of something opposed to the purity and grandeur of classic sculpture, etc. The fact is, of course, that very erroneous views prevailed as to the practice and theory of the Greeks. Even Flaxman in his lectures displays a curiously limited appreciation of the art of the Early Renaissance period, and an absolute indifference to its later developments.

The touch that Robert Adam alone had established with these schools disappeared in the course of the Greek Revival. Not until the appearance of Alfred Stevens did the decorative aspect of sculpture, in relation to architecture, obtain a fresh recognition in England.

The unique aspect of Soane's work, its peculiar harmony in itself, and freedom from vulgarity, can best be appreciated perhaps by a comparison with such contemporary work as the long gallery at York House (now the London Museum), and at Apsley House, the Waterloo Gallery, all interiors by James Wyatt's sons. The Buckingham Palace interiors, also, the work of John Nash (1827), illustrate the poverty-stricken condition of the contemporary design of interiors, and the steep descent from the high level of the Adam period.

Some interior work by Decimus Burton is alone comparable with Soane's, until we come to the work of Barry and Cockerell. In the case of the latter his early work at the Bank compares unfavourably with that of Soane. C. H. Tatham writes in 1833 to Soane of some early work, probably at the Bank, by young Cockerell, as to the identification of which I am uncertain:—"Exteriore cattivo! Interiore peggio!"

The interior of the Hanover Chapel in Regent Street (now pulled down) was much below the exterior in refinement and effectiveness.

The old Debtors' Court in Portugal Street was a good instance of Soane's power of producing a fine interior out of very simple constructive elements. From the drawings and photographs, which are all that remain, it is clear that this square interior, with four large semi-circular arches, carrying a flat ceiling, possessed a great deal of character. There was also a kitchen under the state room added to Freemasons' Hall, which appears to have had a similar effectiveness. It might have been anticipated that the National Church Building Movement of 1818 would have produced something of the effect of the earlier essay, in the reigns of Queen Anne and George I.

Soane, who was consulted in the company of Nash and Smirke, did his best to secure adequate results, but his Report, urging an allowance of £30,000 for the larger churches, was fatally disregarded for an absolute limit of £20,000. Soane's best design for Marylebone was consequently shut out, and from the two or three examples, which he did carry out, it is only too evident that he had lost any vital interest in the matter.

The rejected design, preserved in a good model, is one of very great interest. It is an arcuated structure with a continuous vault having openings that serve the purpose of a clerestory. The tall moulded round arches and piers have no imposts, and the subordinate gallery is well contrived, without any break in the main lines of the interior. A bold segment arch of the full width of the church marks off the chancel. The whole structure has more sympathy with the early Romanesque, than with any phase of the succeeding Gothic. It was an experimental design that deserved to be executed, and might have proved fruitful. Certainly it was far in advance of the generality of the churches built out of the million grant.

In conclusion, it may be pointed out that this brief survey, in touching on the Architecture and Decoration of Robert Adam and John Soane, has extended over three-quarters of a century.

At the outset Palladianism was in the ascendant, challenged only by French and Chinese tendencies, as well as by the opening buds of the coming Gothic, and Greek, Revivals. At the close of the period all that was left of Palladian tradition was in process of being transformed by the Astylar Italian, introduced by Sir Charles Barry, who was breaking away from his early adherence to Grecian Revivalism.

Mediævalism had grown into a formidable movement, and the generation immediately following upon Soane's death in 1837, was to witness both the high-water mark and the ebb of that movement.

The veteran of eighty-four was perhaps the last of those who could put in any claim to the friendship of Robert Adam, and with a prophetic instinct he had secured the great possession of the remaining original drawings of the master, at a time when Robert Adam's work and reputation were under a deep, if passing, cloud.

As Sir John Soane's pupils died off appreciation of what he had achieved declined. His great collections were valued for other things than those upon which his own heart had been set. His house came to be regarded as the expression of an eccentric, a monument of personal vanity, and his work as anything but a serious contribution to architectural thought.

The destruction of Soane's buildings has been very extensive, and it is fortunate that his tree was too deeply planted to be entirely rooted up.

It is singular that one of the most discerning tributes to his work should have come from George Wightwick, temporarily in his employ as a private secretary, who left him in a rage after some three months' service in 1824. This personal contact, however, mellowed by the experience of professional life on his own account, and by the passage of time, left a deep impression on the younger man, which is finely expressed in his "Palace of Architecture."

Probably few to-day would care to assail the position of Robert Adam, as a revolutionary artist whose work has left a permanent trace in the history of Architecture.

Sir John Soane's contribution to architectural thought may be challenged, and only the future can show the quality of the wheat as distinct from the tares, which are so easily detected and dwelt upon. That there is a continuous thread running through the whole of architectural history seems self-evident. Each generation essays its own problems in a different spirit, but the tradition is always present, and the task of assigning relative values to the individual contributors is not one to be lightly essayed.

It is sufficient to claim for Soane the possession of original ideas and a power of expression, which makes his buildings so distinctively his own.

Invited to address you here in a House, erected for your Society by Robert and James Adam in 1772–4, I have had the privilege of speaking before a Society, which was nominated by Sir John Soane himself as an elector of a Representative Trustee of the Sir John Soane Museum, being myself its Curator.

It only remains for me to thank you most sincerely for the privilege, and to express my sense of the kindness of the attention which has been given to my subject.

Epilogue.

On the occasion of the third Lecture, in view of certain rumours in the Press, the foregoing was not delivered as printed, as it was thought that the minds of the audience would be occupied with the Bank. Occasion was, therefore, taken to point out the value and importance in the history of English Architecture of Sir John Soane's masterpiece. As, however, an account, fully illustrated, will, it is hoped, shortly be given of this and others of his buildings, in a separate "Publication of the Sir John Soane Museum," it would be superfluous to print here what was actually said on the occasion of the third Lecture. Three special photographs which were taken to make slides for this lecture are, however, reproduced. The first of these shows the earliest part (1794–6) of Soane's rebuilding of the Bank, this right-hand wing being subsequently repeated in 1823, when the left-hand wing of the Bank was rebuilt, as the later portion of the work. The centre block, not shown, is a recasing of the original Bank building, of which Sampson was the architect. The second illustration shows the first half of the North, or back façade, of the Bank. As, owing to the street improvements of 1800, it became necessary to double this frontage, Soane desired to build a great hexastyle portico, as the centre feature of this newly-extended façade. The necessary projection into the street being, however, refused, Soane was obliged to content himself with the narrow-bay design, seen on the right-hand side of the photograph, which as a centre he always felt was inadequate. The third photograph shows the masterly angle feature of the north-west corner of the Bank at the junction of the two streets. This unaltered work gives the full effect of Soane's unique design, and it has always been regarded as his masterpiece. The design is given in relief on the reverse side of the gold medal presented to him in 1834 by the architects of England.

[The six illustrations of Sir John Soane's work are from blocks kindly lent by the Trustees of Sir John Soane's Museum. Copyright reserved.]

MEDICINAL PLANTS IN BAHIA.

The State of Bahia (Brazil) offers to the medical world an abundant and varied supply of plants, roots, barks, and gums, including many of recognised value, and some regular articles of export such as ipecacuanha root, araroba powder, jaborandi eaves, and Jatobi gum. Most of the plants exist in practically inexhaustible quantities, but orders

must be placed in advance with local exporters, for there is no regular trade even in those articles now appearing among the State's exports. The supply depends entirely upon the demand. The following list of the most important medicinal plants found at convenient distances from the city of Bahia has been furnished by the United States Consul there :—

Angelica (*Gentiana rubra*).—Aromatic, antiseptic, and anti-spasmodic; a remedy against intermittent fevers.

Arco leaves.—A substitute for the coca leaves of Peru; a stimulating and strong tonic, yielding cocaine.

Araroba or Goa powder.—This is a powder taken from the heart wood of a tree known locally as "amargoso do matto" (Vouacapoua araroba), which contains a substance known as chrysarobin, used in the treatment of skin diseases.

Barbatimão bark.—The inner bark contains phosphate of lime, tannin, and an alkaloid similar to quinine; it is a sedative, and reduced to powder makes an excellent dentifrice.

Cajueiro (*Anacardium occidentale*).—The bark is astringent and is an efficacious remedy against diabetes.

Caroba leaves.—Anti-syphilitic and anti-bubonic; well-known in Brazil as a powerful blood cleanser, used externally and internally. It is a vegetable mercury and is said to be superior to sarsaparilla and other blood purifiers.

Cambará leaves.—A strong sedative and expectorant, for bronchitis, coughs, and pulmonary ailments.

Cameleão da costa.—A remedy for stomach trouble.

Cestrum leaves.—A strong narcotic, said to be poisonous; also used in baths against hæmorrhoids; a powerful insecticide. The damp leaves are applied to wounds, first inflaming them, but afterwards cleansing and healing them.

Congonha.—A stimulant, diuretic as a tea.

Gervão.—Aids digestion, and eases laborious births.

Imbauba.—Remedy against coughs, bronchitis, and asthma.

Imburana.—Inner bark contains coumarin; it is aromatic, an expectorant and a stimulant.

Ipecacuanha.—This is a shrub growing in the shade of the forest, the root of which is dried and powdered for use in medicine. It is valued as an expectorant, diaphoretic, and emetic. It is not cultivated, but care is taken in digging up the plants to leave sufficient roots in the soil for another crop.

Jaborandi leaves.—Aphrodisiac, sudorific, and stimulating. From these leaves is extracted pilocarpine, which is used in tonic preparations for the hair.

Jurubeba (*Solanum paniculatum*).—Remedy for congestion and maladies of the liver.

Loco leaf.—A vegetable caustic.

Carnauba wax.—A tasteless, aseptic wax extracted from the leaf of a palm-tree known locally as the "carnaubéira," and employed in the preparation of ointments, pomades, and pills.

Mamona.—This is Portuguese for the castor plant, which was introduced into Brazil from India and China by the earlier colonists, but spread so quickly as to have the appearance to-day of a forest plant. Both the seed and oil are exported from Bahia in increasing quantities each year.

Manaca root.—Anti-syphilitic vegetable mercury.

Jatobá gum.—Jatobá is a name applied to several species of trees found in the valley of the River São Francisco, which traverses the northern and western parts of the State of Bahia. The gum which is extracted from this tree is employed in the composition of syrups for pulmonary affections. It is variously known locally as jatobá, jatahy, and jutahy.

Jatobá bark.—The bark of the above-mentioned tree is also of value in the preparation of medicines, and is employed as an astringent and carminative.

Mango tree (*mangifera indica*).—The leaves are anti-asthmatic.

Mentrasto.—A plant, stimulating against colics and used in fevers; also in baths, to cure weakness.

Milhomens (*Aristolochia cymbifera*).—Used against paralysis, dropsy and stomach trouble.

Mulungu (*Erythrina mulungu*).—The inner bark is a powerful sedative, narcotic, and anti-spasmodic, and is a substitute for belladonna; it also exercises a special action on the liver.

Pareira brava root (*Cissampellos pareira*).—A strong tonic, remedy for stomach trouble, bladder trouble, beri-beri, brain fever, and meningitis.

Pao ferro.—A bark used against diabetes; the seeds furnish a strong tonic and diuretic.

Purga de campo.—Remedy for fevers, pleurisy, tumours, and cancerous wounds.

Pindahiba.—Remedy for stomach trouble and for intestinal flatulence.

Quina-quina.—A bark used against fevers.

Quitoco.—Carminative, anti-hysteric, and digestive; used in baths for muscular pains in the body.

Samambaia.—Used for rheumatism.

Velame de campo.—Blood cleanser, anti-syphilitic and anti-rheumatic, for skin diseases and swelling of the glands.

INDIAN HIDES AND SKINS.

In 1916 the Secretary of State for India authorised the Committee for India of the Imperial Institute, of which Sir Charles McLeod is Chairman, to conduct an inquiry into the possibilities of increasing the trade in Indian raw materials with the United Kingdom and elsewhere in the Empire. Special committees, including commercial experts, were formed to deal with various materials. The reports of these committees, which contain important information and recommendations regarding the extension of the industrial utilisation of Indian raw materials, are in course of publication as a series of volumes by Mr. John Murray.

The first volume, relating to Indian hides and skins, which has been issued, contains the

reports of the Hides and Tanning Materials Committee on cowhides (kips), buffalo hides, and goat and sheep skins, and also a detailed account of the trade in Indian hides and skins. The most important of these products are kips and goat skins. Before the war the value of the annual exports of kips from India was about £4,000,000, whilst goat skins to the value of over £2,000,000 were annually exported, and in addition over £1,000,000 worth of tanned goat skins. The annual values of the buffalo hides and sheep skins exported from India before the war were about £1,500,000 and £900,000 respectively.

At one time a large proportion of the exports of raw Indian kips was tanned in this country, but subsequently both the tanning of the hides and the export trade from Calcutta gradually passed into German hands. In 1913-14, the value of the kips exported to Germany amounted to £2,000,000, and to Austria £750,000, whilst those shipped to this country had a value of only £63,000. The Report deals with the measures necessary to recover this important trade and to keep it in British hands, and recommendations are made as to the necessary conditions for re-establishing the tanning of Indian kips on a large scale in this country. One of the principal recommendations was the imposition in India of an export duty on the kips, with a rebate to tanners within the British Empire, and this measure has since been adopted by the Government of India and is now in force. The Committee also favour increased tannage in India.

Most of the goat skins exported from India are shipped to the United States, where they are tanned by the chrome process for the production of glacé kid, which is largely sent to this country. It is believed that a great extension of chrome tanning here and throughout the Empire is possible, as large quantities of raw goat skins are available in India and other British Possessions. The fact that a preferential export duty on raw goat skins, similar to that on kips, has now been imposed by the Government of India should contribute to this end.

Before the war, goat skins tanned in India were largely shipped to London for disposal, but the leather was mostly utilised in foreign countries for the manufacture of fancy articles, which in turn came back to this country.

NOTES ON BOOKS.

INDUSTRIAL CONTROL. By F. M. Lawson, Assoc.M.Inst.C.E., A.M.I.Mech.E. London: Sir Isaac Pitman & Sons, Ltd.

This book contains many original and novel ideas. It is based on a course of lectures delivered before the University of Sheffield, in which Mr. Lawson described a system he has devised for what may perhaps be not unfairly termed industrial or factory book-keeping. He himself calls it a system of "exposed records," and its main principle consists of the substitution of diagrams and charts for the ordinary books of account, or perhaps the addition of such diagrammatic methods to the ordinary system of book-keeping. A main feature of the system is that the "records" are open to general inspection, and it remains to be seen how this feature will commend itself to manufacturers, who are at present certainly not inclined to encourage publicity of their methods.

To describe the scheme in any detail within the space available for a brief notice would be impossible. For this reference must be made to the book itself. It must suffice to say that it is most ingenious and thoroughly scientific. A moderate number of charts and "exposed record boards," all available for immediate and simultaneous inspection, appear to be capable of giving a diagrammatic record of the actual condition and working state of a factory, showing at once the stock in hand of material, the state of progress of the different jobs in hand, and the available amount of finished goods, articles, machines, etc., ready for sale or delivery. The author gives details of the charts, etc., required for several actual factories. One is a file works in which only a single article is made, but in a great variety of different sorts, and from a limited variety of material; another is a manufactory of safes, in which the assemblage of a large number of parts is required, after the parts have been completed. In both these specified cases, it is fair to say that Mr. Lawson gives the names of the firms to whose works his system has been applied, and they speak in highly favourable terms of its value.

Only an expert in factory organisation would be justified in expressing an opinion on the practical value of the new system, or could say whether existing methods are as deficient as Mr. Lawson certainly thinks. In theory, however, the new ideas seem to be feasible, and to possess certain obvious advantages. If a general *conspectus* can thus be provided of all that is going on in the different departments of a factory, the work of the manager or superintendent must be greatly facilitated. He can see at once which departments are behindhand, and perhaps keeping back some particular order (or it may be a whole series of orders), for the want of some special part. He can tell when the stock of some particular material or some particular part is getting low, and generally can facilitate the uniform and steady progress of all the work in hand.

The introduction of scientific and ordered method, in place of the ancient "rule of thumb," cannot fail to be beneficial. For this reason it may well be worth while for the directors, managers, and proprietors of many manufacturing concerns, however well satisfied they may be with their own methods, to consider whether those methods may not be capable of improvement by the introduction of some of Mr. Lawson's novel and ingenious ideas.

GENERAL NOTES.

Destructive Insects.—A leaflet (No. 22) of the Ministry of Agriculture, deals with the diamond-back moth, and describes methods of control. Diamond-back caterpillars infest turnips, swedes, cabbages, kale, and other plants of the group *Brassica*, and sometimes cause considerable injury. Ichneumon flies (*Limneria gracilis*, Gravenhorst) attack this moth, and although they do not increase sufficiently in the case of an epidemic, they save the country from an annual recurrence of the pest. Diamond-back caterpillars are also devoured in large numbers by starlings and other birds.

Rare Metals in Ontario.—In addition to being the premier mining province of Canada as regards gold and silver, Ontario produces other rare metals that are even more valuable than gold. During the past year platinum and palladium were recovered at Port Colborne, and also by the International Nickel Company at its Bayonne refinery. At the latter, according to *Production and Export*, 19,528 tons of Bessemer matts were treated during the year, from which platinum, palladium, rhodium, osmium, iridium, and rutheorium were recovered. In all, 2,770 fine ounces were obtained, the estimated value being $200,000. Quotations on the rarer metals are difficult to obtain. The average price of platinum for the year was $114 per fine ounce. Palladium has been valued at $150. Iridium is now quoted nominally at $300 per ounce troy. The average value of iridium imported into the United States in 1918 was $114, and for osmium it was $58 per ounce in 1917.

Afforestation in the United Kingdom.—*Nature* reports that landowners have shown considerable sympathy with the objects of the Forestry Commission, and in several cases free gifts of land or long leases on specially favourable terms have been obtained. The area of land acquired in the United Kingdom is as follows:—England, 9,177 acres; Wales, 6,329; Scotland, 23,472; and Ireland, 4,716. This is exclusive of land acquired by the Irish Agricultural Department and administered by the Commission. Negotiations are in progress in respect of 24,973 acres in England, 7,900 in Wales, 6,956 in Scotland, and 7,000 in Ireland; and land on other estates is under consideration. The area planted during 1919-20 was 1,585 acres, most of which is showing satisfactory progress. A school for the forestry training of disabled ex-Service men is about to be opened in the New Forest. A similar school is already in existence at Birnam, near Dunkeld.

Hydro-Electric Works in Ceylon.—According to *The Times Trade Supplement*, investigation of the hydro-electric resources of Ceylon, which was interrupted by the war, has been again taken up by the Public Works Department of the colony. "Arrangements are being made for an early beginning in the partial conversion of the railway from steam to electricity, and also in connection with the proposed electrification of the island's industries. The experience of Ontario and Tasmania suggests that the utilisation of Ceylon's water-power resources for generating electricity will mark the beginning of an era of great industrial expansion in the Pearl of the Orient. A good supply of labour is at hand, and the opinion is held in some quarters that Ceylon is destined to become one of the great manufacturing centres of Asia."

Textile Institute Congress.—The Autumn Congress of the Textile Institute, whose head-quarters are in Manchester, is being held this year in London at the house of the Royal Society of Arts. At the opening meeting on Thursday evening, September 30th, Professor H. Maxwell-Lefroy, F.R.S., of the Imperial College of Science and Technology, will deliver the Mather Lecture, his subject being "Insects as Controlling Factors in the Supply of Cotton and Textile Materials." On Friday morning, October 1st, the President of the Institute (Sir Herbert Dixon, Bt.) will address the Congress, after which Mr. Oscar S. H. Hall, M.I.M.E., of Bury, will submit a paper on "Woven Fabrics: Achievements and Possibilities." On the same day members of the Institute will be entertained by the Clothworkers' Company at their hall, and afterwards visit the Exhibition of the British Institute of Industrial Art. On Saturday, October 2nd, a visit will be paid to the National Physical Laboratory. In 1917 the then President, the Right Hon. Sir William Mather, started a Foundation Fund for the development of the Institute, and on his retirement, in 1918, contributed a further sum of £1,000. Under his successor, Sir Frank Warner, K.B.E., the fund has risen to upwards of £11,000, and it is anticipated that in due course the amount aimed at, £50,000, will be realised. A gift of £2,000 from Mr. John Crompton, of Manchester, in memory of his son, who fell in the war, has been devoted to providing prizes annually for design and structure of woven fabrics, the competitors being advanced students at technical institutions.

"The Coal Fire."—A report entitled "The Coal Fire," which describes the work carried out by Dr. Margaret Fishenden in connection with research into domestic heating, and the efficiency of open fires, has been published for the Department of Scientific and Industrial Research by H.M. Stationery Office (price 4*s*.). This investigation, which was directed by the Air Pollution Advisory Board of the Manchester City Council and given grants-in-aid by the Research Department, has yielded a collection of carefully ascertained data from which, it is believed, a new departure can be made in dealing with the whole question of the use of coke and other forms of smokeless solid fuel in domestic fires.

Journal of the Royal Society of Arts.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

SPECIAL MEETING.

On FRIDAY, OCTOBER 15th, MR. THOMAS M. AINSCOUGH, O.B.E., His Majesty's Senior Trade Commissioner in India and Ceylon, will read a paper on "British Trade with India."

The chair will be taken at 4.30 p.m. by SIR CHARLES C. McLEOD.

INDIAN SECTION COMMITTEE.

The following is the list of the Indian Section Committee, as appointed by the Council:—

Alan A. Campbell Swinton, F.R.S. (Chairman of the Council).
Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I. (Chairman of the Committee).
Lord Ampthill, G.C.S.I., G.C.I.E.
Sir Charles H. Armstrong.
Sir Arundel T. Arundel, K.C.S.I.
Sir J. Athelstane Baines, C.S.I.
Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Sir Charles H. Bedford, LL.D., D.Sc.
Thomas Jewell Bennett, C.I.E., M.P.
Sir M. M. Bhownaggree, K.C.I.E.
Lord Carmichael, G.C.S.I., G.C.I.E., K.C.M.G.
David T. Chadwick, I.C.S.
Sir Valentine Chirol.
Sir William Henry Clark, K.C.S.I., C.M.G.
William Coldstream, B.A.
Laurence Currie, M.A., J.P.
Earl Curzon of Kedleston, P.C., K.G., G.C.S.I., G.C.I.E.
James Fairbairn Finlay, C.S.I.
Sir Frederic W. R. Fryer, K.C.S.I.
Colonel Arthur Hills Gleadowe-Newcomen, C.I.E., V.D.
Sir Krishna Govinda Gupta, K.C.S.I.
Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Sir Philip Perceval Hutchins, K.C.S.I.

S. Digby, C.I.E. (Secretary).

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

WEDNESDAY, MAY 5th; SIR HENRY TRUEMAN WOOD, M.A., Vice-President and Chairman of the Council of the Society, in the chair.

THE CHAIRMAN said it was not the first time that Dr. Mees had appeared in the Society's hall, because just eight years ago he read an excellent paper on Screen Colour Photography, for which he received the Society's medal. At that time the Lumière process had only lately been invented, and Dr. Mees gave a very interesting account of the whole method of colour photography, and discussed the technical qualities of the subject in a very clear and admirable way. Shortly after that he left England to take charge of the research laboratory which had been established by Mr. Eastman, the founder of the Kodak Company, at Rochester, in the United States, and under his care it had developed into what was distinctly the finest photographic research laboratory in the world. Those who knew Dr. Mees were sorry that this country lost the benefit of his great scientific knowledge, but he had had opportunities in America which he could not possibly have had in England, and he had made the best possible use of them.

The paper read was—

A PHOTOGRAPHIC RESEARCH LABORATORY.

By C. E. KENNETH MEES, D.Sc. (Lond.).

The Research Laboratory of the Eastman Kodak Company was established in 1912 to study the problems involved in the production and use of photographic materials.

Photographic research occupies a somewhat unique position in the field of applied science,

both because photography is so much used in other scientific work that interest in it is very widespread, and because the methods of photographic research are so different from those of all other branches of scientific work, that it is rare for the professional scientific man to understand them.

Very little work on the theory of photography has been done in the universities, and there are, perhaps, three reasons for this: In the first place, information with regard to the theory of photography is not easy to obtain; there are few books on the subject, and these deal generally with only a limited part of the field, and the original papers to which recourse must be had for information are scattered through a wide range of photographic and other journals. In the second place, work on the theory of photography necessarily involves work with photographic materials, and these materials are now made entirely by manufacturing companies, the methods of manufacture not being disclosed, so that the actual nature of the photographic materials themselves is but little understood by the user of them. In the third place, the apparatus required for photographic research is very specialised and somewhat expensive.

Our knowledge of photographic theory we owe chiefly to enthusiastic amateur photographers, supplemented in recent years by the research done by the photographic manufacturing firms, and it was in order to produce a considerable increase in the amount of this specialised photographic research work that the Eastman Kodak Company established its research laboratory.

The work of the laboratory deals, of course, not only with the theory of photography, but with many points of practical importance, both in the manufacture of photographic materials and apparatus and in their use, and the laboratory is divided into different sections corresponding to the general divisions of science, notably physics, chemistry, and practical photography, the workers in these divisions collaborating in investigation of the problems with which the laboratory is concerned.

The branches of science which are of chief importance in photographic problems are those of optics in physics, and of the colloid, physical and organic divisions of chemistry, and Fig. 1 represents an attempt to show the relations of these branches of science to photography.

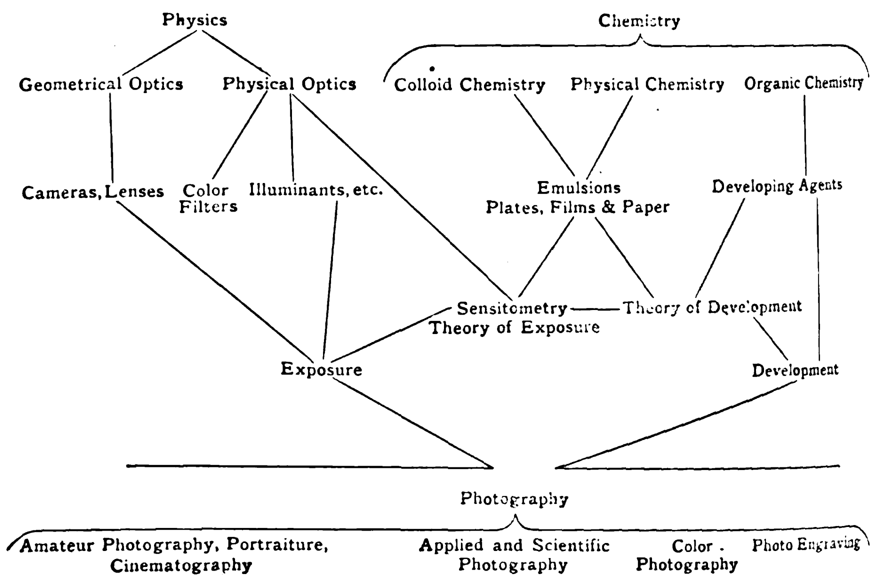

FIG. 1.

Optics deals on its geometrical side with the materials used in photography—cameras, lenses, shutters, etc.—and on its physical side with such materials as colour filters and illuminants, but especially with the study of the relation of the photographic image to the light by means of which it was produced—a study which is known by the name of sensitometry.

The manufacture of the sensitive material itself, which in the case of modern photographic plates, films, and paper, is called the "emulsion," is a province of colloid and of physical chemistry, colloid chemistry dealing

with the precipitation and nature of the sensitive silver salts formed in their gelatine layer, while physical chemistry informs us as to the nature of the reactions which go on, both in the formation of the sensitive substance and in its subsequent development after exposure.

The organic chemist prepares the reducing agents required for development, and the dyes by which colour sensitiveness is given to the photographic materials and by which the art of colour photography can be carried on. While the physicist, therefore, deals with sensitometry and the theory of exposure, the chemist must deal at the same time with the theory of development and with the conditions relating to the development of photographic images.

A laboratory, therefore, for the study of photographic problems must be arranged with a number of sections such as are shown in Fig. 2. There will be physical departments, dealing with sensitometry and illumination, reflection and absorption, colorimetry, spectroscopy and geometrical optics. There will be a department of colloid chemistry, one of physical chemistry, one of organic chemistry, one of photo-chemistry (to deal with the action of light upon a plate), and finally a number of photographic departments, dealing with photographic chemistry, with portraiture, colour photography, photo-engraving, motion picture work and X-ray work, and the results obtained in all these departments will be applied first to the theory and then to the practice of photography.

In order to concentrate the different departments of the laboratory upon the photographic problems that arise, and to ensure that on each problem the full knowledge and experience of the different specialists is made available, the main lines of work under investigation are discussed at a morning conference at the beginning of the day's work, one day of the week being assigned to each special subject, so that on Monday, for instance, those doing work in relation to one subject meet; on Tuesday the same men or other workers discuss a second aspect of the work of the laboratory, and so on. The laboratory organisation, then, resolves itself into these several groups, interlocked by their common members, who are dealing with a number of different lines of work.

The Research Laboratory was built in 1912, and occupied at the beginning of 1913. It con-

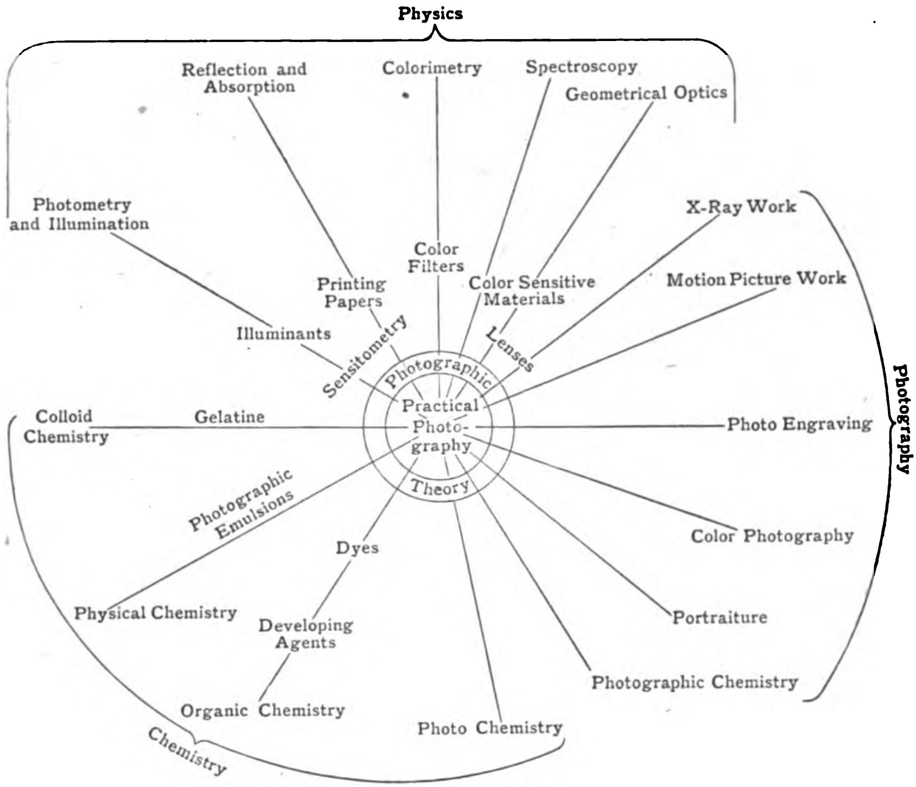

FIG. 2.

sists of a three-story building about 60 feet by 76 feet with a full-sized basement, the basement being utilised for an experimental photographic manufacturing plant. It contains in the centre a number of emulsion rooms, comprising both small rooms for individual workers and larger rooms in which operations on a semi-manufacturing scale are carried on. The basement also contains the machinery necessary for the drying of the photographic products which the laboratory makes experimentally. Since such experimental manufacturing can only be done on a considerable scale, the drying apparatus approaches in dimensions that required for a small factory. The coating of plates, films, and papers is done on the ground floor, plates being made and packed in this department, so that the laboratory is in a position to manufacture moderate quantities of any sensitive material on which it may be working. Since the machines needed for this manufacturing require skilled workers, they must be kept in daily operation. The Research Laboratory, therefore, manufactures any special products which may be required for sensitive or experimental work, and collaborates with universities and other scientific workers throughout the country. Light filters of all kinds are also made in this manufacturing department under the direct control of the research workers in the laboratory.

On the ground floor, in addition to the sensitive goods department, is a library which contains a full collection of technical works dealing with photography, physics, and chemistry; the photographic section is especially complete.

On the second floor of the laboratory building are the physics laboratory and the section of physical chemistry. The physics laboratory is divided into a spectroscopic room and computing room, a photometric room, and several dark rooms devoted to sensitometry.

On the third floor is a large projection room in which are placed the optical instruments requiring considerable length for their work. In this room are the projection machines and a lens testing bench designed and constructed in the laboratory especially for the exact measurement of photographic lenses. The apparatus for the entire laboratory has largely been designed especially for its work, and constructed in the company's machine shops.

The third floor of the building is given up chiefly to photographic work, though it contains several chemical laboratories. It includes a large studio with an artificial lighting installation, which is used for portrait and colour photography, while another studio is devoted to copying, photo-engraving and commercial photography. Other laboratories are concerned with photographic chemistry, with the physical chemistry of development, and with radiography.

Most of the chemical laboratories are apart from the main building, and include laboratories equipped for organic chemistry and for the synthesis of organic reagents. The work of the laboratory has now outgrown its building, and plans for a considerable addition have been drawn up. Until those plans can be realised in practice the overflow work from the laboratory is being housed in adjacent buildings, in order to provide for the very rapid expansion which the work continues to show.

The work of the laboratory is published in the form of scientific papers, these being printed in the usual technical journals to which the special subject of the paper may be appropriate, and then at intervals, as sufficient papers accumulate, full abstracts of all the papers are collected and published in a volume under the title of "Abridged Scientific Publications." At the time of writing, about one hundred papers have been completed.

The scientific work of the laboratory can be classified under the headings of the physics of photography, the chemistry of photography, the reproduction of tone values by photography, and work on special photographic processes, including those required for photography in natural colours. In addition to this, a considerable amount of research has been done in pure chemistry and in the various branches of applied optics, which are closely allied to photography.

The Physics of Photography.

Photographic sensitive surfaces do not consist of continuous coherent films of homogeneous material, but have a definite granular structure, the sensitive material itself consisting of grains embedded in an insensitive matrix, so that in considering the properties of a sensitive photographic material we are considering really the properties of a collection of sensitive grains, which may differ considerably from each other in their individual properties. The properties of such a collection will be the statistical average of the individuals composing it, and in order to understand the properties of a sensitive material we must therefore consider the properties of the individual grains and their

relation to the aggregate material of which they are units.

The question at once arises: Do these grains consist of crystals of pure silver halide, or of a gelatine silver complex? Microscopical study shows it to be probable that the grain is a pure silver halide crystal, for when these crystals are exposed to the action of water no swelling at all is observable, even under the highest power of the microscope. The grains of silver bromide prove to be regular semi-transparent crystals belonging to the isometric system, occurring chiefly in triangular and hexagonal tablets and in needles of various thicknesses, these needles being formed in the same way as the tablets. As they occur in a gelatine emulsion, these grains are doubly refracting, though this would not have been expected from their crystalline form. Silver bromide can be crystallised out from its solution in ammonia to show all the forms in which it occurs in emulsions, and the physical chemistry of the preparation of these crystalline grains is under investigation in the laboratory at the present time.

When the silver halide grains are developed, the crystalline form is lost, the silver being deposited in a sponge-form in soot-like particles, the form of the deposit being generally considerably distorted from the original shape of the silver bromide crystal grain, though in some cases the original shape is fairly well reproduced in the deposit of metallic silver.

In viewing a negative by transmitted light we cannot, of course, see these isolated grains with the naked eye, but we see a conglomeration caused by the penetration of light through the interstices between the grains distributed throughout the emulsion layer, and thus we obtain regular large patches of chains of grain, the pattern and regularity depending upon the particular type of emulsion used. This granularity, the formation of which can be studied by the examination of a vertical section through the film, is what is meant by the "graininess" of photographic negatives in general, and is the grain met with in enlarging, in projection, and in portraiture.

The granular structure of a photographic emulsion involves a limit to the resolving power of the emulsion; that is, it requires a certain finite distance between two points of light falling upon the film in order that they may record themselves as separate deposits of silver grains. The study of the resolving power of a photographic emulsion can be accomplished by the examination of the spread of the edge of an image. Suppose, for instance, that we lay upon a photographic film a knife edge and then illuminate this knife edge vertically from above; some of the light passing the knife edge will be scattered into the shadow by reflection from the grains of silver bromide and will produce developable grains within the shadow, so that upon development we shall obtain a distinct extension of the image beyond the edge into the shadow. If we determine the relation between the number of grains rendered developable and the distance from the edge, we shall have a relation which will depend upon the scattering of the light by the silver bromide grains and upon the absorption of that light by the grains. These two factors we might term the "turbidity" and the "opacity" of the emulsion.

An emulsion having high turbidity and low opacity will have a very low resolving power. On the other hand, even if the emulsion has high turbidity, if its opacity is also high, the resolving power may be good. A typical example of this is the wet collodion plate, in which the turbidity is considerable, but the opacity of the silver iodide for blue-violet light is so great that the resolving power is high. In the grainless Lippman emulsion the resolving power is high if the emulsion is very clear, because the turbidity is very small, but the opacity is also small, so that the slightest increase in turbidity may make the resolving power very low.

A convenient way of measuring resolving power is to photograph a converging grating, observing the point in the photograph at which resolution first occurs, and from this a numerical measurement of the resolving power can be obtained.

The importance of photographic resolving power in relation to many branches of scientific work, and especially spectroscopy and astronomy, is obvious, and much work is being done in the laboratory upon these applications.

The study of the relation between the exposure of the photographic material and the blackening produced after development is generally termed "sensitometry," since this study was first undertaken by Hurter and Driffield in 1890, in order to determine the sensitiveness to light of photographic plates. The blackening is stated in terms of the optical density which is proportional to the mass of silver present in a unit area. The photographic material, plate, or film is given a series of increasing exposures so that after development a number of steps of density are produced, each step corresponding to a certain

level of exposure. The density is then measured optically and plotted against the logarithm of the exposure, by which means a curve is obtained which, for the greater part of its length, is a straight line, though at the beginning and end it departs from rectilinearity. The curves obtained in this way are known as the "characteristic curves" of the material. (See Fig. 3.)

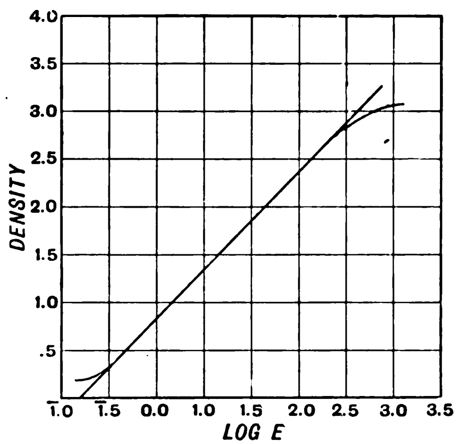

FIG. 3.

At the beginning of the curve, in what is termed the "period of under-exposure," the density increase grows until it reaches a maximum, corresponding to that of the straight line portion where the increase of density is proportional to the increase in logarithmic exposure, and at the top of the curve in what is termed "the period of over-exposure" the increase of density lessens until finally the density becomes constant. This constancy continues for a long period, after which reversal sets in. Such curves are known as the characteristic curve of the materials.

Inasmuch as emulsions are not homogeneous, but each emulsion contains grains of all sizes and of varying sensitiveness, the shape of the curve will depend upon the distribution of the different sizes of the grains in the emulsion. With a homogeneous emulsion we should have a simple curve with short over- and under-exposure portions, and by adjusting the sizes of grain so that there is a sufficient distribution of smaller and larger grains around the mean size, we can diminish the size of the under-exposed portion and obtain a longer straight line portion to the curve.

THE CHEMISTRY OF PHOTOGRAPHY.

While the grain structure of the emulsion and its reaction to light must be considered a branch of physics, the development of the emulsion is certainly closely related to physical chemistry. One of the most interesting pieces of work in the laboratory has been the study of the photographic developers in relation to their behaviour in the development of the latent image, and the relation of the constitution of the many possible compounds to their properties is being attacked in the laboratory by the collaboration of the department of organic chemistry, which prepares the compounds in question, and of a special laboratory which deals with the physical chemistry of developers. In this laboratory the developers are examined both by their action upon the photographic emulsion and also by the recognised methods of physical chemistry. The most fundamental property of a developing agent is its reduction potential, and this should apparently be measurable electrically by comparing the electromotive force produced on a platinised cathode immersed in the developing agent with the potential of an electrode charged with gaseous hydrogen.

The rate of development is dependent on two factors: first, on the rate of the chemical reaction itself; that is, on the solution of silver bromide, its conversion into metallic silver, and the precipitation of the metallic silver into a solid form; and, secondly, on the rate of diffusion of the developer to the silver bromide grain, and of the products of development away from the grain. The second of these factors has by far the greater influence in settling the rate of development, though the time of first appearance of the image appears to be dependent chiefly upon the rate at which the developer attacks the silver bromide grain. It is in the rate of attack on the silver bromide grain that the reduction potential plays so great a part, but this rate of attack under ordinary conditions is limited by the rate of solution of the silver bromide, and a developer does not attack the silver bromide grain proportionally faster by reason of an increased reduction potential.

The reduction potential of a developer, in fact, may be compared to the horse-power of an automobile, which for other reasons than the power of its engine is limited in speed. If we have two automobiles, and they are confined to a maximum speed of twenty miles an hour, then on flat roads the one with the more powerful engine may be no faster than the weaker, but in a high wind, or on a more hilly road, the more powerful engine will allow the automobile to keep its speed, while with a weaker engine the speed will fall off; we can, indeed, measure the horse-power of an automobile by the maximum

grade which it can climb at a uniform speed. In development the analogy to the hill is the addition of bromide to the developer, since the addition of bromide, by the lowering of the solubility of the silver bromide, greatly delays the chemical reaction in development, and the higher the reduction potential of a developer the more bromide is required to produce a given lowering of the density, so that we can measure the reduction potential by the amount of bromide required to produce a given effect. If we measure the common developers in this way, we shall find that glycin has the lowest reduction potential, then hydroquinone, then pyro and paraminophenol, and finally diamidophenol has the highest.

Reproduction of Tone Values.

In photography the object is to produce on the observer the same impression of the relative brightnesses of the scene reproduced in the print as was produced at the time that the photograph was taken. It is clear that a study of this can be divided into two sections, one dealing with the objective reproduction in the print of the scale of light intensity which occurred in the original subject, and the other concerned with the subjective impression produced on the observer, both at the time of viewing the subject and later when viewing the print. With regard to the objective side of the subject, let us consider first of all the way in which a scale of brightnesses is reproduced in the photographic process from the original subject through the negative to the print.

There are four separate sections involved in this investigation: first, the study of the range of brightnesses occurring in natural objects, such as one is required to photograph; second, the study of the way in which the photographic emulsion translates a scale of light intensities into deposits of metallic silver in the negative; third, the study of the properties of photographic printing papers, and the relation of the reflecting power of the deposits obtained in them to the scale of light intensities to which they were exposed; and, fourth, the study of the accuracy with which the tone values of the original are rendered through the negative on to the printing paper.

Until recently the scale of rendering of a negative material was all that had been fully investigated. This was done by Hurter and Driffield as has already been mentioned. They studied the relation between the exposure of the photographic material and the blackening produced, but in order to render possible the study of the reproduction occurring in photography, an investigation of the sensitometry of papers was also necessary.

In the first place, an instrument was designed by means of which the light reflected from small areas of the exposed print could be measured. Papers were then exposed for known periods of time, developed, the reflecting power of the developed image measured and a curve plotted of the logarithm of the reciprocal of the reflecting power against the logarithm of the exposure. (Fig. 4.) Several constants were found to ex-

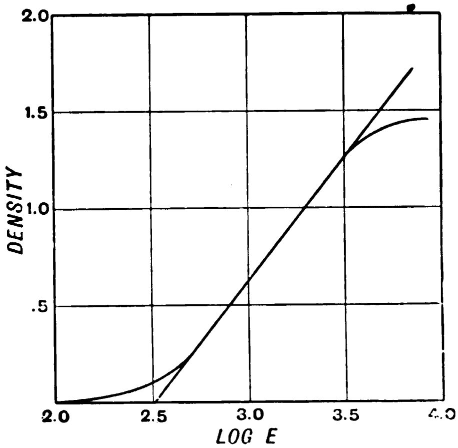

Fig. 4.

press the behaviour of photographic papers; thus, any paper had a maximum density, that is a minimum reflecting power representing the deepest black which could be obtained upon it. It showed, also, a typical scale or total range of exposures through which any difference could be obtained with an alteration of exposure. Again, the straight line portion of the curve showed a definite steepness or "gamma," as we call it, and finally the length of the straight line portion is of great importance, since it is only throughout this straight line portion that exact reproduction can be obtained.

The method of obtaining the sensitometric characteristics of a positive material having been developed so that the results obtained were satisfactory, it remained only to combine this information with that relative to the characteristics of the negative material in order to obtain a solution of the objective phase of the tone reproduction problem. A graphic method was, therefore, developed by means of which this desired result could be accomplished. By use of this method it becomes possible to compute from the known or easily measurable factors,

such as the brightnesses in the object, the constants of the image forming system, the illumination used in making the positive, and the intensity of illumination incident upon the positive during observation, the brightness values in the positive by which the various areas of the object are reproduced. By comparing these brightness values with those of the object, a quantitative expression of the quality of objective reproduction obtained can be formulated. This solution of the objective phase, however, is not all that is desired, for as previously stated, the object in most cases of photographic work is the reproduction of the group of sensations resulting from an observation of the object.

In order to obtain the data necessary for this solution, a large amount of work has been done on visual sensitometry, which deals with the determination of the various sensibility functions of the human eye. The data of particular importance in this case are those relative to the various brightness sensibility functions, especially that relative to contrast sensibility. These data having been obtained, the graphic solution was extended so as to include also the subjective phase, and by the method as finally worked out it is possible to obtain a graphic representation of the quality of subjective reproduction. This is expressed by evaluating the characteristics of the subjective reproduction in terms of the subjective object, and expressing this evaluation as a function of the brightness in the original object.

Many interesting conclusions, some of considerable practical importance, have been drawn as a result of the work on this tone reproduction problem. Among these may be mentioned the relation which should exist between the negative and the positive material upon which it is to be printed, which may be stated by saying that the density scale in the negative should be equivalent to the exposure scale of the positive material on which the print is to be made. Another point of considerable interest, and relating particularly to the subjective phase of the subject, is that an enhancement or increase of objective contrast in the print may frequently be necessary in order to reproduce apparent contrast in the object, this being due to the fact that the contrast sensibility of the retina may be relatively low when viewing a print under a low illumination, while on the other hand the contrast sensibility is high when the observer views a brilliantly illuminated object.

Practical Photography.

Naturally, a great portion of the work of the laboratory is concerned with photographic processes, and work on all kinds of photographic processes is continually in progress. It is difficult to summarise this work in any brief form, but the work which is being done on colour photography is perhaps especially worthy of note.

There are two main divisions of the practical processes of colour photography; the processes which are known as "additive," in which the colours are produced by the superposition upon a projection screen or in the eye of beams of the primary colours; and the "subtractive" processes, in which negatives taken through the primary filters are printed in colours complementary to those filters, and these prints are then superposed.

Most of the work of the laboratory has dealt with the subtractive processes, though a good deal of research work has been done upon the filters required for the additive processes and upon such subjects as the colour of mixtures of two nearly complementary colours, work which is of considerable interest in connection with the two-colour additive processes.

In work on the subtractive process of colour photography, some interesting results have been achieved in the photomicrography of stained sections, a two-colour process having been developed which gives very good results for this purpose. The two-colour subtractive process of colour photography has also been applied to motion picture work, the pictures being made by using film coated on both sides with a sensitive emulsion, so that negatives taken through the red and green filters can be impressed in register on opposite sides of this double-coated film, and then the double images after development can be transformed into dye images complementary in colour to the filters through which the negatives were taken. In this way each picture on the film consists of two pictures of complementary colours, which give the effect of a two-colour subtractive picture. This process, of course, has the great advantage that film so made is suitable for projection in any ordinary motion-picture machine.

Owing to the intimate relation of photography to physics and chemistry, a great deal of work has been done in the laboratory in these sciences: thus in applied optics a number of studies have dealt with the reflection and transmission of light by diffuse media and with brightness measurements, the laboratory being especially

well equipped to study absorption photometry, both with and without the consideration of colour. The study of colour itself occupies a large part of the activities of the physics department; measurements have been made on the sensibility of the eye to colour and to change of hue, and a number of investigations have been made on the use of the monochromatic and other colorimeters for the quantitative expression of colour. In physical chemistry studies have been made on the physical-chemistry of gelatine and other allied colloids, and a monograph on gelatine is now in preparation. Methods of measuring viscosity, turbidity, swelling, and other physico-chemical constants, have been developed in this department. In electro-chemistry also a great deal of work has been done. New methods for the electro-analysis of silver solutions have been worked out, apparatus for the determination of hydrogen potential has been designed, and methods for the precise determination of conductivity have been developed.

A special department of the laboratory deals with the production of synthetic organic chemicals, its purpose being to supply the lack of those materials, so essential for the research worker in organic chemistry, which we formerly obtained from Germany. A price list containing about 700 organic chemicals has been issued, and this department of the laboratory promises eventually to become a full-fledged manufacturing department, supplying synthetic organic chemicals to the universities and the laboratories of the United States.

The division of organic chemistry was concerned during the war chiefly with the production of developing agents and dyes to replace those which had been previously purchased from Germany, but it is an important section of the photographic research laboratory, since chemistry is concerned with so many sections of the laboratory's work. The whole organisation of the research laboratory, however, is really a section of a wider division of the Company's activities, since it is a part of the Development Department, which is responsible for the introduction and development on a manufacturing scale of new products of all kinds. The Development Department contains other sections in addition to the laboratory itself, experimental shops in the camera factories where apparatus is built, and departments for the study of inventions submitted from outside or of suggestions originated in the Company. All work done in the Research Laboratory which can be used in the Development Department is at once referred to it, and the completest co-operation is ensured by the control, both of the laboratory and the Development Department, under the one head.

DISCUSSION.

THE CHAIRMAN (Sir Henry Trueman Wood) said the question of industrial research was now one in which the public took a great interest. We had had a lesson from Germany as to its value, and the man in the street was beginning to realise what had been known for years past to the man in the laboratory. The Government had established a special department for industrial research, and was encouraging the development of laboratories in various branches of trade. There was one objection to the industrial trade laboratory; it must be founded for the benefit of the particular business supporting it, and naturally that individual or company would be very apt to preserve extreme reticence as to the result of its work; it desired to keep its information to itself, and not let its rivals have the benefit of it. That had been very marked in German laboratories. But there was another side to the question, namely, that although the particular business might gain a great deal by keeping its results to itself, it would gain more in the long run by the publication of the results and by the general advance in the progress of the business. He thought it was quite clear from what the author had said about his own laboratory that that view was taken to a very large extent by those who started it. Photography as an industry was comparatively small, but from first to last it had been a purely scientific business and had developed on purely scientific lines. The results of scientific advance had been to build up large commercial businesses, of which that with which Dr. Mees was connected was one of the most important. He had shown that they were doing very valuable public work, and it was to be hoped that their example would be freely followed by those who were engaged in establishing similar research laboratories in this country. He thought it was being realised that better results would be obtained by throwing all the knowledge into a common stock than by trying to keep it to individual firms.

MR. W. B. FERGUSON, K.C., said he had the honour of being a member of the Council of the British Research Association—in fact, he was a Vice-President of the Photographic Research section—and he had been deeply interested in listening to Dr. Mees's paper and in seeing the pictures that had been shown. It was extremely to be regretted that the Americans had taken from this country the one man who was entitled to be considered the head of photographic research. In all research associations the great difficulty was to get hold of the Director of Research. A real director must be one who not only was acquainted with the physics and chemistry of photography, but also had some knowledge of photography

itself and the actual manufacture of photographic materials. Dr. Mees combined all those qualities. One thing about Dr. Mees was that he made no secret of his discoveries, and would tell one anything he knew. That was a rare quality in scientific men connected with trade associations. Dr. Mees had alluded to the great difficulty in finding records of research work done by former chemists and physicists. He might point out that the Royal Photographic Society had latterly published a collective volume of the research work of Messrs. Herter and Driffield, and had also added a large bibliography of the scientific work done in photographic research from 1890 until two years ago, and he thought that book would be of considerable help to those engaged in photographic research. With regard to the Photographic Research Association, it started with laboratories at University College, had a good Director of Research and valuable assistants, and a good deal had been done, but after going on for about a year, a large chemical manufacturing firm offered the Director of Research a salary which the Research Association could not afford to pay, and naturally he had gone to the works. At present the Association was on the look out for another man, and he only hoped they would succeed in finding a man with the various qualifications that Dr. Mees had described and which he possessed in the highest degree.

Mr. George E. Brown said there was one thing that might be brought to the notice of Dr. Mees, and that was the opportunity which he had in his research laboratory of enriching the English literature of photography—the general literature of photography—to which those who wished to learn would naturally turn. The English literature in that connection was a deplorable collection. If one wanted to find anything one had to go to French or German literature. Probably no one man could write a series of books which represented the knowledge of photography at the present time, but he thought it could be done by a company of men such as Dr. Mees had gathered round him.

The Chairman, in proposing a vote of thanks to Dr. Mees for his paper, said he was one of the very few men who was thoroughly competent to run such an institution as the research laboratory of which he was the head, and which he believed owed its great success to his admirable organising capacity and his very wide and extensive scientific knowledge. He only hoped it might be possible to obtain someone as much like him as possible for the photographic research laboratory in this country.

The motion was carried unanimously.

Dr. Mees, in reply, said he could not express too strongly what he felt with regard to the publication of the results of research associations, industrial or other. A research laboratory that did not publish was half dead; it was not very much good being alive if one was blind and dumb. Also, it was no good being alive if one was devoid of all means of expression, even if one could receive information, because if a man had ceased to give out information for a sufficient time he would not be interested in receiving it. The primary object of publication by a research association was to keep the men alive. If the association obtained good men from a university, keen on scientific work and accustomed to research and to free discussion, and put them into an institution and told them that they must not say anything, it was putting them into a tomb, and the men after five years ceased even to read scientific papers. They had no incentive to do so. The men in his laboratory had a very good incentive, because they were going to be criticised. He had been rather horrified at the theoretical attitude of the British research associations generally. A great deal of stress was laid on the possibility of secrecy, but he hoped they would not insist on that, because if they did they would be dead before they were born. The great difficulty in research work was to make anybody take notice of it. People were busy, and the first impulse was to take the elaborate report that had been sent to them and pigeon-hole it. It was necessary that the laboratory should not only create its new scientific knowledge, but interpret and apply that knowledge. It might start with a paper like the one he read to the Royal Photographic Society on the previous evening, on the reproduction of tone values, and after some years that would be applied to the Kodak user. The whole of that work had to be done by the energy and under the guidance of the laboratory men. They patented everything they could patent, but if a thing could not be patented it was published. Even the German firms patented and published, and the great dye works patented or published everything. A great many stories had been told about German secrecy, but all that had to be read through the war haze. As a matter of fact, the German dye works had published more chemistry than all the other agencies in the world put together, and the greater part of the German laboratories were continually publishing. One of the greatest scientific institutions in the world, the Zeiss works, were publishing all the time. It was only by such work, published freely and frankly, that industrial laboratories could come into their own in the scientific world. He did not agree with the Chairman that photography was a very small industry. In the paper he had included motion pictures as a branch of photography, and in the United States that was stated to be the fifth industry in the country, and came under the same order as textiles. The factories of Rochester made 5,000 miles of that film a day. He wanted to disclaim responsibility for what was put on the stuff afterwards! He was glad to be reminded by Mr. Ferguson that he had made a mistake in the paper. When he wrote the paper he had not seen the Herter and Driffield Memorial volume, and

did not know there was a bibliography of the entire subject of photographic science. It was a monumental piece of work of the greatest value. Mr. Brown's remarks on photographic literature were entirely correct, although he could not help wondering that a man who had been the editor of a photographic paper for so many years should still remain an optimist. The idea of any member of his staff writing a book that Mr. Brown would approve was inconceivable. They could write monographs, but the translation of them into ordinary English was not going to be done by the man who wrote the monograph. The question of clear, good books on photography was a very difficult problem. It might interest Mr. Brown to know that one of his books, called "The Fundamentals of Photography," which was written for the Kodak user and dealt with pure theory, had been published by the Company. Personally, he thought it would be necessary to look to people other than the men who were doing scientific research to give an account of it in plain, simple English for the public. The difficulty was that all the men engaged on research assumed that people who were reading the papers understood all the technical terms that were used.

The meeting then adjourned.

THE ITALIAN QUICKSILVER INDUSTRY.

Monte Amiata, situated in the Grosseto-Siena region, is the centre of the Italian quicksilver industry, and the output from this district represents approximately the national production. The ore-producing zone stretches for 40 kilometres in a direction parallel to the Apennines, and covers an area of 400 square kilometres. The entire region is mineralised, but only special pockets are sufficiently rich in ore to repay the cost of working. There are at present eight active mines. Three mines have lately been worked out and abandoned, but have been replaced by bringing in two new ones.

The most important deposit is red sulphide or cinnabar. Sometimes, but very rarely, the liquid metal is found in the form of minute drops. The wealth of the deposits does not increase with the depth of the mine, but exhausts itself at no great level. The work of extraction ceases at a depth of about 200 metres. The relative superficiality of cinnabar deposits is characteristic of mercury mining the world over. It is an advantage so far as prospecting and operation are concerned, but a drawback in shortening the life of the mine.

The future of the Monte Amiata region, writes the United States Commercial Attaché at Rome, lies in the extension, rather than in the depth, of the producing zone. Experts estimate that the region will continue to supply ore in undiminished quantity for several centuries to come. This, however, is dependent upon the discovery and exploitation of new beds. Under present conditions of abnormally high fuel and labour costs, only the richest deposits are being worked at a profit. Cheaper processes of production may be devised that will render available vast deposits of low-grade ore that are not workable at present.

The high cost of fuel is the heaviest item of expense in ore reduction. The ore is always treated on the spot, being first dried in the sun on platforms or in artificial desiccators. The old type of distilling retort ovens has been given up; they were dangerous because of their mercurial fumes and uneconomical because of waste. Two types of ovens are now in use—one for the treatment of large fragments of ore, which are mixed with charcoal in simple tank ovens, and special drop or rotating ovens for treating smaller fragments of ore. Both these types minimise dispersion, but require great quantities of fuel, both wood and charcoal. In addition, enormous quantities of timber are used as mine props for sustaining the galleries. The double call on timber for charcoal and mine props has made a devastating inroad on the scanty forest resources of the surrounding country. It is now proposed to prevent this excessive use of wood by the installation of electric ovens for ore reduction. Water power from the Apennines is available for hydro-electric energy, but electric smelting has not come up to the high expectations of its proponents.

Two minor difficulties add materially to production costs: (1) The emanations of sulphuretted hydrogen, necessitating the extensive use of electric ventilators; (2) the character of the soil—occasional strata of loose soil are encountered, which become saturated with water and cause the galleries to cave in.

The number of workmen employed in the Monte Amiata mines is about 900.

The production of mercury in these districts in 1915-18 was as follows:—

	Ore. Tons.	Metal. Tons.
1915	110,612	985
1916	132,524	1,093
1917	113,782	1,071
1918	—	1,038

The production of mercury (metal) in Idria in 1918 was estimated by the Italian Bureau of Mines to have been 600 tons, making the total output of Tuscan and Idrian mercury for the year 1,638 tons.

During the war, the Italian Government took over the entire output of mercury at 12 lire per kilo, and fixed the selling price at 25 lire per kilo. It is understood that there is a relative decline in Spain's production. Mercury is the one mineral, with the exception of sulphur, that Italy produces in considerable exportable amounts.

A proposal has been put forward by the director of the Monte Amiata mines, with the backing of three great Italian banks, for the formation of a mercury combination for the control of the world's supply. The "trust" would be composed of the Monte Amiata and Idria mines, and also the principal mines in Spain.

The quicksilver industry in Italy before the war was financed by German bankers. During the period of Italy's neutrality, control passed to Swiss financiers. Within the last two years Swiss money has been replaced by Italian under the leadership of the Banca d'Italia.

The Monte Amiata company is now purely Italian. Prospecting by Italians for new quicksilver deposits is busily going on in Dalmatia and in the Trentino.

OBITUARY.

Isham Randolph.—Mr. Isham Randolph, an eminent member of the engineering profession in the United States, died at Chicago on the 22nd ult., in his seventy-third year.

Perhaps his principal achievement was the Chicago drainage canal, which cost £12,000,000, and has a hydro-electric plant developing 40,000 h.p. Another notable piece of work he accomplished was to make a dam on end at the brink of the Niagara river, and then tip it so as to fall in the requisite position to check the serious erosion of the river bed above the Horseshoe Fall. As a member of the international board of consulting engineers for the Panama Canal, he signed the minority report which was accepted by President Roosevelt, approved by the Canal Commission, and adopted by Congress. Mr. Randolph was also on the board of advisory engineers who upheld the plans for a lock canal. He was elected a Fellow of the Royal Society of Arts in 1916.

GENERAL NOTES.

Research Department.—Professor J. B. Farmer, F.R.S., has been appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research. The British Launderers' Research Association, having complied with the conditions laid down in the Government scheme for the encouragement of industrial research, has been granted a licence.

Cotton-Growing in Mesopotamia.—Since 1917 experiments have been conducted by an expert from the Indian Agricultural Service with a view to discovering the most suitable kinds of cotton to grow in Mesopotamia. The results of the work done in this connection, and the prospects of establishing a cotton-growing industry, are fully dealt with in the current number of the *Bulletin* of the Imperial Institute. So far, American types of cotton seem to be the most suitable. The members of a deputation of the British Cotton-Growing Association, which visited the country towards the end of last year, were very favourably impressed with its possibilities for cotton production. The acreage eventually planted will depend on the quantity of labour available and the area on which a perennial supply of water can be guaranteed. It seems likely that a total of 150,000 to 200,000 acres could be cultivated annually by the existing population if the necessary facilities, in regard to agricultural machinery, transport, etc., were provided. At a low estimate this area should produce from 15 to 20 million pounds of cotton yearly.

Electrification of New Zealand Railway.—The English Electric Company has been awarded a contract for the electrification of a section of the Midland Railway of New Zealand. His Majesty's Trade Commissioner at Wellington, in cabling this information, says that special importance is attached to this contract, as it was obtained on the merits of the tender in the face of strong American competition. The section to be electrified includes a tunnel over five miles long, and three steel bridges. A great portion is on a grade of 1 in 33, and the summit is about 2,400 feet above the sea-level. The system to be used is 1,500 volts direct current overhead contact. This is the first railway electrification in the Dominion.

Conveying Milk through Pipe Lines.—The transport of milk by pipe lines, says *Engineering and Industrial Management*, is under consideration in Germany. It has been ascertained by experiments that the method must be one of high pressure through relatively small pipes, and since the milk does not come in contact with air and bacteria, it is said to be immune from deterioration and the method absolutely hygienic. The obvious fear that casein may segregate and block the pipe line has been shown to be technically irrelevant, as no such deposits can form unless by some carelessness sour milk should be admitted into the pipe line, but even in such an eventuality the rinsing with an alkaline liquid would dissolve and remove such deposits. This matter has been taken up by the German Agricultural Society, and it is intended to convey the milk by such means from rural collecting centres to distributing depots in towns.

Rubber-Seed Oil in Sumatra.—After extensive investigations in Sumatra and the Federated Malay States, the conclusion has been reached, according to a report from the United States Consul in Sumatra, that it would not be to the advantage of the rubber plantations to collect seed specially for the purpose of extracting oil therefrom, and that Hevea seed would become profitable only in connection with oil from other products. At present there is no machinery for extracting this oil on the rubber estates, and the Director of the Experiment Station is of opinion that it would not pay to install such machinery unless other oil-bearing seeds could be produced in the same locality. Nor would it be considered profitable to export the seeds, as the bulk is great in proportion to the small content of oil.

Journal of the Royal Society of Arts.

No. 3,540. VOL. LXVIII.

FRIDAY, SEPTEMBER 24, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

SPECIAL MEETING.

On FRIDAY, OCTOBER 15th, MR. THOMAS M. AINSCOUGH, O.B.E., His Majesty's Senior Trade Commissioner in India and Ceylon, will read a paper on "British Trade with India."

The chair will be taken at 4.30 p.m. by SIR CHARLES C. MCLEOD.

INCREASE OF SUBSCRIPTION.

At the Annual General Meeting, held on June 30th, it was unanimously resolved that the annual subscription of Fellows be increased from £2 2*s.* to £3 3*s.*, and the Life Composition fee from £21 to £31 10*s.* The new scale will apply to all subscriptions due on and after Michaelmas, 1920.

These changes have been necessitated mainly by the great increase in the cost of the *Journal*, which rose from £1,767 4*s.* 11*d.* in 1913–14 (the last year before the war) to £2,851 11*s.* 10*d.* in 1919, and will probably rise further to about £3,800 for the current year. The general costs of maintenance and of conducting the work of the Society have also inevitably risen. Further particulars as to the financial position of the Society were published in the report of the Annual General Meeting in the *Journal* of July 2nd.

COLONIAL SECTION.

The Colonial Section Committee, as appointed by the Council, is as follows:—

Alan A. Campbell Swinton, F.R.S. (Chairman of the Council).
Lord Blyth (Chairman of the Committee).
Marquess of Aberdeen and Temair, P.C., K.T., G.C.M.G., G.C.V.O.
A. H. Ashbolt (Agent-General for Tasmania).
Sir Charles H. Bedford, LL.D., D.Sc.
Byron Brenan, C.M.G.
Richard Ernest Brounger.
Sir William H. Clark, K.C.S.I., C.M.G.
Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.
Hon. James Daniel Connolly (Agent-General for Western Australia).
Hon. Sir John A. Cockburn, K.C.M.G.
Sir Edward Davson.
Edward Dent, M.A.
Sir Walter Egerton, K.C.M.G., LL.D.
Right Hon. Andrew Fisher (High Commissioner for Australia).
W. L. Griffith.
J. McEwan Hunter (Agent-General for Queensland).
Lord Inchcape, G.C.M.G., K.C.S.I., K.C.I.E.
Hon. J. G. Jenkins.
Major Sir Edward Humphrey Manisty Leggett, R.E., D.S.O.
Hon. Edward Lucas (Agent-General for South Australia).
Hon. Sir Peter McBride (Agent-General for Victoria).
Sir George Robert Parkin, K.C.M.G., M.A., D.C.L., LL.D.
Sir Westby B. Perceval, K.C.M.G.
Sir Robert W. Perks, Bt.
Hon. Sir George Halsey Perley, K.C.M.G. (High Commissioner for Canada).
Right Hon. Sir Joseph West Ridgeway, G.C.B., G.C.M.G., K.C.S.I.
Lieut.-Colonel Sir Thomas Bilbe Robinson, G.B.E., K.C.M.G.
Lord Sanderson, G.C.B., K.C.M.G.
Sir Thomas Sutherland, G.C.M.G., LL.D.
Carmichael Thomas.
George Wilson, C.B.
Sir Frederick W. Young, M.P.
S. Digby, C.I.E. (Secretary).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

RECENT RESEARCH IN CELLULOSE INDUSTRY.

By CHARLES FREDERICK CROSS, B.Sc., F.R.S.

Lecture I.—Delivered February 16th, 1920.

LIGNOCELLULOSE TYPES.

The subject of the present essay is a perennial source of interest to a very wide and varied range of readers and workers; it is so in the nature of things, and for reasons so fully recognised, as to require only this bare comprehensive mention by way of preface, with an illustration which, if personal, is apposite. It is just forty years since the publication of a paper on the "Chemistry of Bast Fibres," recording the results of the early work of my partner Mr. E. J.

Bevan and myself in this field, a tentative essay communicated to our fellow-students of the Owen's College Chemical Society (April, 1880, Chem. News, 42, 77).

In this essay, establishing some fundamental quantitative relations of lignone and cellulose in the jute fibre (lignocellulose), we made mention of a phenomenon well known in the jute industry, the destructive damage of the fibre which occurs from time to time in the press-packed bales in course of transit from India and storage, and is known as "heart damage."

The chemical constitutional features of this structural breakdown were more fully dealt with in a later paper (J. Chem. Soc., 1882, 41, 90). It did not require much imagination to recognise in this phenomenon, and its attendant results, an opening of the science of the subject from the "natural" side, and therefore with promise of fuller revelation of constitutional factors than by way of laboratory methods of resolution by reagents. Further, there was and is, a very obvious industrial-commercial aspect of the matter, involving as it does, material values and business interests.

But the "interests" were not interested, and "science" was preoccupied with the intensive following up of its systematic developments. Moreover, the authors were feeble folk, or student adventurers on the ocean of knowledge, and so the opportunity was pigeonholed.

About the year 1907, the matter was revived, but from the more "practical" side, presumably an epidemic of "damage," and we were asked by the Indian Government to investigate the matter from this point of view.

In association with Mr. Finlow, the Government fibre expert, these investigations have been mainly directed to establishing the range of "normal" moisture within which the fibre in the press-packed condition of the commercial bale is immune from damage under the ordinary conditions of transport and storage. The results are recorded in two reports, printed and circulated by the Government Department. In the one (Cross and Bevan, 1908), the chemistry of the damage is further elucidated, and in the other (R. S. Finlow, Memoirs, Dept. Agr., India, Vol. v, No. 2, 1918) it is finally established:—(1) That the limit of moisture beyond which there is liability to the particular damage is at 25-30 per cent., the limit varying with the degree of compression of the fibre in the bales; (2) that the active agency in initiating the breakdown of the fibre substance is bacterial development; (3) that the mould growths, which are a frequent visible evidence of the "organic" nature of the damage, are a secondary effect, due to the breakdown products providing a nutrient medium for growths. The more prevalent organism of this class has been identified as *Aspergillus fumigatus*.

We mention this matter by reason of the typical significance of its history. During a period of forty years a problem of far-reaching scientific importance, and of obvious practical incidence, has been able to inspire two officially delimited investigations, limited, that is, to the latter which is the "practical" commercial issue. By contrast, the issues involved on the scientific side are of wide and presumably absorbing interest:—

(1) The chemical constitution of the fibre substance, cellulose and lignone, and their mode or condition of union as lignocellulose.

(2) The equilibrium of the lignocellulose system in relation to water, oxygen, micro-organisms, and the forms of energy which are operative in the organised system of the plant, and in modified degree after separation from the plant.

(3) The structural modification of fibres and tissues determined by lignification, and the correlative variation of (2) with degree of lignification.

These primary problems have been the subject of detached investigation during the period 1880-1920, the more important of which are described in "Researches on Cellulose" (Cross and Bevan, 1895–1910), and subsequently in "Lignone Reactions and Constitution" (J. Soc. Dyers, Col. 32, 1916).

In view of the special purpose of these lectures, it is necessary to assume that audience and readers have more than general knowledge and interest in the subjects treated, in order to give prominence to a rather "impressionist" survey, with indications of the sectional research fields, innumerable, which await the workers of this generation.

On the other hand, to attempt a systematic or encyclopædic treatment would sacrifice an opportunity in conforming with the convention of the prosaic order of the text books.

It appears that in the present phase of re-discovery, even the journalist order of mind is awakened to the importance of "cellulose," the textile fibres, the more massive products of plant life, and the colossal interests which may be connoted.

As to the complementary perceptiveness of their prospective relationship to natural science,

it would appear from the constitution of industrial research associations, under Government auspices, that the official mind is awakened to the country's systematic neglect of the obviously genetic relations of science to progressive industry. But it is doubtfully alive to the more positive philosophy of the matter, which may be summed up in a paraphrase: "Take thought of science, and all those things shall be added."

The further consideration of some aspects of the lignocellulose problems is thus intended to be suggestive of prospective developments.

The lignone component is a complex of which, as constituent groups, there have been diagnosed a diketo-hydrobenzene, a hydro-pyrone, and ketene ($-CO-CH_2-$) molecules, *i.e.*, residues (J. Soc. Dyers, Col. 32, 1916).

The union of lignone with cellulose to constitute the lignocellulose is now accepted to be of the order of adsorption compounds.

The intimate association of the saturated polyhydroxy cellulose group with the unsaturated lignone complex, suggests a system capable of interior exothermic rearrangements.

The investigation of the heart-damaged jute, reveals such changes to new complexes without changes of elementary composition. The characteristics of the water soluble products are acidification, definite transitions to aromatic hydroxy derivatives, and to derivatives which appear to be keto-aldehydes.

Accepting such evidences as the basis of working hypotheses, they provide a *point d'appui* for the investigation of the issues above formulated.

Grouped with these are other physiological problems, *e.g.*, the origin of the lignone complex, and its relation to the tannins and such aromatic complexes—phenol-pyrone derivatives—as are characteristic of the dye-woods. Nor can we overlook, in the sense of taking for granted, the structural modifications characteristic of lignification. Lignified fibres and tissues are relatively rigid and inelastic. Moreover, lignification of fibre cells is invariably associated with units of small dimensions.

The problems of these relations have been in the field of investigation for many years, but workers have been waiting for opportunity or inspiration. As an illustration, attention may be directed to a recent Royal Society paper by Professor Robinson (Nov. 1919). Investigating the effects of strain upon wood structures, such as are used in aeroplane construction, he has shown that deformation under pressure is attended with de-lignification, a separation of cellulose from lignone. Also, that the lignocellulose behaves as a fluid or liquid system. These points we shall refer to in a subsequent lecture. The immediate objective of this investigation was obviously technical, but the result was recognised as a contribution to pure science. This is worthy of incidental mention in illustration of a general trend. Industry and manufacture are teeming with research problems. The problems are many, but the science is one.

Professor Robinson investigated a detached problem and the scientific results are closely co-ordinated with progressive work on apparently quite independent lines of research.

Thus an adsorption compound of lignone and cellulose is obviously open to fractional resolution, by physical process. The result under discussion is a confirmation of this more recent theory of lignocellulose matter.

The fluid characteristics of lignocellulose emphasised by Professor Robinson's observations, accord with our observations in various directions converging in the inference that the vegetable fibre substances are to be regarded as liquid systems (J. Soc. Dyers, Col. 35, 1919, 270), characterised by considerable volume changes under reaction with water, and also with changes of temperature, on which view the intimate interpenetration of the cellulose and lignone systems in the histological processes of formation is brought a step nearer to our comprehension, with suggested lines of investigation.

But the problems of the more advanced type of lignification, characteristic of the perennial woods, are much more complex than those of annual crop plants. In this region also there are well-known processes of breakdown, under the attack of organisms, which urgently call for systematic study, since the products must represent new equilibrium phases of the component groups.

In the middle period of our research work in this field we were in active correspondence with Professor Crié, at that time of Rennes University, who was appointed by the French Government to study the phenomena of decay of forest trees (*Dépérissement des Arbres*). We examined several specimen products; characteristic results in particular cases were:—

(*a*) A pine wood:—

Moisture in air dry state . . .	10·0
Soluble in 1 per cent. NaOH .	98·3
Furfural	0·8

(*b*) A hazel wood, with patches of a bright blue colouring matter, soluble in alcohol.

The alcoholic solution contained a notable proportion of aromatic compounds with reactions of the gallo-tannins.

(*c*) An oak wood, in an advanced condition of disintegration, with a high proportion of water-soluble derivatives. The residue from exhaustive treatment by water was quantitatively investigated, and the main chemical constants were closely similar to those of the original wood substance. Whereas wood substance is evidently endowed with extraordinary resistance to destructive breakdown, it is equally evident that a change of condition, slight in regard to calculable chemical effect, initiates down-grade modifications.

A case in point, also noteworthy as arising in connection with industries, is the breakdown of "mechanical" wood pulp stored in the moist condition. Although by no means a rare occurrence it has been little investigated. In 1908, following our report (*supra*), we received a communication of details of an investigation of "rotten" wood-pulp from Mr. F. Barnes, at that time chemist to Messrs. Ed. Lloyd and Co., Ltd.

The degradation of the pulp affected massive quantities, 4 cwt. bales were found to be attacked throughout.

It was noted that these extreme effects were in bales in the middle of the stacks of pulp, therefore, in the words of Mr. Barnes's note, "the whole stock may be considered as one bale," and this suggestively links the observations and investigations with the "heart damage" of jute lignocellulose in the bale.

The following important points were established:—(1) Particular sheets of pulp were made up of (*a*) white undamaged pulp; (*b*) grey and rotten pulp; (*c*) red-brown and rotten.

Water Soluble Compounds in (a) 1·0 to 2·0 per cent., had become 14·0 to 25·0 per cent. in (*b*) and (*c*) with the high "sugar" value (cupric reduction) of 30 to 40 per cent.

Furfural Constants in (*a*) 4·4 per cent.: in the *water-soluble*, from (*b*) and (*c*) similarly 4·4 per cent of total dissolved substance, whereas in the original specimens of degraded lignocellulose, the percentages were in (*b*) 2·5, in (*c*) 2·12.

The chemical changes in the complex are of exactly the same order as in the "annual" lignocellulose.

There are obvious inferences from these observations. The papermaker's loss is the agriculturalist's prospective gain. Cellulose "degradation" is the obvious preparation for assimilation, *i.e.*, re-assimilation.

The economic questions arise:—(1) in which direction would such matter be more advantageously used, as plant food or as a nutrient for animals?

(2) If usefully available, how can the transformation be industrially worked on one of the world's gigantic wastes, sawdust, and the many similar rejecta of the wood working industries?

Incidentally to this discussion there must be mentioned:—

(1) Recent developments in the utilisation of wood cellulose as cattle food (J. Soc. Chem. Ind. 37 (1918), 437 R).

(2) A process for treating wood residues to transform the lignocellulose into assimilable material which was worked for some time in this country, the product being used as a component of cattle food mixtures, sold under the trade name of "Bastol."

The process is known as the "Classen" process (H. Classen, in U.K. Pat. 12588 (1901); J.S.C.I., 1901, 1008).

The active agent used was sulphurous acid, applied in an atmosphere of steam to the sawdust contained in a digestor. By the treatment a proportion of the lignocellulose, about 20 per cent. was brought into water soluble form, with a high "sugar" value.

It was claimed for the remainder that though insoluble it was nevertheless for the most part assimilable in the digestive tract of the animal.

It would be outside the scope and purpose of these lectures to press this discussion to any formal conclusion. We are dealing with undeveloped lines of investigation converging in a main suggestion, that the more resistant lignocelluloses are capable of transformation to proximate products of industrial value. The transformations already investigated involve the "destruction of material used, and valuable for structural purposes." From the point of view of the industries involved they are "damages"; from the complementary point of view of other industries they are constructive transformations.

A special type of lignocellulose and lignification is presented by another of our staple industrial raw materials, viz., esparto grass. The grass is highly complex, both as a structure and an assemblage of products. The following results of later investigations have their obvious and direct technical value, and open up the

more scientific problems of constitution in specific terms.

These investigations have been carried out by our friend J. F. Briggs, and we are indebted to him for the communication of results.

Spanish Esparto was heavily crushed between steel rollers to open up the tissues to penetration by liquids. Boiled in water there is a progressive "extraction" of water-soluble products; in 2 to 4 hours, 8·4–10·9 per cent. calculated to dry substance.

Following this treatment, digestion in 1 per cent. NaOH for forty-eight hours in the cold, removed a further 25·8 per cent.

Determination of lignone by the phloroglucinol-absorption method (Cross and Briggs):—

	Per cent.	
On original grass gave	6·75	$C_6H_3(OH)_3$ absorbed in combination with lignone
Water-extracted grass gave	5·36	
Water and Soda-extracted grass gave	4·02	

The lignone components of the grass are, in part, much more sensitive to attack than in the case of the typical jute; applying the generally adopted specific treatment, viz., with 72 per cent. H_2SO_4 for isolating the lignone, the water-extracted grass yielded (*a*) 18 per cent., (*b*) 18·6 per cent.

Sfax Grass treated comparatively gave the following results:—

Soluble, three hours boiling with water	13·25 per cent.
Phloroglucinol absorbed by water-extracted grass	9·5 ,, ,,
Lignone residue (H_2SO_4 process)	26·5 ,, ,,

Further observations in development of the above tend to the general conclusions:—

In alkali "extracts" of the grass the lignone is in union with a carbo-hydrate colloid. The union of these is readily resolved on boiling the alkaline extract. Much of the lignification of the grass is a definite incrustation, *i.e.*, external to the fibres proper, the reactions of which are those of cellulose.

The esparto grass, though highly lignified, as shown by the phloroglucinol constants, is resolved to cellulose and soluble derivatives of non-celluloses, under the condition of the industrial treatments which are less severe than those required for the woods. The above observations give the rationale of differentiated treatment, not only for these extreme cases, but also for the varying grades of the esparto grass in ordinary paper mill practice.

From the by-product liquors of treatment of the grass in our paper mills, the lignone and colloidal carbohydrates are separated and isolated in the laboratory by a first treatment with 1·4 vol. 90 per cent. alcohol.

The lignone as lignic acid (soda salt), is soluble in the resulting dilute alcohol, and is obtained from the mother liquor, after removing the alcohol, by acid precipitation. The carbohydrate is washed with alcohol of the same dilution, and is obtained as a colourless body, retaining some soda (1·0 per cent. NaOH). This may be eliminated by further purification. The carbohydrate gives the high yields of furfural (40 to 45 per cent.) characteristic of the pentosanes. The proportions of these specific bodies recovered by the process are:—

	Spanish. Per cent.	Sfax. Per cent.	
Carbohydrate	9·0	10·0	Calculated to the original dry grass.
Lignic acid	12·0	15·0	

The lignic acids have the soda equivalent $100 = 7{\cdot}4\ Na_2O$.

It appears from these investigations that the lignone components of the grass tissues are a mixture of compounds conforming with the general type, differentiated or graduated in respect of resistance to hydrolysis.

It is clear that an exhaustive study of esparto as a chemical-biological subject or object would throw much light on the mode of elaboration of lignone, and the function of this group of unsaturated hydrobenzene derivatives in the plant.

Such investigations are much facilitated by the availability of raw material, and by-products of treatment, in indefinite quantity. This is generally true of the raw materials of our massive industries. It is further obvious that such materials have passed into industry, as staple products, on the basis of a "selection" from a large number of types which were *a priori* possible competitors.

Survival justifies the selection, and the student is well advised on these comprehensive grounds to give preference to such selected and established natural products as subject matter for research. There is always, moreover, with such products, the prospect or certainty of contributing something to technical progress.

In conclusion, we mention a type of water-soluble colloidal lignone complex, which characterises certain fruits, and notably the white currant, from which it was first isolated for investigation by Tollens (de Haas and Tollens, Annalen, 286 (1895) 278), and later, was further investigated to establish its identity as a com-

plex of unsaturated lignone groups, and saturated carbo-hydrate groups of the "pectic" type (C. F. Cross, Berl., Ber., 28 (1895), 2609).

On the general constitutional relations of the "Pectic" carbo-hydrates and the importance of these plant-tissue constituents, mention must be made of recent researches by F. Ehrlich (Chem. Ztg. 41 (1917), 197).

In physical properties the perennial woods certainly appear to be far removed from a fruit-colloid; but the divergence is only in external characteristics, and in the types selected for this *exposé*, there is an evident gradation.

Actually, wood substance proper is capable of re-hydration under the mechanical action of a paper-maker's beater; a fibrous wood-pulp being converted into a gelatinous mass, which dries to a coherent solid. The extreme divergence of a dense wood from a fruit-colloid as forms of matter is therefore only one of external characteristics.

This brief review of an aspect of a profoundly important chapter of natural history, should impress our "latter day" students of biochemistry that their world is very young and fresh, and that the investigations of the past fifty years, while laying out the lines of proximate progress, have exhausted no section of the subject.

THE ECONOMIC CONDITION OF EUROPE AFTER THE GREAT WARS OF A CENTURY AGO.*

In 1815 France had been engaged in almost continuous wars for twenty-three, England for twenty-two, years. The German States had been at war less continuously; but they had been fought over, conquered, and occupied by the French. Prussia, for instance, was overthrown in 1806. When the final struggle against Napoleon began, in 1812, there was a French army of occupation of nearly 150,000 men in Prussia alone. From 1806 to 1814 Napoleon's attempt to exclude English trade from the Continent had led to the English blockade—with its striking resemblances to, and its striking differences from, the blockade of 1914-19. Warfare was less horribly intense, and so less economically destructive, than it has become in our day; but what it lacked in intensity it made up in duration.

Take, for instance, the loss of life. For England it was relatively small—because for us the wars were never people's wars. In France also it was relatively small in the earlier years, when armies of the old size were mainly employed. But under Napoleon it became enormous. Exact figures do not exist, but French statisticians are disposed to place the losses in the ten years that ended with Waterloo at fully 1,500,000. Some place them higher. As the population of France grew about 40 per cent. between 1805-15 and 1904-14, this would correspond to a loss of, say, 2,100,000 on the population of 1914. The actual losses in 1914-18 are put at 1,370,000 killed and missing; and I believe these figures contain some colonial troops.

Or take the debts accumulated by victors and the requisitions or indemnities extorted from the vanquished. The wars of a century ago left the British debt at £848,000,000. According to our success or failure in securing repayment of loans made to Dominions and Allies, the Great War will have left us with a liability of from eight to nine times that amount. Whether our debt-carrying capacity is eight or nine times what it was a century ago may be doubted, and cannot be accurately determined. But it is not, I would venture to say, less than six or seven times what it was, and it might well be more. A good deal depends on future price levels. At least the burdens are comparable; and we understand better now where to look for broad shoulders to bear them.

After Waterloo, France was called upon to pay a war indemnity of only £28,000,000, to be divided among all the victors. With this figure Prussia was thoroughly dissatisfied. Not, I think, without some reason. She reckoned that Napoleon had squeezed out of her alone, between 1806 and 1812, more than twice as much—a tremendous exaction, for she was in those days a very poor land of squires and peasants, whose treasury only received a few millions a year. England, who was mainly responsible—and that for sound political reasons—for the low figure demanded of France, found herself, the victor, in the curious position of being far more heavily burdened with debt than France, who had lost. England, of course, had acquired much colonial territory; but on the purely financial side the comparison between her and France was most unequal. England's total national debt in 1817 was £848,000,000. France's debt did not reach £200,000,000 until 1830.

The reasons why France came out of the wars so well financially were four. *First*, she had gone bankrupt during the Revolution, and had wiped out most of her old debt. *Second*, under Napoleon she had made war pay for itself, as the case of Prussia shows. *Third*, there was no financial operation known to the world in 1815 by which England's war debt, or even half of it, could have been transferred to France. *Fourth*, England never suggested any such transference, or, so far as I know, ever even discussed it.

France's financial comfort, immediately after her defeat, extended to her currency. During the Revolution she had made a classical experiment in the mismanagement of credit documents, with the assignats issued on the security of confiscated Church property; but after that she had put her

* Extracted from the Presidential Address of Mr. J. H. Clapham, C.B.E., Litt.D., to the Section of Economic Science and Statistics, British Association, Cardiff.

currency in good order. Her final defeat in 1812-14, and again in 1815, did not seriously derange it. Indeed, the English currency was in worse order than the French, owing to the suspension of cash payments by the Bank of England; and so rapidly did France's credit recover after 1815 that in 1818 French 5 per cents. stood at almost exactly the present-day price of British 5 per cent. War Loan. That year she finished the payment of her war indemnity, and the last armies of occupation withdrew.

She had no doubt gained by waging war, and eventually suffering defeat, on foreign soil. No French city had been burnt like Moscow, stormed like Badajoz, or made the heart of a gigantic battle like Leipzig. Napoleon fought one brilliant defensive campaign on French soil, in the valleys of the Marne and the Seine, in 1814. In 1815 his fate was decided in Belgium. Hardly a shot was fired in France; hardly a French cornfield was trampled down. But France, as in 1918, was terribly short of men, and, again, as in 1918, her means of communication had suffered. Napoleon's magnificent roads—he was among the greatest of road engineers—had gone out of repair; his great canal works had been suspended. These things, however, were soon set right by the Government which followed him.

France's rapid recovery brings us to one of the essential differences between Western Europe a century ago and Western Eurcpe to-day. In spite of Paris and her other great towns, the France of 1915 was a rural country, a land of peasants and small farmers. Only about 10 per cent. of her population lived in towns of 10,000 inhabitants or more. The town below 10,000, in all countries, is more often a rural market town, utimately dependent on the prosperity of agriculture, than an industrial centre. Parallels for France's condition must be sought to-day in Eastern Europe—in Serbia or Russia. It is a condition which makes the economics of demobilisation easy. The young peasant goes back from the armies to relieve his father, his mother, and his sisters, who have kept the farm going. Moreover, France maintained a standing army of 240,000 men after 1815; and her losses in the Waterloo campaign had been so heavy that the actual numbers demobilised were relatively small. Demobilisation left hardly a ripple on the surface of her economic life.

The German states were far more rural in character even than France. There were a few industrial districts, of a sort, in the West and in Saxony; a few trading towns of some size, like Hamburg and Frankfurt; but there was nowhere a city comparable to Paris. In 1819 the twenty-five cities which were to become in our day the greatest of the modern German Empire had not 1,250,000 inhabitants among them. Paris alone at that time had about 700,000. German statesmen, when peace came, were occupied not with problems arising from the situation of the urban wage-earner, though such problems existed, but with how to emancipate the peasants from the condition of semi-servility, in which they had lived during the previous century. Here, too, demobilisation presented few of the problems familiar to us. Probably not one man in ten demobilised was a pure wage-earner. The rest had links with the soil. The land, neglected during the war, was crying out for labour, and every man had his place, even if it was a servile place, in rural society.

Things were different in England; but our demobilisation problem was smaller than that of our Continental allies or enemies, who had mobilised national armies, though not of the modern size. On the other hand, we had kept an immense fleet in commission, the crews of which were rapidly discharged. Early in 1817 Lord Castlereagh stated in Parliament that 300,000 soldiers and sailors had been discharged since the peace. In proportion to population, that would be equivalent, for the whole United Kingdom, to nearly 750,000 to-day. For these men no provision whatever was made. They were simply thrown on the labour market; and the vast majority of them were ex-wage-earners or potential wage-earners, industrial, mercantile, or agricultural. The United Kingdom was not urbanised as it is to-day; but the census of 1821 showed that 21 per cent. of the population lived in cities of 20,000 inhabitants and upwards, and probably about 27 per cent. (as compared with France's 10 per cent.) lived in places of 10,000 and upwards. As industry in various forms, especially coal-mining, spinning, and weaving, was extensively carried on in rural or semi-rural districts, it is certain that at least one demobilised man of working age in every three was a potential wage-earner of industry or commerce. And as Great Britain had lost most of her peasant-holders, whether owners or small working farmers, the remainder of the demobilised rank and file were nearly all of the argricultural labourer class. They had to find employment; there was not a place in rural society waiting for them, as there was for the average French or German peasant soldier. It is not surprising that the years from 1815 to 1820 were, both economically and politically, probably the most wretched, difficult, and dangerous in modern English history.

Things were at their worst in 1816-17, both for England and for her continental neighbours. Western Europe was very near starvation. Had the harvest of 1815 not been excellent, so providing a carry-over of corn, or had the harvest of 1817 been much below the average, there must have been widespread disaster; so thorough and universal was the harvest failure of 1816. In the latter part of 1815 (December) wheat fell in England to 55*s.* 7*d.*, although no grain imports were allowed, except of oats. Early in 1816 the United Kingdom was actually exporting a little wheat. Then came a terrible spring—a long frost; snow lying about Edinburgh in May; all the rivers of Western Europe in flood. An equally disastrous summer followed. There was dearth, in places amounting

to real famine, everywhere — worst of all in Germany. Unlike France, the German States of a century ago were extraordinarily ill-provided with roads. What roads there were had gone to pieces in the wars. In winter even the mails could hardly get through with sixteen and twenty horses. Food supplies could not be moved over long distances by land; and the slightly more favoured regions could not help the most unfortunate. There was a far wider gap between prices in Eastern and Western Germany in 1816 than there had been in the last bad famine year (1772). Each German State, in its anxiety, began to forbid export early in 1816, thus making things worse. At Frankfurt, the representatives of the German States, gathered for the Diet, could hardly feed their horses. Prices rose amazingly and quite irregularly, with the varying food conditions of the various provinces. In the spring of 1817 pallid half-starved people were wandering the fields, hunting for and grubbing up overlooked and rotten potatoes of the last year's crop.

In England the harvest failure of 1816 drove wheat up to 103*s.* 7*d.* a quarter for December of that year, and to 112*s.* 8*d.* for June of 1817. In Paris the June price in 1817 was equivalent to 122*s.* 5*d.* At Stuttgart the May price was equivalent to 138*s.* 7*d.* These are only samples. Think what these figures mean at a time when an English agricultural labourer's wage was about 9*s.* 6*d.*, and a French or German unskilled wage far less. It must be recalled that there were no special currency causes of high prices either in France or Germany. These were real dearth prices. In the spring of '17 the French Government was buying corn wherever it could find it—in England, North Africa, America—as another bad harvest was feared. Happily, the 1817 harvest was abundant, here and on the Continent. By September the Mark Lane price of wheat was 77*s.* 7*d.*, and the Paris price 71*s.* 9*d.*

I have gone into price details for the purpose of drawing a contrast between a century ago and to-day. Except for the damage done to the German roads, the wars had very little to do with these food troubles of 1816–17. High and fluctuating food prices were the natural consequence of the general economic position of Western Europe a century ago. It was only in the most comfortable age in all history—the late nineteenth and early twentieth centuries — that low and stable food prices came to be regarded as normal. In the eighteenth century, when England fed herself and often had an exportable surplus, fluctuations were incessant. Take the ten years 1750–1760. The mean price of wheat at Eton in '52 was 45 per cent. above the mean price in '50. The mean price in '57 was nearly 100 per cent. above the mean price of '50. On Lady Day '57 the price was 60*s.* 5¼*d.* On Lady Day '59 it was 37*s.* 4*d.* On Lady Day '61 it was 26*s.* 8*d.* The '61 mean price was exactly half the '57 mean price.

Eighteenth-century England was too well organised economically to be in much risk of actual famine, but for Ireland and large parts of the Continent famine was a normal risk. War and its effects had only accentuated, not created, that risk. Imports might reduce it, but could not avert it, because Western Europe tends to have approximately the same harvest conditions throughout, and it was impossible to draw really large supplementary supplies from anywhere else. So unimportant were overseas supplies that the Continent suffered very much more from the harvest failure of 1816, in time of peace, than from the eight years' English blockade in time of war. If overseas supplies could be got they were hard to distribute, owing to defective transport facilities. Thanks to the work of the nineteenth century, the most terrific of all wars was required to bring Western Europe face to face with what had been both a war-time and a peace-time risk a century earlier.

But the old Europe, if it had the defects, had also the elasticity of a rather primitive economic organism. Given a couple of good harvests, and a land of peasants soon recovers from war. Serbia had a good harvest last year (1919), and was at once in a state of comparative comfort, in spite of her years of suffering. A second good harvest this year, for which fortunately the prospects are favourable, would almost restore her. So it was with France and, to a less extent, Germany in 1816–18. In France acute distress in 1816–17 had been confined to the towns and to those country districts where the harvest failure was worst. The harvest of '17 put an end to it. One gets the impression that in Germany distress among the peasants themselves had been more widespread. Worse communications and the absence of a strong central Government seem to have been the chief causes of this, though perhaps the harvest failure was more complete. In France, as we have seen, the central Government took such action as was possible in the interests of the whole country. A parallel might be drawn between the German situation in 1815–17 and that of the States which have arisen from the break-up of the old Austro-Hungarian Empire since 1918. Freed from French domination, and then from the urgent necessity of co-operating against a common enemy, the German States relapsed into their ancient jealousies and conflicting economic policies, just as the new States, which were once subject to the Hapsburgs, have been forbidding exports of food and fuel and disputing with one another.

An excellent harvest in 1817 averted the risk of famine in Germany also; but anything that could be called prosperity was long delayed, whereas France was indisputably prosperous, judged by the standards of the day, and far more contented than England, by 1818-20. Germany had been so exhausted by the wars and incessant territorial changes of the Napoleonic age, and was politically so divided, that her economic life remained stagnant and her poverty great until at least 1830. It was all that the various governments could do to find money for the most essential of all economic measures—the repair and construction of roads—

whereas France had her splendid main roads in order again and had resumed work on her canals before 1820. But France had cut her losses nearly twenty years before, and had enjoyed continuous freedom from war on her own territory between 1794 and 1814, as we have seen. She had been well, if autocratically, governed, and her war indemnity was but a trifling burden. Her peasants were free and, as a class, vigorous and hopeful. She was united and conscious of her leadership in Europe, even through her ultimate defeats.

If the experience of Europe after Waterloo is, on the whole, of good augury for agricultural States, and especially for agricultural States with a competent central Government, for the industrialised modern world that experience is less encouraging. Great Britain alone was partially industrialised in 1815-20, and Great Britain, though victorious, suffered acutely. Mismanagement was largely responsible for her sufferings—mismanagement of, or rather complete indifference to, problems of demobilisation; mismanagement of taxes (the income tax was abandoned at the clamour of interested parties, and the interest on the huge debt paid mainly from indirect taxes, which bore heavily on the poor); mismanagement of food supplies, by the imposition of the Corn Law; and so on. But suffering due to international economic dislocation following war could not have been avoided by management, however good. The situation was unique. England alone of the European Powers had developed her manufactures to some extent on what we call modern lines. During the wars she had accumulated also great stores of colonial and American produce, which could only get into Europe with difficulty — by way of smuggling. In 1813, before Napoleon's first fall, her manufacturers and merchants were eagerly awaiting peace. In 1814 manufactures and colonial produce were rushed over, only to find that, much as Europe desired them, it could not pay the price. It had not enough to give in exchange; and England, being rigidly protectionist, was not always prepared to buy even what Europe had to give. There was no machinery for international buying credits. Merchants shipped at their own risks, usually as a venture, not against a firm order as to-day, and they had to bear their own losses—often up to 50 per cent. Continental economic historians have hardly yet forgiven us for this "dumping," which both drained away the precious metals to England—as there was not much else to pay with—and did a great deal of harm to the struggling young factory industries, which had begun to grow up under the protection of Napoleon's anti-English commercial policy.

THE OIL PALM IN NIGERIA.

The exploitation of the oil palm is still essentially a native industry in Nigeria, though, according to a note by the Comptroller of Customs at Lagos, published in the *Board of Trade Journal*, two European enterprises are now extracting oil within the country. The operations of one company have been so successful that they propose to extend their operations to new districts at an early date.

It is said that oil palms are actually planted by the native, but if so it is on a very small scale. What happens is that natural seedlings, of which millions grow and perish annually, are left "unweeded" when clearings are made for farms, and are thus able to survive owing to the diminished danger of being smothered by more vigorous weeds. Such seedlings as are thus accidentally protected are likewise accidentally cultivated, getting the benefit of the little cultivation given to the other crops on the farm. It is commonly stated by natives that oil palms on such farms are more prolific than bush palms, which is extremely probable. Growth and reproduction in wild palms is extremely slow, and whereas a deliberately cultivated palm begins to bear small bunches—of little value, it is true—at about the fifth or sixth year, it is not improbable that first fruiting is delayed ten or fifteen years in the bush, till the palms can get their heads exposed to free air and sunlight.

So far as is known, the oil palm is subject to no serious disease, but up country it suffers annually and severely by being swept by bush fires. It is not uncommon to see the oil-bearing bunches of fruits ablaze, and the whole crown severely scorched. Another serious menace is the tapping of the palms for toddy by the illicit method of stem (cabbage) incision, a method illegal amongst the people themselves, though now too frequently overlooked and left unpunished. Tapping the stem of the male inflorescence does little or no damage, though oil is lost by the cutting out of undeveloped fruiting bunches for the greater convenience of the tapper. Tapping is believed to be on the increase since the imposition of the heavy duties on imported spirits, but the evidence is not too conclusive. Further, it is, perhaps, and always has been, commoner in up-country districts, where the more economic exploitation of the palm for oil is not sufficiently profitable owing to the low prices for oil and kernels, which have to bear heavy transport charges to the coast. Wine-getting in such districts is a much more profitable business and less laborious than oil extraction, in consequence of which the only oil production of such places is for local consumption. A considerable quantity of kernels in such places are consumed in the native soap-making industry.

Need for Research.

Research is desirable on the keeping qualities of oils prepared in different ways. It is notorious that the pericarp oil which the native makes for his own consumption is of a better quality than what he takes to the European factory. It is more carefully prepared, and may be described as twice boiled. An extra boiling has often to be given at the buying factory—carried out by the seller—which, while it eliminates water, cannot affect the free acid content that has accumulated since the time of the

original preparation. The original extra careful straining and boiling carried out at the first preparation probably accounts for the superior quality of the oil which the native retains for his own consumption.

Need for Cheaper Machinery.

While the oil palm industry suffers like all others from insufficient and excessively expensive transport facilities, it has suffered most, perhaps, from a want of enterprise by the merchants in failing to put on the market cheap and sufficient nut-cracking machines, and perhaps, also, simple presses, but especially the former. This question is really one of great urgency with the discovery of new sources of vegetable oil in different tropical countries, and commercial development of the hydrogenation process which are now making low fish oils possible substitutes. Palm nut cracking by hand is laborious work, and serious competition of other oils might lead to a fall in price that would make local industry unprofitable. It has been said that a commercial use has been found for the shells, but no details have been published.

Copra.

The coconut palm, though abundant throughout the Southern Provinces—few villages being without some palms—has not been exploited for copra, except at one or two places on the coast. The climate up-country is admirably suited for copra production. The trees can stand the Harmattan, and the Harmattan could be used as a copra drier of the first order. The palms mature their main crop just about the time of the onset of the dry season. Nowhere is the coconut used as a source of toddy.

The only palm of economic importance—one which is indigenous to the country—is the wine palm (Raphia vinifera), which is a source of piassava fibre. Though the palm is extremely common, it has so far received little attention as a source of fibre.

Export of Palm Kernels, etc.

In 1919, 216,913 tons of palm kernels, valued at £4,947,995, were exported from Nigeria, compared with 205,167 tons, valued at £3,233,080, in 1918. Palm-oil exported weighed 100,967 and 86,425 tons in the same years, being valued at £4,245,893 in 1919, and £2,704,445 in 1918.

Ground-nut exports were 39,335 tons and 57,554 tons in 1919 and 1918 respectively, valued at £698,702 and £920,137.

Cola Nuts.

The Gold Coast variety of the cola nut can be successfully cultivated in many parts of the Southern Provinces. In some districts the farmers have found that it is even a more profitable crop to grow than cocoa. Each year about £200,000 worth of cola nuts is imported from the Gold Coast; efforts are, therefore, being made to encourage extensive cultivation of this crop. With this effort in view the Agricultural Department has, during the last two years, distributed about 73,000 cola seeds and 27,000 cola plants to farmers.

JAPANESE POTTERY INDUSTRY.

It is characteristic of Japanese ceramics that the numerous varieties have always been distinguished from one another geographically rather than technically. Thus Satsura ware, Imari ware, Awata ware, etc., names well known to foreign connoisseurs, refer to the districts in which the pottery is made. Indeed, the common Japanese word for pottery, "Seto-mono," is derived from the town of Seto, in Aichi-Ken, most famous of all for its wares, much as our word "China," is reminiscent of the country where the product originated.

Japanese wares may be classed roughly in three groups:—

1. Stoneware, including tiles and various utility objects, usually glazed and ornamented only by stamping or scoring, made in many parts of Japan and chiefly consumed locally.

2. Faience, such as Satsuma and Awata ware, most often with a crackle glaze, and highly decorated. It is not fired at so high a temperature as porcelain and is consequently softer and more fragile; but, for the same reason, more delicate colours may be used in decoration. Much of this sort of ware has found its way abroad under the designation of "curios."

3. Hard porcelain and semi-porcelain (Kutani among the coarser wares and Seto, Imari, and Kiyo midzu among the finer).

According to an interesting report on the Japanese pottery industry, by the United States Commercial Attaché at Tokio, the porcelain of Japan is made in a different way from that of China. Having been fashioned, it is baked in a biscuit state, then painted with such colours as require a great heat and the glaze applied, then burnt again at a much higher temperature; any further decoration in enamel colours or gilding is subsequently fired in a muffle kiln. These numerous firings are less tenacious than those used in China; hence Japanese specimens are frequently slightly out of shape.

The value of the porcelain and earthenware produced in Japan in 1918 was 44,214,084 yen (approximately £4,500,000). The relative production of the different classes of pottery for 1917 was as follows: Ornaments and art objects, 18 per cent.; dishes, 56 per cent.; industrial goods, 10 per cent.; toys, 5 per cent.; miscellaneous, 11 per cent.

In the years 1909-13 the value of the exports of pottery kept about the same figure, but from the beginning of the war the annual export steadily increased until the amount for 1918 had grown to nearly four times the figure for 1914. In the following table the total values of exports of pottery from Japan during 1913-18 are given.

	Yen.		Yen.
1913 . .	6,637,000	1916 . .	12,104,000
1914 . .	5,989,000	1917 . .	14,474,000
1915 . .	6,984,000	1918 . .	19,958,000

Yen = 2s. 0½d.

The following classes of porcelain and semi-porcelain products, which are produced in quantity, enter largely into the export trade, for which they are mainly manufactured: Tableware, including all the pieces comprised in ordinary dinner sets; sanitary ware, such as washbowls and other bathroom fixtures; electrical porcelain, such as insulators, sockets, etc.; and toys and novelties.

The earths used in the manufacture of commercial pottery may be divided into two general groups, technically known as kaolin and clay, the former being decomposed feldspathic matter contained in granite rock, and the latter being an alluvial deposit. Chemically they are similar, but physically they have different characteristics. In Japan is found a third variety, known as "rock clay" or "porcelain stone." This appears to be of similar construction to the kaolin, but decomposition has not gone to the extent of complete disintegration of the rock.

Kaolin for the potter's use is mined and washed in the same general manner in different parts of Japan. It is found in deposits in the high hills surrounding the town of Yamaguchi and is mined by tunnelling. The kaolin is loaded on small cars within the mine and run either to a dump at the mouth of the tunnel or directly to washing machines placed in buildings a few hundred yards distant. The kaolin is dumped on a platform and from there shovelled into a horizontal washing machine which consists of a barrel-shaped tub filled with water, about twelve feet long and six feet in diameter. Within this barrel is a revolving horizontal shaft to which arms are attached for the purpose of breaking up the mass.

The crude material as it comes from the mill consists of certain percentages of kaolin, quartz sand, and mica suspended in water. The particles are separated during the mixing process, and as they are discharged from the mixer the quartz, being heavier than the kaolin, is deposited in a vat or tank. The remaining kaolin and mica is then run through long troughs, which are divided into branches in order sufficiently to retard the flow of the mixture to permit the mica, which is lighter than the kaolin, to float off upon the surface of the water. The kaolin mixture is then run into large vats or tanks made of cement. The kaolin remains in suspension for a considerable time, but when sufficiently settled the surface water is drawn from the tanks and the residue pumped by hydraulic pumps into iron filter presses. As it leaves the presses the kaolin has the form of large circular cakes, similar in appearance to putty, which are placed on boards in open-air drying sheds or, in good weather, laid on racks exposed to the sun. When thoroughly dry these cakes are ready for market. In the Yamaguchi district the percentage of waste is extremely great, the actual amount of usable kaolin being only sixteen per cent. of the entire mass that comes from the mine.

The sand washings from this mass are used to a limited extent in the steel mills and in the manufacture of fire brick, but the great bulk is thrown on dumps unutilised.

The following analyses give an idea of the nature of the Japanese Kaolins and clays:—

Variety.	Percentage of—							
	SO_2.	Al.	Fe_2O.	Ca.	Mg.	K.	Na_2O.	H_2O.
Shiga-raki (Kyoto)	56·87	28·56	0·98	0·69	0·47	2·08	0·06	10·16
Owari (Seto)	54·65	32·35	—	0·90	0·37	3·27	2·22	6·30
Hizen (Arita)	49·25	38·89	1·14	0·15	0·36	2·01	0·39	5·90

Porcelain stone, which appears to be somewhat similar to our Cornwall stone, is believed to be produced by the action of solfataras upon volcanic rock (breccia). Great deposits are found in the Arita district, just north of Nagasaki. It is obtained from large quarries, and for local use is reduced chiefly by means of clumsy stamp mills run by water power, like those for milling rice. The material contains little or no mica; it consists of silicate of alumina in a physical condition between that of feldspar and kaolin, together with quartz sand, and is in itself capable of being made into chinaware without further admixture of other materials. Commercially, however, this is not practicable, because of the fact that the various percentages of ingredients are not uniform. It is also very susceptible to varying kiln temperatures, and has a limited range of fusibility.

The following table shows the analysis of various Japanese porcelain stones, as given by Rein, "Industries of Japan":—

Kind of Stone.	Percentage of—						
	SiO_2.	Al_2O_3.	FeO_3.	CaO.	KO.	Na_2O.	H_2O.
Arita stone I	78·70	14·27	1·16	0·45	2·24	—	3·29
Arita stone II	83·00	11·60	0·70	0·18	1·90	0·29	2·49
Amakusa stone	73·87	15·25	0·73	0·43	5·46	1·07	2·23
Kutani stone	76·60	14·75	0·86	0·29	3·91	0·65	2·68

All Japanese chinaware is made of one or more of the kaolins described above, but it has been found that English kaolin or china clay from Cornwall must be used to obtain the whitest and finest china.

Feldspar is found at the extreme northern and southern ends of the main island of Japan, but that from Fukushima is considered the best and gives the most satisfactory results. This is of excellent quality, and is delivered to the large pottery manufacturers in a crude state.

Saggars are fire-clay receptacles into which the ware is placed for burning. They are made of a crude fire-clay, the chief requirements being high refractory quality and great plasticity. The saggar clays of Japan are inferior to those found in America, the plasticity being below that required for the best results. As a consequence there is a much greater percentage of loss in firing; approximately forty per cent. of the saggars break in each firing. It is necessary to add some other material to counteract the excessive contraction of this clay under fire. In Japan, as elsewhere, the old cracked saggars are utilised for this, being broken up and coarsely ground to the size of a small pea as the maximum.

In the modern factories using the circular down-draft kilns a good quality of coal is required, which is difficult to secure in Japan. The coal used in the largest plant comes from Kyushu.

Plaster of Paris is perhaps one of the most important of the materials used indirectly in the manufacture of chinaware, since the moulds in which the ware is cast are composed entirely of it. It is manufactured locally, but its quality is such that for the best work imported material is used, and that is obtained from America.

The bulk of the decorating pigments and the finest colours come largely from England, formerly from Germany. The decalcomania sheets, which were formerly imported almost exclusively from Germany, are now coming principally from America. Some are being made in Japan, but it is likely that before long the domestic production will be displaced by the imported article. The costs are about three times the pre-war German price. Brushes are, of course, all of Japanese manufacture.

In the old-style Japanese potteries the glaze (called in Japanese "kusuri," a generic term for medicine) is compounded of carefully prepared clay paste mixed with wood ashes (usually oak and chestnut). The details of the mixture are usually held as trade secrets. In the modern factories the same sort of lead glaze is used as in Europe and America.

(To be continued.)

THE CARPET TRADE OF TIENTSIN.

It is only in recent years that Chinese carpets and rugs have been shipped abroad. At first only antique rugs were exported and eventually were all bought up. In 1912 American buyers on a visit to the Far East decided to send home small shipments of modern carpets. A demand for these carpets arose, which was accelerated in the early part of the war by the cutting off of the supply from Persia.

During the latter part of 1915 and early in 1916 such was the demand that prices rose until American buyers were paying at the rate of 2·75 to 3·50 Mexican dollars per square foot in Tientsin and Peking. As a consequence many new factories were started. The market in America became overstocked and prices dropped accordingly in China. Towards the end of 1916 and in 1917 it was possible to purchase good Chinese carpets of the 100-string quality at about 1·50 to 2 Mexican dollars per square foot. There was a large falling off in sales during 1917, which was partly due to the shortsightedness of the Chinese dealers and makers. The enormous demand from America experienced in 1916 tempted the weavers and dealers to endeavour to substitute an inferior article for the one stipulated. This was very soon detected by the buyers, and large quantities of the goods were thrown back upon their owners' hands, resulting in the closing down and ruin of many of the Chinese carpet dealing and weaving firms.

In the early part of 1918, principally on account of the American embargo, the local market prices dropped further until it was possible to purchase 100-string quality at about 1·20 Mexican dollars per square foot, and many factories were forced to close for lack of orders. In 1919, after the removal of the embargo, prices advanced. At present, writes the United States Consul-General at Tientsin, there are fewer factories than in 1916 and 1917, and consequently the production is much smaller. In fact, there have always been few actual factories. The manufacture is mostly a cottage industry and the work is carried on in the homes, where the families are often assisted by paid workmen. There are about as many factories in Tientsin as in Peking, though the best factory is in the latter city.

Chinese carpets for the American trade are usually turned out in 100, 90, 80, and 70 string qualities. At present Chinese vegetable dyes are used chiefly, owing to the high cost of the imported product. Heretofore imported dyes were preferred, as they were easier to work, and could be depended upon to give uniform results. In the Chinese dyes for the most part the colour lasts well, but it is very difficult to match colours and shades. Moreover the percentage used in mixing batches of dyes varies so much, the strength of the dye-stuffs being uncertain, that it is difficult to get the same colour twice in succession.

As regards designs, in cases of carpets and rugs made to order, the manufacturers can supply them or they can be furnished by the buyer from abroad. New designs are desirable, and it is a good plan for the buyer to furnish his own designs.

GROWTH OF CO-OPERATIVE DAIRYING IN NEW ZEALAND.

Perhaps no other country has witnessed so rapid and so great a development in the output of dairy products as New Zealand, or has seen such a wonderful advance in the scientific and mechanical details of manufacture. New Zealand has probably the largest and best equipped butter and cheese factories in the world, and its dairy farmers use separators and milking machines to a greater extent than elsewhere.

It is not only in mechanical and scientific development and the magnitude of its dairying output that New Zealanders have shown their energy and ability; in co-operative and financial organisation also they have achieved great results. The old privately-owned butter and cheese factories have almost universally given way to the co-operative business, in which the milk suppliers are the chief and, in most cases, the only shareholders. These associations are conducted, of course, entirely in the interests of dairy farmers. Some of the companies purchase fertilisers, implements, machinery, and other goods for their members, and even advance money for stock machinery, etc. They provide instructors who advise new farmers in the ways of handling dairy cows, growing fodder crops, and, of course, in the ways of increasing and improving milk production.

Of late years, writes the United States Vice-Consul at Auckland, there has been a tendency for individual factories to co-operate and even for co-operative associations to amalgamate. Striking instances of this development have taken place in the Auckland Province, where the dairying industry has expanded remarkably. The New Zealand Dairy Association was formed from a private company in 1901. Prior to its flotation as a co-operative company its output of butter was 1,200 tons per year. Under the new arrangement it soon became a very large concern, having 3,500 milk suppliers and manufacturing 6,000 tons of butter and 1,000 tons of cheese a year, whilst its annual sales amounted in value to nearly £1,460,000. Recently this association amalgamated with the Waikato Co-operative Dairy Co., which latter concern began in 1909-10 with an output of 150 tons of butter and a turnover of £14,600; in 1913-14 its output was 1,100 tons of butter and the turnover about £120,000; in 1918-19 its output was 1,000 tons of butter and 2,250 tons of cheese and the turnover £584,000.

The new amalgamation is known as the New Zealand Co-operative Dairy Co. (Ltd.), and is said to be the largest co-operative company of its kind in the world. The new company will have 5,000 suppliers, and will receive the product of about 100,000 cows. It has eight butter factories, ten cheese factories, and a large number of creameries. The output of butter this season is estimated at 8,500 tons, of cheese, 2,500 tons, dried milk, 2,000 tons, and casein, 300 tons, whilst the value of the turnover will approximate £2,400,000.

CORRESPONDENCE.

COLLOIDAL FUELS.

With reference to the recent discussion on the above subject in the *Journal* of August 13th and 27th, I should like to add a few remarks.

Colloidal fuel is a mixture of coal in a pulverised form and a petroleum residuum, such as is left after the extraction of the lighter and more valuable products.

The application of colloidal fuel is a development of the use of "straight" pulverised coal, for which it is already claimed that a more economical use of the total available heat energy in the coal is possible. Pulverised coal has been used commercially, and in the United States alone eight million tons of pulverised coal were manufactured in 1918.

Mixing oil and coal has the object of combining the advantages of both fuels, and with the mixture in a fluid state, the handling during transportation, distribution and storing on one hand, and the burning in the boiler, furnace, or stove on the other, present no technical difficulties.

Owing to the higher degree of combustion, the handling and labour charges, incidental to the removal of ash and clinker, are negligible. The stand-by losses are equally small owing to the ease with which steam can be raised, and its pressure controlled, in the case of a boiler, and any desirable temperature readily attained and maintained in the furnace.

Again, the higher heating value gives a more favourable fuel consumption, which reacts on the size of the storage tanks of the plant. The deterioration of coal, which is common with prolonged storage, is prevented; the danger of explosion when handling pulverised coal only is eliminated; the utilisation of huge quantities of "waste" coal, which so far only find limited application in the manufacture of briquet, is made possible.

On the other hand, however, there are difficulties which must not be lost sight of.

Coal must be crushed to a certain degree of fineness, and during that process the fuel passes through magnetic separators, drying plants (kept at a specific temperature), vertical or horizontal pulverisers (the degree of pulverisation depends on the number of operations and the method of mixing), and must be kept in specially designed stores until required for mixing.

The power required for crushing each ton of coal is about fifteen to twenty horse-power hours, and the cost varies according to output, the cost per ton in a 1,000-ton plant being only about one-fifth of that in a 5-ton plant.

Again, after pulverising the coal must be mixed with the oil, the cost being again proportional to the output.

As regards the actual mixer, it is obvious that the permissible percentage of coal will depend on the grade of the residuum. To-day, large quantities

of heavy fuels are available which, however, are very viscous. If the suggested ratio of 50 per cent. coal and 50 per cent. oil is applied in these cases, the practical difficulty of handling the mixture will arise.

From a commercial point of view, a mixture possesses an economic flexibility. As prices of the various constituents fluctuate, so their percentages are adjusted. As mentioned above, there are certain technical difficulties which will, therefore, govern the price of colloidal fuels.

Again, the cost of crushing and mixing affect the selling price, and the large consumer who can buy in the open market the requisite amounts of coal and oil at an economical figure, and then prepare this mixture in his own plant, is certainly at a very great advantage. The moderate and small consumer is in a less favourable position, and will have to pay such prices as are fixed by the colloidal fuel producer.

Colloidal fuel is quite suitable for power generating stations, industrial furnaces, railways, and, in fact, most stationary plants where the generation of heat is desirable.

Its suitability for marine oil-fired installations depends on a suitable grading of the mixture, if the modern practice of carrying the bunker in the double bottoms is to be adopted. Otherwise technical difficulties will arise, and the additional expenditure incurred in the alterations on board ship will make the scheme an unattractive proposition.

For internal-combustion engines, colloidal fuel as a commercial commodity is of no interest to-day.

J. L. CHALONER.

OBITUARY.

SIR LINDSAY WOOD, BT., M.INST.C.E.—The death occurred on the 22nd inst., at Chester-le-Street, of Sir Lindsay Wood, at the age of eighty-six.

Born at Killingworth Hall in 1834, he was educated at the Royal Kepier Grammar School, Houghton-le-Spring, and King's College, London. After serving his apprenticeship as a mining engineer at the Hetton Collieries, of which his father was then manager, he was appointed viewer at North Hetton Colliery, and subsequently became assistant manager to his father, on whose death in 1866, he was made managing director of the Hetton Collieries. He was also managing partner of the North Hetton Coal Company and managing director of the Harton Coal Company, and was on the board of John Bowes and Partners, the Netherton Coal Company, the Newcastle Electric Supply Company, the Durham Collieries Electric Supply Company, the Hendon Paper Works, and the North-Eastern Railway Company. He was mining engineer to the Ecclesiastical Commissioners and to the Greenwich Hospital. He rendered useful service on various Royal Commissions, among them that on Accidents in Mines, 1879–86, and that on Coal Supplies, 1903–5. He was president of the Northern Institute of Mining and Mechanical Engineers from 1875 to 1878. As president of the Durham Coalowners' Association, which post he occupied for over forty years, he won the confidence of the miners' leaders as well as of the coalowners. He was also chairman of the North of England United Coal Trade Association and of the Durham Colliery Owners' Mutual Protection Association. Before the passing of the Education Act of 1870 he had himself provided an efficient system of elementary schools in the neighbourhood of his own collieries, and his consideration for the well-being of those dependent on him showed itself in countless ways.

He was an active supporter of the Unionist cause, president of the party organisation in the Houghton-le-Spring Division, and chairman of the Durham County Division of the National Union of Conservative and Constitutional Associations. He was a Justice of the Peace and a Deputy-Lieutenant, and was sheriff in 1889. He was created a baronet in 1897.

He became a member of the Royal Society of Arts in 1882.

GENERAL NOTE.

THE WOLSELEY SHEFFIELD PLATE.—The late Dowager Viscountess Wolseley's collection of Sheffield plate, recently bequeathed to the Victoria and Albert Museum, is now exhibited in the East Hall. The collection occupies five large cases, and is remarkable both for the number of pieces and for their quality. It ranges over nearly the whole period of the art, from its earlier efforts, imitating the designs and even simulating the marks of solid silver in the rococo style of 1750-60, through the Adam classic manner of the latter half of the eighteenth century, to the heavier forms of the early years of the nineteenth century. The period of decadence, marked by the revival of an extravagant rococo, the last development of the industry before it was swept away by the invention of electro-plating about 1840, is alone practically unrepresented. As works of art the examples of the middle period, ranging in date from about 1770 to 1790, are the most pleasing. A few pieces of plating on brass are included in the collection as interesting examples of another method than the rolling together into one sheet of a layer of silver and a layer of copper, which constituted the old Sheffield process. By this important bequest the Museum is enabled to give an adequate representation of the growth and development of Sheffield plate, a truly national art invented by an English workman.

Journal of the Royal Society of Arts.

No. 3,541. VOL. LXVIII.

FRIDAY, OCTOBER 1, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

SPECIAL MEETING.

On FRIDAY, OCTOBER 15th, MR. THOMAS M. AINSCOUGH, O.B.E., His Majesty's Senior Trade Commissioner in India and Ceylon, will read a paper on "British Trade with India."

The chair will be taken at 4.30 p.m. by SIR CHARLES C. MCLEOD.

INCREASE OF SUBSCRIPTION.

At the Annual General Meeting, held on June 30th, it was unanimously resolved that the annual subscription of Fellows be increased from £2 2*s*. to £3 3*s*., and the Life Composition fee from £21 to £31 10*s*. The new scale will apply to all subscriptions due on and after Michaelmas, 1920.

These changes have been necessitated mainly by the great increase in the cost of the *Journal*, which rose from £1,767 4*s*. 11*d*. in 1913-14 (the last year before the war) to £2,851 11*s*. 10*d*. in 1919, and will probably rise further to about £3,800 for the current year. The general costs of maintenance and of conducting the work of the Society have also inevitably risen. Further particulars as to the financial position of the Society were published in the report of the Annual General Meeting in the *Journal* of July 2nd.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

RECENT RESEARCH IN CELLULOSE INDUSTRY.

By CHARLES FREDERICK CROSS, B.Sc., F.R.S.

Lecture II.—Delivered February 23rd, 1920.

CELLULOSE INDUSTRIES.

The cellulose industries fall naturally into three groups :—

(*a*) Manufactures which are based on the vegetable fibres, or more massive products of plant growths ; and which make use of and develop the external properties of these products.

(*b*) Manufactures based on the properties of these products as chemical individuals, more especially the chemical properties of their main constituent, cellulose.

(*c*) Industrial processes of resolution to ultimate products of value.

In the typical cases to be discussed in the present essay it is impossible to observe the sequence of this classification : the industries overlap, and it is a feature of their progress that they tend to overlap more and more.

From obvious causes the staple industries of group (*a*) are a growth rather than a creation : whereas in (*b*) and (*c*) a particular discovery, *e.g.*, of a reaction or a synthetical derivative of cellulose, may create or initiate an industry.

As a result of experience under the stress of war conditions there is a general recognition of the exceptional importance of the cellulose industries : they are not only key-industries, they are in the primary sense conditional of our existence as a civilised nation.

There is no need to insist upon what is now articulately recognised. Nor is it in the scope of these lectures to develop any theme, general or sectional, in detail.

The present purpose is an impressionist survey which will indicate lines of progress, technical and scientific, and the prefatory reference to the grouping of the cellulose industries is merely by way of suggesting a question of some importance : is there a sufficiently homogeneous science (including technology) of cellulose to justify the education and training of the cellulose expert; or is it to be presumed that a training in science is the full equipment, and that the technology of cellulose, incidental to and illustrative of general knowledge, may be left to the science-trained student to acquire incidentally ?

If this is to be taken into consideration as a formal problem, it may be of use to set out the range of industries involved :—

(*a*) Textile and paper-making, and auxiliary chemical industries.

Applications of straw and wood plait in hat industries ; timber and wood working.

(*b*) Nitro cellulose explosives, celluloid, film or sheet, and massive solids.

Cellulose acetate, varnishes (dopes), films, solids, and artificial textile fibres.

Mercerisation (lustre finish) of cotton textiles; parchmentising (cellulose papers).

Viscose manufactures, mainly "artificial silk" and threads (crin) and film (cellophane).

Cuprammonium solutions and applications to artificial silks and waterproofed textiles, papers and boards; zinc chloride solutions ; applications to manufactures of insulating materials.

(*c*) Wood distillation; oxalic acid manufacture ; cellulose fermentations.

In all these industries, the knowledge of the cellulose specialist is involved : problems are referred to him, and he is expected to have a general knowledge of the routine of practice and processes in the conduct of which most of these technical problems arise.

On this view, the supply of the raw materials is assumed; but their production involves the industries of agriculture and forestry. The cellulose specialist cannot ignore the essential perspective of his subject as a section of the natural history : and he has to deal with practical problems which arise in this connection, *i.e.*, the growth and preparation of these raw materials of industry.

This is an obviously formidable range of practical, wealth-producing activities ; and if experience is a necessary qualification for the career of the cellulose specialist, it appears to impose a very extensive training beyond the academic grasp of primary subjects.

For the guidance, and perhaps encouragement of any who may be attracted to this career, particular experience points rather to a training in science and the fundamental subjects of biology, chemistry, and physics, as the full primary equipment. Thereafter there should be some working experience in the textile and paper-making industries.

Technical work and experience is, for obvious reasons, of much less value as general education: it is obvious that the trained mind can easily assimilate technology, and with intelligence as well as intellect, the science-trained man is the best for the position of directive authority. The converse is generally, and quite wrongly, assumed in this country. And this is the cause of our having abdicated leadership of technical and industrial progress and development.

In the competitive era on which we have entered, we may either rely, as heretofore, on the spontaneous generation of the right men, with the right mind and morals to assure leadership, or at least the success of holding our own in cellulose matters : or we may adopt a deliberate constructive policy, and leave to chance only those elusive elements of personal equipment, which belong to imagination and take expression in enthusiasm.

Next to the provision of men, of workers, comes the important question of raw materials. It is a somewhat disturbing reflection that we depend in large part upon the outside world for our staple supplies. This absence of "control" has its consequences, and these no doubt are weighed and calculated by our politicians, in relation to the problems of international equilibrium.

On the broader view of men and nations, it is a feature of our natural history that the civilised life of mankind is dependent upon cellulose, and, in fact, largely dominated by cotton, whether taken as a massive product or considered as the minute entity, the ultimate individual cotton hair. It is also a feature of our most important staples, cotton and flax, that their economic production involves, in addition to the textile fibre, the simultaneous production of our two most important oil-seeds.

As a comment on the economic history of mankind, it is to be noted that up to the year 1860 the cotton seed was a waste product, even to the point that its destruction was the subject of compulsory legislation in the United States, to prevent insanitary accumulations in the cotton area.

The present production in the United States is some 6,000,000 tons per annum, requiring 850 mills as the equipment for converting to cotton oil and cake. It would appear that the cotton crop at least in the United States is fully utilised. The industrial position of the flax crops of the world is similar to that of the cotton crops of fifty years ago, but conversely as to the incidence of the waste : it is the flax straw, with its potential 15–20 per cent. fibre, which is destroyed, the portion of the flax crop which furnishes the textile flax of the world is only a fraction.

The above, however, is only a superficial and

general survey; for the cotton crop is still subject to prominent waste of harvested material, in the form of the short fibre remaining attached to the seed after the removal of the long staple textile cotton. This waste, however, has been taken in hand by a number of industrial technologists, and through their labours it is being brought within visible distance of full utilisation. Cotton hull fibre, as an industrial realisation, furnishing a new staple raw material for paper-making, and for the industries based on the synthetical derivatives of cellulose, is a peculiarly interesting chapter of industrial evolution.

It has been fully dealt with in recent technical literature (E. de Segundo, *R.S.A. Journal* and J. Soc. Chem. Ind., 1918), and therefore requires only this mention, with the fact that the bleached "hull" fibre is now on offer to the paper trade on such terms as lead to the conclusion that this colossal waste will be in due time integrally converted to use. The potential supply was estimated by Beadle and Stevens (J. Soc. Chem. Ind., 1909) at 120,000 tons per annum.

This marks a definite stage in progressive industrial economy, but to achieve the quantitative realisation of commercial values potential in harvested cotton, does not imply any advance in science: it was possible in 1860. There are, however, other values, and to explore these the researches required are of the purely scientific order.

In this perspective, the values which dominate industry are of the ultimate order, the qualities and properties (1) of the individual cotton fibres, (2) of the cotton substance as an assemblage of products, *i.e.*, of cotton, cellulose and non-cellulose.

In (1) are comprised (*a*) the factors of production of cotton, biological and agricultural; (*b*) the factors of the spinning processes.

This aspect of the subject has been dealt with by Dr. Lawrence Balls in a recent lecture, under the modest title, "Some Applications of Research to the Cotton Industry," *R.S.A. Journal.* It is unnecessary to traverse this weighty contribution to progressive science. With a sketch of the author's cultural researches, and reference to his more exhaustive publications, the student is furnished with full initiation into a fascinating study of natural history, and the attention of practical men is arrested by the opening dictum: "The whole technique of the cotton manufactures—our largest export industry—is based upon the properties of single unicellular seed hairs."

The link between the science of the biologist, and the exact knowledge of the scientific spinner, is through the expert valuer or grader of commercial cottons. Dr. Balls' analysis of the technique of evaluation, personal and impersonal, is of particular critical interest and value, and his investigations led to the invention of his grading machine—demonstrated and described—by which a sample of commercial cotton can be rapidly and accurately sorted and laid out in differentiated lengths (staple).

Now, to the practical mind it might appear that spinning quality is a direct and simple function of fibre length, and that the machine might take the place of the person (grader). But the inventor had no such expectation. It was clear to him that while the grader handles his sample with special manipulation to measure "staple," and apparently main attention to fibre length, there is a less conscious process of evaluation of other properties—qualities of substance and associated factors of integral "spinning quality."

There is a parallel case of expert evaluation in another cellulose industry which may be cited, perhaps by way of consolation to the "expert" in an age of mechanical inventions which menace his position.

The papermaker, the paper buyer, always engaged in a rapid comparative valuation of papers, has a particular basis of estimate, demonstrated by the comprehensive term "handle." Certain of the factors of the handle are accurately measureable, and so far, therefore, a comparative valuation is possible to a person, without the special qualifications of the expert. Another instance is the judgment of value in the case of textile goods, in which questions of "finish" are sometimes deciding factors.

These all illustrate an important general characteristic of the cellulose industries—a highly specialised, and in many respects, scientific development, but based on empiricism and experience, and therefore still awaiting the development calculated to follow from the application of scientific method as formally defined and understood.

In the case specially under consideration, the biologist enters the field; in logically developing the basis of investigation, and requiring accurate analyses of cottons in terms of fibre length, he invents a mechanical grader. This invention, however, is only incidental to a laboratory

investigation of spinning quality, Dr. Balls having passed by logical transition to the field of cotton spinning, as Director of the Research Laboratory of our Fine Spinners' and Doublers' Association (Manchester).

It is not for us to anticipate the publication of his research work in this field. It is evident that an industry which produces a cotton yarn of length-weight, *e.g.*, 200 miles to the 1 lb., must have arrived at a highly organised technique. It is generally known that this advanced technique is not based upon the order of control represented by measurements of dimensions and qualities of the ultimate cotton hair, but it is *a priori* clear that such is the present objective of the directors of the Association, and of Dr. Balls' research work.

In these terms the factors of spinning quality are :—

(*a*) Length and diameter of fibre, and other details of structural form, including the number of convolutions per (multiple) unit of fibre length.

(*b*) The composition of the fibre substance as a complex of chemical products, cellulose, and a group of "non-cellulose" components, cuto-cellulose, wax, pectic carbo-hydrates, and colloidal proteids ; last, but by no means least in importance, the variable water component, "hygroscopic moisture," of the complex, variable directly with the variations of humidity of the atmosphere.

The obvious practical measure of spinning quality is the highest technical-commercial value realisable from a given grade of cotton ; and the more obvious factors of value are the fineness, *i.e.*, maximum length-weight, strength (including elasticity), and uniformity of the yarn. Commercial values of yarns are certainly standardised up to a point in terms of these values, but the limitations of their applications are recognised.

As an illustration, it appears a simple mechanical operation to measure the strength (breaking strain) and "elasticity" (extension under breaking strain) of the yarn. But from the scientific or actual point of view the rupture of a yarn is a very complex physical effect. It is a simple operation to "blow out" a lighted candle ; but the extinction of the flame involves several physical-chemical factors.

It is sufficient for the present purpose to indicate in this superficial critical forecast, what is involved in the organised tasks of applying exact science to a highly-developed technical industry, necessarily embodying the accumulated results of experience, and exact practice, that is of highly scientific empiricism.

As a critical illustration of the extension of the field of vision, and the judgment essentially characteristic of this new development, we must mention Dr. Balls' demonstration of the daily growth rings in the cell wall of cotton hairs (Proc. R.S., B. 90 (1919), 542–559).

Applying a reaction which developes a regulated re-hydration of the cotton substance, a limited viscose reaction (Cross and Bevan Pat. 126174—1918), it was found possible to "swell" the fibre without structural distortion, and multiplying the 40·50 fold increase of dimensions by optical analysis with a $\frac{1}{12}$th in. lens, the actual magnification reached 20,000.

For the exact histological technique of the research, however, the optimum range was found to be at 5,000–9,000 diameters. The scope of this research will be appreciated by students of exact science, in the terms of an important conclusion in the published paper:—the dimensions of the wall of the lint hair are such that the thickness of each of the twenty-five growth rings can only be, at most, 0·4 μ, much less than the wave length of sodium light. Also it will illustrate the linking up of chemistry and biology with the technics of a great manufacturing industry. Workers of this school require no further proof of progress ; the "practical" school, moreover, has reached the position of the open mind, and not only in the cotton industry, but in the other leading textile groups, based on their respective raw materials, flax (and hemp), and jute. These have now their research associations, and the problems to be attacked range from the cultural to those of the spinning and auxiliary industries, and, lastly, to the countless problems of the everyday use of the fabrics. Of these the cellulose specialist has practical experience as detached questions of difficulty, and often of damage.

But the re-investigation of the industries, to bring them under the control of exact science, is in each such case a comprehensive parallel with what has been sketched above in the case of cotton, which is the typical form of "cellulose," both as textile fibre and chemical individual, and is the main text of this brief survey.

In actual new developments, of developments of the newer textile industries, we may briefly notice two, and mainly by way of exhibition of fabrics which show the wide range of effects, beautiful and useful, which they cover.

At the one extreme is the artificial silk, and at the other the twisted paper yarn.

The war conditions of the period 1914–19 have specially affected these industries, arresting the expansion of the cellulose "silk," but greatly stimulating the growth of the latter. The world production of artificial silk is estimated at about fifty tons per day, and mainly by the "viscose" process. A new form of the product is the "staple fibre" of the (German) Vereinigte Glanzstoff A.G., and "fibro" of British manufacture, which is manipulated as a fibre of short length (4–5 cm.) and spun into yarns of a type intermediate between "spun silk" and wool. We may refer the reader for the latest technical information to a recent article in the Journal Soc. Chem. Ind., by L. P. Wilson, 39 (1920), B. 266.

The industry in (twisted) *paper yarns*, which had struggled to hold a competitive position under normal industrial conditions, was developed in Germany and Austria during the war to the astonishing production of 250,000 tons per annum, being applied as a substitute for the staple long-fibre textiles in the most varied directions.

The industry in this country is represented by the Textilite Engineering Company, 36–38, Queen Street, E.C. 4, who have considerably advanced the technique of production. This firm kindly supplied an extensive exhibit of great technical interest, and to them we may refer our readers for information in detail.

In conclusion of this textile section, we notice the "artificial silk" of the British Cellulose and Chemical Manufacturing Company, of London and Spondon.

This product is the acetic ester of cellulose, drawn from solution to a lustrous thread in continuous length; the textile yarn being a multiple thread with sufficient twist for working on the loom or otherwise.

The manufacturing company kindly supplied an exhibit of the product which has an obvious scientific and technical interest. On the technical-industrial aspects of its competition with the cellulose silks, we refer the reader to the paper of L. P. Wilson (*loc. cit.*), and a later note by J. F. Briggs (*ibid.* B. 286).

It should be mentioned that the acetate silk has been manufactured for some time in the United States by the Lustrose Company, of Boston, developing the work of the distinguished group of cellulose specialists, A. D. Little, and his associates, Messrs. Miles and Mork. The Miles patent, 838,350, 1906, U.S.A., marked an important stage of technical progress. A clear exposé of the technical history of the acetate processes is given by E. C. Worden in Journal Soc. Chem. Ind., 38 (1919), 370.

There is a factor of value in cotton fabrics which requires mention, not only from its obvious importance, but because it is frequently left out of consideration; and, again, because it is a link between a number of cellulose industries in regard to technical progress. Cotton yarns are not measured in terms of specific volume, *i.e.*, apparent volume. In paper values, on the other hand, the specific volume or specific weight comes into practical consideration; but for a discussion of the technical bearings of this section of the subject, readers are referred to "Paper Making," Cross & Bevan Ed., 5, pp. 401–403.

In the case of artificial silk the question of "bulk" of the yarns arose, perhaps accidentally to become, at maximum bulk, a definite objective of the process. This apparent bulk evidently measures the covering power of the yarns in weaving. This quality finds a very striking illustration in the industrial application of another vegetable fibre, kapok, as the basis of appliances for life-saving in the sea services. These appliances came into prominence during the war, and investigations were required by the Boddy Company of the qualities of different grades of this fibre. Some results of these investigations are recorded in a paper in J. Soc. Dyers, col. 32 (1916).

The following results of further investigation may be mentioned.

In respect of volume occupied by a mass of the fibre under compression, it was found that, compressed by hand in a regular cylinder by means of a plunger, 1 gram of the fibre occupied volumes of 10·0–13·2 cc.: this is the measure of its quite exceptional floating power, and the efficiency of the appliances in question, as compared with appliances based on cork, with its volume (in mass) of 4·0–5·0 cc.

In investigating the relation of the fibre in the mass, and the individual seed hair to increased pressure, the following results were obtained—a comparison being made with cotton:—

	Vol. of 1 grm. compressed by hand.	Pressure to reduce vol. to one half.	Break down pressure.
Kapok .	10·0 cc.	3·8 atm.	100–120 atm.
Cotton .	3·6 ,,	7·5 ,,	720–840 ,,

In reporting these results, Mr. R. H. H. Stanger, who carried out the tests, called attention to the localisation of the breakdown —disintegration of the fibre—at the centre of

the compressed mass, and to the fact that in further investigations the air-factor would require special investigation.

The subject is mentioned here in reference to the practical question of compression of the fibre (kapok) to bales for transport.

The fibre-substance is recognised as being sensitive to frictional wear, losing volume in the mass, and having its special quality of resistance to wetting. This subject is only superficially touched by the above investigations, but opens out some fundamental technical points which have received but little attention.

The industries based on the properties of cellulose, as a chemical individual, are vast and diverse. The transformation of cellulose to artificial fibre has been noticed in regard to technical progress.

A brief mention is required of an industry which, for obvious reasons, grew rapidly to colossal proportions during the war. Cellulose nitrate, as the basis of modern "smokeless" explosives, was a *sine qua non* of the great war. On the technical aspects of "nitro-cellulose" manufacture, there are two secondary factors of quality which require mention: (1) The stability of the product; (2) the viscosity of its solutions in specific solvents.

In regard to (1) the recognition of sulphuric residues in combination as cellulose sulphuric esters (Cross, Bevan and Jenks, Berl. Ber. 34 (1901) 2496; Hake, J. Soc. Chem. Ind., 24, 374) has led to more definite control of the "stabilisation" treatments. But there are other causes of instability, additional to the primary property of a highly explosive compound. In this more complex question is involved that of raw material, *i.e.*, the basis of cellulose. This was a subject of investigation and correspondence in 1910–11, as between the writer and Mr. W. Rintoul of the Nobel's Explosives Co., on the special point of a "normal cellulose" and its definition. On general grounds a calico printer's "madder bleached" cloth appears to conform with such specification. Mr. Rintoul investigated a series of specimens, prepared by slightly varied treatments, and his figures for the systematic control tests confirmed this selection of the typical "normal" cotton cellulose:—

Solubility in 3 per cent. NaOH	1·66	per cent.
Copper reduction	0·39	,,
Ash	0·16	,,
Dyeing test . . .	Uniform, light, medium.	

Mr. Rintoul compared these figures with those of his records of tests of "hundreds of specimens of cellulose from various sources." Of such the one exceptional best gave:—

Solubility in 3 per cent. NaOH	2·36	per cent.
Copper reduction	0·42	,,
Ash	0·69	,,
Ether (soluble)	0·64	,,

Mr. Rintoul's industrial experience would, no doubt, be mainly with "waste cottons" of all kinds; the scientific investigations of the Nobel Co., on the other hand, necessarily traversed the wider field of first principles. Thus the writer has been associated with him in an investigation to determine the thermal constants of the primary ester reaction:—

$$C_{12}H_{20}O_{10} + 5\ HNO_3 = C_{12}H_{15}O_5(NO_3)_5 + 5\ H_2O.$$

The elaborate physical research work involved has been undertaken by Mr. Bousfield, F.R.S., and the results, which will be published in due course, necessarily involve close verification. This research is noted here as evidence of progress, but also of our lack of knowledge of fundamental things in the general chemistry of cellulose.

The question of "waste cottons"—as, up to a period, the exclusive raw material for this industry—has been elaborately re-investigated, under the exigency of war conditions, by Sir R. Robertson, F.R.S., and the technical chiefs of the Naval and Military Services. Their records must be a document of high scientific and technical interest, and we may hope in due time to be able to include it in the general history of the subject.

One section of the research, however, and perhaps the most important, is the subject of a paper by Dr. W. H. Gibson (Chem. Soc. J., May 1920, v. 117, p. 479). The author applies a *positive* criterion and control of "cellulose quality" in relation to the properties of the nitric esters, in terms of viscosity of solutions in a standardised cuprammonium. Beyond the contribution to technology, the paper opens out a number of directions of investigation of ultimate problems, and is therefore commended to students for close study. Specialists require no reminder of the suggestive character of the publication.

Dr. Gibson is chiefly concerned on the technical side with "cotton wastes." But the department has had to consider other problems in connection with supplies of raw materials. The data not being published, there is only "general knowledge" of the fact that, for special types of nitro-cellulose ammunition, it was found advantageous, and in fact necessary, to adopt

a prepared raw cotton, *i.e.*, in the advanced state of mechanical purification represented by a spinner's sliver. It is to be inferred from this, that the associated mechanical impurities of a raw cotton, are a definite cause of instability of the nitrate products; but perhaps also, an unmanufactured cotton permits direct control, in terms of invariable, or least variable viscosity, of the solubilised nitrates.

In concluding this section, there are two raw materials to be mentioned, as having become prominent during the war. The first of these is the short-fibre waste from American cotton seed, already mentioned on general grounds of industrial value.

This material was utilised on a very large scale in the United States for the production of "nitro-cellulose" explosives and ammunition.

The second is wood cellulose, to the use of which our enemy-friends were forced by the restriction of their cotton supplies. It was suggested, but only in our daily journals, which still reflect the public indifference to scientific-technical matters, that to cut off cotton supplies to the enemy countries would be to end the war, *ipso facto*. There is some support, it is true, for the general dictum, to be translated into the language of those more directly affected, "Ohne Baumwolle—kein Krieg"; and the experience of our own specialist departments, recorded above, is to be cited in illustration. But the facts are that wood-cellulose was used on the large scale in the production of nitro-cellulose powders.

Incidentally, this question of cotton cellulose in comparison with wood cellulose raises the deeper scientific problem of "normal cellulose," and directs attention to the natural paradox of a seed-hair of an annual plant representing the normal cellulose, *i.e.*, as prototype, whereas the wood cellulose of perennial forest trees occupies the inferior position in regard to chemical inertness or non-reactivity, which means stability.

It will be already evident to the reader how wide and apparently diversified is the range of subjects and interests connoted by the title of this lecture; that it has been necessary to treat the subject-matter discursively and suggestively rather than exhaustively; and that a still more condensed mention must suffice for the remaining matters—interesting by way of promise of technical progress.

The "limited viscose reaction" (Cross and Bevan, U.K. Patent 126,174, 1918) has been already noticed in connection with its major effect: the controlled hydration of the fibrous celluloses with increase of dimensions up to 20–60 diameters. The basis of the reaction (of hydration) is (1) treatment with caustic soda solution at 9–10 per cent. $NaOH$ in the cold, and squeezing so that the cellulose mass retains 2·33–2·66–3·0 times its weight of the lye; (2) afterwards exposing to carbon disulphide as in the well-known viscose reaction, but for longer periods.

Subsequent treatment with water removes the excess of $NaOH$, the fractional quantities of soluble xanthate (cellulose) and thio-carbonate by-products, but there is a disproportionate hydration effect, the degree of which is variable directly with the proportion of $NaOH$ (lye) to cellulose. The much swollen hydrated fibres form a gelatinous colloidal mass, but retain a certain quality of "free" working on a paper-maker's wire cloth, such that it can be worked up into sheets. According to the method of subsequent treatment for dehydrating the fibre, the cellulose "reverts" to its original state, the sheet or felted mass is soft and coherent only through the interlacing of the fibres; or the reversion is partial, with the result that the sheets have a parchment quality, coherent and semi-transparent.

This process opens out a general critical revision of the major preparation treatment of the paper-mill—the beating operation. In this operation several factors are involved, of which two are particularly brought under independent control (1) length of fibre, (2) degree of hydration of fibre substance. Not only in the paper-making process, but in finishing and dyeing treatments of cellulose textiles, a controlled hydration treatment opens out the investigation of new resultant effects. These investigations are in progress. There are, moreover, certain bearings of the results upon the ultimate problems of chemical constitution which remain to be discussed, and are deferred to the next lecture.

A certain parallelism with this completed range of effects of the xanthic reaction characterises the interaction of the cellulloses with solutions of the sulphocyanides. These reactions were observed and studied some years ago by A. Dubosc (Bull., Rouen, 1905), who claimed to obtain solutions of cellulose capable of competing in industrial application with the cuprammonium product and others.

The matter has been developed by our friend Mr. H. Williams, of the Manchester Oxide

Company, and the following note is kindly supplied by him :—

"The gap between 'viscose' and the solution of cellulose in concentrated aqueous zinc chloride, and other acid and salt solutions, has recently been bridged.

"The action of thiocyanide solutions on cellulose was first investigated by Dubosc (Bull. Soc. Ind. de Rouen, 1905, page 318), and more recently P. Weirnarn (D.R.P. 275,882, 1914) claims the solvent action of any neutral salt solution '—the term 'action' being used in its widest sense; but these results do not appear to have been industrially developed. The subject has, however, been independently revived (Manchester Oxide Company and H. Williams, E.P., 123,784 and 124,979) on the basis of a systematic study of the metallic thiocyanide solutions, with the result that the action of any given salt of the sulphocyanate group is specifically to be predicted in terms of definite constants, *i.e.*, viscosity, heat of solution, etc.

"These systematic researches will be published in due course. On the industrial side, the work has led to processes for the spinning of thread and the production of parchmentising and 'vulcanising' effects on paper, of special advantage."

The document above referred to, the specification D.R.P. 275,882 (1914) of P. Weirnarn, is a noteworthy contribution to the subject. The scope of the research and of the resulting industrial processes may be judged from the claim of the patent which we give below (translated) :—

"Process for the conversion of cellulose materials of all kinds into different kinds of plastic or gelatinous masses, or colloidal solutions, distinguished by the fact that the cellulose is acted upon by aqueous solutions of neutral salts (solutions of zinc salts, potassium and ammonium thiocyanates, potassium iodide and potassium or barium mercuric iodides excepted) under conditions of concentration, pressure, temperature, and time of action depending on the nature of the salt."

Cellulose Fermentation.—The literature of cellulose fermentations is extensive; the natural processes are incidental to agricultural observation and practice, and have been specifically studied in special cases, as, for instance, in connection with silage (O. Emmerling, Berl. Ber. 30, 1869, 1897).

More specific researches are those of MacFadyen and Miss Chick of the Lister Institute, who studied special groups of thermophilic bacteria, in relation to the breakdown of typical forms of cellulose which we prepared for investigation.

The later researches of Omelianski (Compt. Rend., 1897) were more specific as to the ultimate products.

All these laboratory processes of fermentation have, so far, involved lengthened periods for complete breakdown of the cellulose, and would be excluded on this account from consideration as industrial processes.

But recent advances in research in this direction have evolved a controlled industrial process for the fermentation of celluloses, both fibrous and cellular, giving rise to ultimate liquid products in good yield. The following note of its results and scope is kindly supplied by Mr. Langwell and the Power Gas Corporation, Ltd., who are developing the laboratory results on the scale of an industrial unit. The process may be so controlled as to yield at will, either acetic acid or alcohol as main product.

Such a resolution of cellulose will doubtless have a very profound influence on the supply of liquid fuels in the future, as the most diverse vegetable products, at present of only nominal value, will yield to fermentation, and produce alcohol or alternative products at such cost, and in such quantity, as to compete to advantage with existing fuels from mineral oils and coal.

The prospect of producing fuel alcohol by the present brewing and distilling practice is excluded by the fact that the raw materials required are staple foodstuffs, as well as the "natural" sources of starches and fermentable sugar, with a consequent prospective high-selling value.

The production of alcohol from calcium carbide is also prejudiced by the high cost of raw material.

The simplicity of procedure in these new cellulose fermentations makes them workable in the most diverse climates, and the troublesome sterilisation is not necessary, as it is in ordinary distilling practice.

It seems probable, therefore, that they will become a source of liquid fuels in the future, meeting the present need, and utilising material available in enormous quantities, without competing with any other industry. For example, the Nile Sudd deposit alone, which is 35,000 square miles in extent, and only *one* of the massive cellulose wastes, would if fermented produce 50 to 80,000 million gallons of alcohol, or alternative products, per annum, an amount more than sufficient to supply the whole world

with liquid fuel, and still leave some over for domestic lighting and heating purposes.

Considering the other massive cellulose wastes and their wide distribution, such a superabundance will eliminate the possibility of a rise in the cost of raw material.

FISHERY INVESTIGATION.*

The opening up of our north-western fishing grounds and banks is due to the scientific curiosity of Wyville Thomson and his *confrères* as to the existence or non-existence of animal life in the deep sea. It was sheer desire for knowledge that attracted a host of inquirers to investigate the life history of river eels. The wonder of a fish living in our shallowest pools and travelling two or three thousand miles to breed, very likely on the bottom in 2,000 fathoms, and subjected to pressures varying from 14 lbs. to 2 tons per square inch, is peculiarly attractive. It shows its results in regular eel farming, the catching and transplantation of the baby eels out of the Severn into suitable waters, which cannot, by the efforts of Nature alone, be sure of their regular supply. Purely scientific observations on the life histories of flat fish—these were largely stimulated by the scientific curiosity induced by the views of Lamarck and Darwin as to the causes underlying their anatomical development—and on the feeding value and nature of Thisted Bredning and the Dogger Bank, led to the successful experiments on transplantation of young plaice to these grounds and the extraordinary growth results obtained, particularly on the latter. Who can doubt that this "movement of herds" is one of the first results to be applied in the farming of the North Sea as soon as the conservation of our fish supply becomes a question of necessity?

The abundance of mackerel is connected with the movements of Atlantic water into the British Channel and the North Sea, movements depending on complex astronomical, chemical, and physical conditions. They are further related to the food of the mackerel, smaller animal life which dwells only in these Atlantic waters. These depend, as indeed do all animals, on that living matter which possesses chlorophyll for its nutrition and which we call plant. In this case the plants are spores of algae, diatoms, etc., and their abundance as food again depends on the amount of the light of the sun—the ultimate source, it might seem, of all life.

A method of ascertaining the age of fishes was sought purely to correlate age with growth in comparison with the growth of air-living vertebrates. This method was found in the rings of growth in the scales, and now the ascertaining of age-groups in herring shoals enables the Norwegian fishermen to know with certainty what possibilities and probabilities are before them in the forthcoming season. From the work on the blending together of Atlantic with Baltic and North Sea water off the Baltic Bight and the subsequent movements of this Bank water, as it is termed, into the Swedish fiords can be understood, year by year, the Swedish herring fishery. It is interesting that these fisheries have been further correlated with cycles of sun spots, and also with longer cycles of lunar changes.

The mass of seemingly unproductive scientific inquiries undertaken by the United States Bureau of Fisheries, thirty to fifty years ago, was the forerunner of their immense fish-hatching operations, whereby billions of fish eggs are stripped year by year, and the fresh waters of that country made into an important source for the supply of food. The study of the growth stages of lobsters and crabs has resulted in sane regulations to protect the egg-carrying females, and in some keeping up of the supply in spite of the enormously increased demand. Lastly, the study of free-swimming larval stages in mollusca, stimulated immensely by their similarity to larval stages in worms and starfishes, has given rise to the establishment of a successful pearl-shell farm at Dongonab, in the Red Sea, and of numerous fresh-water mussel fisheries in the southern rivers of the United States, to supply small shirt buttons.

Fishery investigation was not originally directed to a more ambitious end than giving a reasonable answer to a question of the wisdom or unwisdom of compulsorily restricting commercial fishing, but it was soon found that this answer could not be obtained without the aid of pure zoology. The spread of trawling—and particularly the introduction of steam trawling during the last century—gave rise to grave fears that the stock of fish in home waters might be very seriously depleted by the use of new methods. We first required to know the life histories of the various trawled fish, and Sars and others told us that the eggs of the vast majority of the European marine food species were pelagic; in other words, that they floated, and thus could not be destroyed, as had been alleged. Trawl fishing might have to be regulated all the same, for there might be an insufficient number of parents to keep up the stock. It was clearly necessary to know the habits, movements, and distribution of the fishes, for all were not, throughout their life, or at all seasons, found on the grounds it was practicable to fish. A North Sea plaice of 12 ins. in length, a quite moderate size, is usually five years old. The fact that of the female plaice captured in the White Sea, a virgin ground, the vast majority are mature, while less than half the plaice put upon our markets from certain parts of the southern North Sea in the years immediately before the war had ever spawned, is not only of great interest, but gives rise to grave fears as to the possibility of unrestricted fishing dangerously depleting the stock itself. There is, however, another group of ideas surrounding the question of

* Extracted from the Presidential Address of Professor J. Stanley Gardiner, M.A., F.R.S., to the Geological Section of the British Association, Cardiff.

getting the maximum amount of plaice-meat from the sea; it may be that the best size for catching is in reality below the smallest spawning size. I here merely emphasise that in the plaice we have an instance of an important food fish, whose capture it will probably be necessary to regulate, and that in determining how best the stock may be conserved, what sizes should receive partial protection, on what grounds fish congregate and why, and in all the many cognate questions which arise, answers to either can only be given by the aid of zoological science.

JAPANESE POTTERY INDUSTRY.

(*Continued from page* 718.)

The great bulk of chinaware produced in Japan is made by the old methods of manufacture and to a very considerable degree is a household or community industry. For example, in the Seto district one family will be found making the models and moulds. On the village streets one can see these moulds being carried by hand on boards to another household where they will be used for the forming of the ware. Cups and saucers are produced in large quantities in this district, one man being able to produce by casting 2,000 cups per day; but the quality is very poor. When the ware is ready for burning it is taken to the kiln. All tableware undergoes two fires, the first being a low degree of heat known as the "biscuit fire," which thoroughly dries and hardens the ware so that it can be handled with safety, and which also enables underglaze decorations to be applied. The ware that has gone through the "biscuit fire" is dipped in a glaze which is practically a liquid glass composed of feldspar, lead, clay, flint, and, in some cases, a frit composed of borax and flint.

The old type of Japanese kiln is unique. The kilns are built on the side of a hill in separate units, according to the requirements of the individual or the community. In some cases there is but one kiln, and it is built at the bottom of the hill. As the factory enlarges, another unit is added to the side of the first kiln and at a higher level, according to the incline of the hill. As the kilns increase in number they also become of larger dimensions. The kiln resembles in shape the inside of the ordinary muffle or decorating kiln in the United States. The floor is usually covered with sand, and the firing is not begun until all the kilns have been filled with ware. The fire is started in the kiln at the bottom of the hill, the heat entering from fire boxes which extend the entire width of the kiln near the boundary between the two arches. Each kiln has a draft hole half-way up the side, above the hole where the fire is fed. The direct brunt of the heat is taken by a fire-brick wall. The flame and heat, circulating about the rounded roof of the kiln, pass into the kiln next above through a series of openings on the level of the floor of that kiln. The heat passes from one kiln to the other, the surplus from one drying out and warming the contents in the following kiln. Wood is used entirely in firing the kilns and is delivered to the kiln burner in bundles, each stick being about the size of a man's wrist and about 15 inches in length. The kilns are fed from either side through a small hole less than one foot in diameter, the tender putting in a stick at a time, a continuous process. The steady demand for wood has stripped the adjacent countryside of forest and the cost of fuel is very high. Four bundles of wood, altogether about three cubic feet, cost 1 yen (2*s.* 0½*d.*), four times the pre-war price. The firing of each furnace costs about 500 yen (£50).

The heat is intense. As each kiln acquires the desired heat the feeding is discontinued, and the firemen proceed to the next kiln above, which has already acquired sufficient heat to ignite the wood. By the time the third kiln is fired the first one has cooled sufficiently to permit the ware to be taken from it. These kilns are a crude form of the German Hoffman kiln.

As the ware is taken from the kilns it is ready for the market or for the decorating shop, as the owner may elect. Wares produced by community kilns are usually marketed through merchants in the central village. In such a community potters of all degrees are to be found, from the individual making special articles and having them burned by the owner of the community kiln to the manufacturer who has his own shops and his own kiln or kilns.

The aggregate production of the numerous pottery villages in Japan amounts to a considerable figure, and much of it finds its way into the channels of foreign trade. Nevertheless, with the cost of living increasing in Japan by leaps and bounds and with labour expenses rising in proportion, the day is not far distant when the highly organised and efficiently conducted modern pottery, with its labour-saving machinery and quantity production, will supersede the cottage and community system. The Japanese have not been slow in appreciating this tendency. In Nagoya, the centre of the industry in Japan, a pottery has been built on the most modern lines. Upon entering a new factory one is at first struck with the fact that labour is still by no means considered the first and greatest factor in costs. Every ton of material is brought to the works by man power. There is no railway siding. All the materials, bulky as they are in the pottery industry, such as clay, feldspar, flint, wood and coal, are carted in small one-horse wagons, each horse being led by a man. Such materials as come in bulk are piled on the wagon in shallow tray-like baskets, each containing an amount convenient for a man to carry. The second thing particularly noticeable is the large amount of hand labour employed in the breaking up and sorting of the raw materials, and also the exceedingly minute care taken in removing any foreign matter from the broken mass.

Saggars, as explained above, are the fire-clay cases into which the ware is placed for burning. Setters are fire-clay discs, or very low saggars

capable of holding but one plate or dish. In the Nagoya factory the saggars and setters are made in saggar machines varying in size according to the article required. These machines consist of steel dies which squeeze the clay into the desired shape, the pressure being applied by a screw press.

The same method used in other countries for the making or forming of the wares is in vogue in this factory, namely, pressing, casting, hollow-ware jigging, flatware jigging, throwing, and turning. The casting process is more largely used than that of pressing.

The ware, when ready for the first fire, is taken to the second floor and placed in the upper chamber of the kiln. It is then piled on tiers of bats supported by heavy clay props, as is usually done in the decorating kilns in America. The central part of the kiln is used for burning the saggars in their clay state, and they are piled up from the floor to the roof of the kilns.

The ware, as it comes from the first fire, is sufficiently burned to be entirely safe in handling, but can be easily broken between the thumb and finger. It is glazed in the ordinary way by dipping it in tubs of thin liquid glaze. The ware dries rapidly and is ready for the second fire after the bottoms and edges of the cups have been cleaned of glaze to prevent sticking.

The French methods of placing the ware are used. The plates, dishes, and flatware are placed in separate setters. All cups and bowls are put on rings, which are placed on the bottom of the saggar, and are not boxed as is customary in France. The plate setters are so evenly made that it is not necessary to fill in the edges with clay when fired. The fire of the glost kiln attains a heat equivalent to a No. 17 cone. These cones are made and supplied to the manufacturers by the Tokyo Kogyo Shikhenjo (Tokyo Industrial Laboratory). The drawing of the ware from the kiln is done with great care and rapidity, the unusual rapidity being induced by the fact that the man in charge is given a bonus for every hour saved.

The warehouse work in connection with the plant under consideration differs in many respects from the work of a similar kind in other parts of the world. Every piece of ware is carefully inspected and sorted and placed in four groups according to quality, namely, firsts, seconds, thirds, and job lots. About 10 to 15 per cent. are firsts, 25 per cent. seconds, and 35 to 40 per cent. thirds. Only firsts are exported. About fifty or sixty persons, mostly girls, are employed in the polishing-room. In addition to the perpendicular power-driven whirler for polishing the rims of such pieces as sugar bowls, teapots, etc., and lathes or horizontal wheels for buffing the edges of cups, small wheels mounted on flexible shafts, such as are used by dentists, are employed for the polishing of imperfections otherwise difficult to reach.

The decorating processes are similar to those in use in other countries, including decalcomania transfer work, printing and filling in, hand painting, ground laying, hairbrush tinting, gold-paste work, gilding, and etching. The dinner ware is decorated largely by mechanical processes, but very large quantities of decorative ornamental wares are hand painted.

After the ware has been sorted and examined it is taken to the packing establishment. It is first wrapped in paper, then taken to another room and packed with excelsior wrapping in cardboard boxes, each box being tied and labelled. It is then packed in large wooden cases and marked for shipment. These wooden packing cases, as well as the cardboard boxes, are made in the establishment.

One of the newer developments in the pottery industry is the manufacture of electrical accessories in connection with the rapidly expanding electrical industry in Japan. The large high-tension insulators demanded by hydro-electric development are made both in large factories, such as the great Morimura plant at Nagoya, and also by small individual workshops (on sub-contracts) in villages.

The large pole insulators are thrown on an ordinary wheel which usually is motor driven. When shaped they are passed to a second man who turns them to size with a tool. Finally they are carefully finished by hand before drying. They are glazed in the clay and fired once. One man carrying through all the processes will throw, turn, and finish four hundred insulators in a day, for which he gets about 1·70 yen (including a rice stipend).

Smaller white porcelain goods, insulators, cleats, rosettes, etc., are for the most part manufactured in Japan in the households alongside of dolls and teapots. They are moulded in plaster of Paris moulds, with a lavish expenditure of time and energy, from clay purchased ready for working, and are then fired in community kilns. With practically no overhead charges, such small manufacturers are able to compete successfully with modern factories. In fact, one large establishment which put in an insulator factory has been undercut in price by the small independent potters to such an extent that it has almost ceased to do business.

Dolls are made in nearly all the pottery centres of Japan along with other porcelain wares of every description. Few, if any, factories of any size devote themselves to the exclusive production of such goods. The world demand for toys during the war, due to the lack of German goods, has stimulated the production of Japanese toys. A large number of "Kewpie" dolls, in particular, are now made in Japan. One establishment in Seto devotes itself almost wholly to the manufacture of kewpies, with a production of one thousand a day. The factory cost of a 6-inch doll of this sort is approximately 5 sen (1¼*d.*) for the body and 5 sen for the decorating; total, 10 sen, or 2½*d.*

OIL-BEARING SEEDS AND NUTS IN GUATEMALA.

There is practically no vegetable-oil industry in Guatemala, excepting the production of a small

amount of castor and citronella oils. The oil-bearing seeds and nuts growing in that country, from which oil may be extracted, are the castor bean, citronella, cohune (corozo), coconut, sesame, and avocado.

Castor oil is produced in different sections of the country, principally in Antigua, Guatemala, and Escuintla. The output from the plant in Antigua has been estimated at about 3,000 gallons per year. The total exports from Guatemala in 1918 and 1919 were as follows:—1918, 23,378 lb., valued at 6,779 United States dollars; 1919, 27,400 lb., valued at 7,946 dollars.

The products of the royal palm tree are variously known as the corozo and cohune (coquito or coquillo). These nuts are all supposed to belong to the same general family, but have variations in size, shape, and oil-producing properties.

The corozo nut is found only in Guatemala and the southern part of Mexico. According to a report by the United States Vice-Consul at Guatemala City, it is estimated, after a recent survey made by Americans, that 100,000 tons of kernels may be produced annually. Twelve tons of nuts will furnish 1 ton of kernels, and these kernels yield about 52 per cent. of oil. The corozo nut grows only on the Pacific slope.

The cohune (coquito or coquillo) nut grows only on the Atlantic slope, and it is estimated that 60,000 tons of kernels may be collected annually. Ten tons of nuts will yield 1 ton of kernels, and the kernels will yield 67 per cent. of oil. An analysis of the oil produced from these nuts showed as follows: Water 3·28 per cent.; oil (as received), 67·20 per cent., equivalent to oil (moisture-free basis), 69·48 per cent. This is strictly a laboratory percentage of oil. Commercially, by the same process as copra oil is extracted, the corozo and cohune or coquito palm nut kernel yield 65 per cent. of oil, this oil containing a certain percentage of glycerine. Soap manufacturers claim that this particular vegetable oil produces a better lather soap than other oils.

What is called coquillo is exactly the same as the cohune, only the outside shell is thorny and pear-shaped. The royal palm nut tree grows wild and bears after 20 years, and up to 75 years. It bears nuts the whole year, with the principal maturing season from November to May. Eight months are required for the nut to mature.

There are several difficulties to be encountered in collecting these nuts in Guatemala. They are widely scattered, and it is difficult to transport them to the machinery for cracking and extracting the oil. They must be transported through swampy ground and almost impenetrable jungles on mule back or on the backs of mozos (porters). No satisfactory machine has, as yet, been designed to crack the nuts, and get out the kernel commercially.

The avocado grows in great profusion in Guatemala, and it is at present a subject of study by Mr. Wilson Popenoe, agricultural explorer for the United States Department of Agriculture. His bulletin entitled "The Avocado in Guatemala," published by the United States Department of Agriculture (Bulletin No. 743), gives a complete description of this fruit. It has been stated that the avocado oil is suitable not only for soap making and similar uses, but also makes a delicious salad oil. There should be a field in Guatemala for the extraction of this oil commercially.

OBITUARY.

ALFRED SIMSON.—Mr. Alfred Simson, a well-known East India merchant, died suddenly at Folkestone on September 6th in his seventy-third year. Senior partner of Messrs. Kilburn, Brown & Co., of London, and of Messrs. Kilburn & Co., of Calcutta, he was also Chairman of the Indian General Navigation and Railway Company, Chairman of the Caamaño Tenguel Estate, Limited, a director of the National Bank of India and of the Colonial and Foreign Banks Guarantee Corporation, and formerly Consul-General for Denmark in Calcutta. While a resident in Calcutta he rendered valuable services to the Indian Museum, and for some time was honorary secretary of the Zoological Gardens in that city. A great collector of rock crystals and chalices, some of his Indian specimens were lent to the Victoria and Albert Museum. A number of exquisite examples of artistic work in quartz from his collection were also exhibited at the Royal Society of Arts nine years ago to illustrate the course of Cantor Lectures on "Rock Crystal: its Structure and Uses," delivered by Dr. Alfred E. H. Tutton, F.R.S. Mr. Simson joined the Society in 18[illegible], and was always much interested in the work of the Indian Section, particularly in all endeavours to accelerate and extend industrial development in our Eastern Empire. He paid special attention to the improvement of the inland waterways of Bengal and Assam, and took part in the discussion which followed the reading of an important paper on the subject by Mr. R. B. Buckley, C.S.I., in 1906.

NOTES ON BOOKS.

NOTES ON CARPET-KNOTTING AND WEAVING. London: H.M. Stationery Office. 9*d.* net.

This small pamphlet, issued under the direction of the Department of Textiles at the Victoria and Albert Museum, may be taken as a supplement to a larger and more important "Guide to the collection of Carpets" published by the same Department in 1915. It deals with the technique of hand knotted and hand woven carpets of the kind so largely made during many centuries in Persia, Turkey, and other countries in the East. The main purpose of the author, Mr. C. E. C. Tattersall, of the Victoria and Albert Museum, it would appear, is to give information to those who may be led to attempt carpet making for themselves. For this purpose the booklet contains a number of plates illustrating in diagrammatic form the various knots in use in the Orient. In principle they are

chiefly two, the one known as the "Ghiordes" or "Turkish" knot, the other the "Sehna" or "Persian" knot. Mr. Tattersall furthermore deals with the Oriental tapestry weave, and more particularly illustrates the one which is used in the manufacture of the "Soumak" (Caucasian) carpet. The illustrations on "Selvedges," always so important in the life of a carpet, give very useful information how selvedges should be worked and finished, whilst the information contained in the illustrations of fringes on the ends of carpets and rugs form an instructive lesson on the finished article.

The authorities at South Kensington are doing a good service in their effort to encourage the manufacture of rugs and carpets. We cannot, however, imagine they advocate a revival of hand-knotted carpets and rugs as an industry. Such a proposition in our opinion is doomed to failure; the cost of labour would alone make it impossible of success in this country. If, on the other hand, it is their idea that gentlefolk should take up the work as a pastime or recreation, thus enabling them to make rugs as part of their dowry, just as in the East every girl is a knotter and weaver of rugs; or if, to develop the idea a step further, the learning of such an industry may, in their judgment, be the means of producing very fine grades of rugs of very special designs, which might command a market amongst the more wealthy in our land—then the idea is a good one, and with the co-operation of wool spinners who may see their way to stock suitable yarns, the scheme has some possibilities of success.

Coming from the Museum, the booklet makes no pretence to instruct one on all that has to be learnt about rug-making, a task which belongs more to the Schools of Art.

The introduction of a "William Morris" carpet loom, which figures at the end of the booklet, will help the reader to judge how simple and inexpensive is the machinery needed to outfit the would-be rug-maker.

On the whole, the pamphlet should form an adjunct to text-books on the craft industries, applicable alike to the technical side of Schools of Art and to the workshops of the machine-made carpets.

As Mr. Tattersall has made almost microscopical examinations on knots in use in Turkey and Persia, we commend for his further investigation an interesting problem, viz., to trace the influence or the migration of the "Turkey" knot in Eastern Persia, Central Asia, Afghanistan and India, and to try to explain how the "Turkey" knot came to be used in countries where one would expect the "Persian" knot to have been paramount.

GENERAL NOTES.

Victoria and Albert Museum. — By the generosity of a body of subscribers, substantially aided by the National Art-Collections Fund, the Victoria and Albert Museum has acquired a specimen of one of the rarest and most keenly sought of early Chinese porcelains—the celebrated Chün ware of the Sung dynasty. Hitherto, though more than one American museum can show examples of this beautiful ware, in England it could be studied only in private collections. This new addition to the treasures of the nation is a shallow bowl for growing bulbs in of the finest quality. It is of the usual form with three small feet and, round the side, a row of studs in relief. The glaze on the outside belongs to the class of "transmutation" glazes, with variegated colouring produced solely by skilful management of the firing, imitated in the well-known *rouges flambés* of the eighteenth century; its colour is predominantly crimson, with curd-like flecks of bluish-white and passages of fiery rose. The inside is covered with a cloudy greyish-lavender glaze showing where contraction has occurred in the firing the so-called "earthworm" markings characteristic of early wares of this type. The under side has a brown glaze with olive-green markings, and bears the numeral *t'ai* (7), indicating the size of the vessel, cut through the glaze before firing; it also displays another feature of the true Chün porcelain, a ring of scars left by the breaking away of the "stilts" or "cockspurs" used for support in the kiln.

Production of Raggee Flour in Malaya.—Owing to the shortage of rice, the Government of the Federated Malay States obtained legislative powers for the compulsory growing of foodstuffs for the labourers. The foodstuffs cultivated included raggee, hill paddy, and sweet potatoes. In the case of raggee, reports the United States Consul-General at Singapore, a recent demonstration made on the Golconda rubber estate, Kapar, showed that by the use of machinery raggee flour could be satisfactorily produced, and that it would pay planters to grow enough for their own requirements, or to buy locally grown raggee as a substitute for part of the rice they purchase at present. It has been suggested, as a result of the success of the Golconda demonstration, that planters in a district should combine and have one central place for the preparing of their raggee. Malaya, as a whole, has relied almost entirely on outside sources for its supplies of food, and the rice shortage has come as a blessing in disguise, by turning the attention of both the Government and the people to making that country more or less self-contained as far as food supplies are concerned.

THE LIBRARY.

The following books have been presented to the Library since the last announcement. Except where otherwise stated they have been presented by the publishers:—

Andrews, S. T. G., B.Sc., and S. F. Benson, B.Sc.—The Theory and Practice of Aeroplane Design. London: Chapman & Hall, Ltd., 1920.

Baker, Richard T.—The Hardwoods of Australia and their Economics. Sydney: W. A. Gullick, 1919.

Beaumont, Roberts, M.Sc., Union Textile Fabrication. London: Sir Isaac Pitman & Sons, Ltd., 1920.

Bolton, Arthur T., F.S.A.—Description of Sir John Soane's Museum. Tenth Edition, 1920.

Burrow, Edward J.—The Ancient Entrenchments and Camps of Gloucestershire. Cheltenham: Edward J. Burrow & Co., Ltd., 1919.

Cahen, Edward, A.R.C.S., F.I.C., and William Ord Wootton, A.R.C.S., B.Sc.—The Mineralogy of the Rarer Metals. Second Edition. London: Charles Griffin & Co., Ltd., 1920.

Calcutta, Imperial Library—First Supplement to Author-Catalogue of European Books. Two Vols. Calcutta, 1917 and 1918.

Campbell, William.—Modern Business and its Methods. London: Sir Isaac Pitman & Sons, Ltd., 1919.

Clark, Alice.—Working Life of Women in the 17th Century. London: George Routledge & Sons, Ltd., 1919.

Currencies after the War. Compiled by the International Secretariat of the League of Nations. Harrison & Sons, 1920.

Darling, Charles R.—Pyrometry. London: E. & F. N. Spon, Ltd., 1920.

Daw, Albert W., and Zacharias W. Daw.—Compressed Air Power. London: Sir Isaac Pitman & Sons, Ltd., 1920.

De Forcrand, Professeur R.—Cours de Chimie. Deuxième Édition. Deux Volumes. Paris: Gauthier-Villars et Cie., 1918 and 1919.

Filow, Dr. Bogdan D.—Early Bulgarian Art. Berne: Paul Haupt, 1919.

Fisk, Harvey E.—English Public Finance. New York: Bankers Trust Co., 1920.

Groves, E. J. A.—A Junior French Course. London: Blackie & Son, Ltd., 1919.

Hall, H. R. Wilton.—Social Life in England. Blackie & Son, Ltd., 1920.

Hardie, Martin, A.R.E.—Catalogue of Modern Wood-Engravings in the Victoria and Albert Museum, 1919.

Harvey, Arthur.—Practical Leather Chemistry. London: Crosby Lockwood & Son, 1920.

Hayward, F. H., D.Lit., M.A., B.Sc.—A Second Book of School Celebrations. London: P. S. King & Son, Ltd., 1920.

Henry, Augustine, M.A., F.L.S.—Forests, Woods and Trees in Relation to Hygiene. London: Constable & Co., Ltd., 1919.

Howard, Alexander L.—A Manual of the Timbers of the World. London: Macmillan & Co., Ltd., 1920.

Johnson, V. E., M.A.—Model Aeroplaning. London: E. & F. N. Spon, Ltd., 1920.

Lawson, F. M.—Industrial Control. London: Sir Isaac Pitman & Sons, Ltd., 1920.

Lempfert, R. G. K., M.A., C.B.E.—Meteorology. London: Methuen & Co., Ltd., 1920.

Makower, W., D.Sc., et H. Geiger, Ph.D.—Mesures Pratiques en Radioactivité. Traduit de l'Anglais par E. Philippi. Paris: Gautier-Villars et Cie, 1919.

Malatesta, Dr. G., Coal-Tars and their Derivatives. London: E. & F. N. Spon, Ltd., 1920.

Martin, Edward A., F.G.S.—Life in a Sussex Windmill. London: Allen & Donaldson, Ltd., 1920.

Moureu, Charles, Professeur au Collège de France. —Notions Fondamentales de Chimie Organique. Sixième Édition. Paris: Gauthier-Villars et Cie, 1919.

Müller-Lyer, Dr. F.—The History of Social Development. Translated by Elizabeth C. Lake and H. A. Lake, B.Sc. London: George Allen & Unwin, Ltd., 1920.

Napier, Robert W.—John Thomson of Duddingston. Landscape Painter. Edinburgh: Oliver & Boyd, 1919. Presented by the Author.

Penger, N. M., B.A.—Cotton in British West Africa. London: Federation of British Industries, 1920.

Pool, Rev. John J., Ph.D., B.Sc.—Colour and Health. London: Cope & Fenwick, 1919.

Price, J. B., M.A.—A Spanish Reader, 1919.

Rawlley, Ratan C., M.A., M.Sc.—Economics of the Silk Industry. London: P. S. King & Son, Ltd., 1919.

Roget, F. F.—Altitude and Health. London: Constable & Co., Ltd., 1919.

Rose, W. N.—Mathematics for Engineers. London: Chapman & Hall, Ltd., 1920.

Routley, John.—Business Book-keeping. London: Sir Isaac Pitman & Sons, Ltd., 1919.

Russell, Thomas.—Commercial Advertising. London: G. P. Putnam's Sons, Ltd., 1919.

FRIDAY, OCTOBER 8, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

INDIAN SECTION.

SPECIAL MEETING.

On FRIDAY, OCTOBER 15th, MR. THOMAS M. AINSCOUGH, O.B.E., His Majesty's Senior Trade Commissioner in India and Ceylon, will read a paper on "British Trade with India."

The chair will be taken at 4.30 p.m. by SIR CHARLES C. MCLEOD.

EXAMINATIONS, 1920.

Perhaps the most remarkable feature of the academic year 1919-20, was the enormously increased demand for educational facilities of every description. Universities, technical colleges, day schools and evening schools were suddenly called upon to provide accommodation for far larger numbers of students than they had ever housed before. The principal causes were twofold, one temporary, the other permanent. In the first place, a great many students were anxious to complete their courses of study which had been interrupted by the war; and in the second place, owing to the Fisher Act, and a more general recognition of the necessity for education, a greater proportion of the rising generation are aiming at a higher standard of education than that which contented their fathers.

One of the effects of these causes is shown in a remarkable way in the statistics of the Society's Examinations. It will be seen from the diagram on page 740 that the total number of papers worked rose from 31,132 in 1919 to 49,390 in 1920—an increase of about 60 per cent. These increases occurred in almost every subject of examination, but the most noticeable were in Book-keeping, where the number of papers rose from 9,151 in 1919 to 15,241 in 1920, and in Shorthand, where the number of papers rose from 8,202 to 12,411.

The usual examinations were held at two periods, March and May, as has been the case since 1915. In March, the number of entries was 17,684, and in May, 36,357. The papers worked were divided between the two examinations as follows:—

	March.	May.	Total.
Advanced Stage .	1,642	5,421	7,063
Intermediate Stage	5,102	13,514	18,616
Elementary Stage	9,497	14,132	23,629

In addition to the 49,390 papers worked in the written examinations, 431 candidates presented themselves for the *viva voce* examinations in modern languages, making a total of 49,821.

The principal changes in the examinations programme for 1920 were the discontinuance (for reasons given in the last Report *) of English for Foreigners, Rudiments of Music, and Harmony. There will, however, be some important changes in the Programme for 1921, to which attention is drawn on page 738. The subjects of examination this year were:—Arithmetic, English, Book-keeping, Shorthand, Précis-writing, Typewriting, Economic Geography, Economic History, Economic Theory, Commercial Law, Company Law, Accounting, Banking, Theory and Practice of Commerce, Commercial Correspondence and Business Knowledge, French, German, Italian, Spanish, Russian, Dutch, Danish and Norwegian, Portuguese, and Swedish.

In Arithmetic the total number of papers worked was 3,988, as compared with 2,814 last year. 130 candidates entered in Stage III., of whom 18 obtained first-class certificates, 44 obtained second-class certificates, and 68 failed. The Examiner reports that while some excellent papers were worked in this Stage, the results on the whole were poor. About half the

* See *Journal* of November 7th, 1919, page 780.

candidates were not nearly up to the standard, many of them being unable to answer a simple question in logarithms. Unfortunately, his report on the work in Stage II. is still more unfavourable. Of 1,022 candidates 59 obtained first-class certificates, 383 obtained second-class certificates, and 580 failed. Style and accuracy were worse than in the Stage I. papers, and the great majority of the candidates were quite unprepared in the subject-matter of the syllabus. In Stage I., of 2,836 candidates, 1,819 passed and 1,017 failed, and the examiner was on the whole satisfied with the work of these students.

It is gratifying to note that the number of candidates in English rose from 1,169 in 1919 to 3,351 this year. Part of the increase is no doubt attributable to the fact that English was one of the subjects of competition for the *Daily Sketch* prizes.* In Stage III. there were 88 candidates of whom 10 obtained first-class certificates, 43 obtained second-class certificates, and 35 failed. In Stage II., of 1,237 candidates, 185 obtained first-class certificates, 711 obtained second-class certificates, and 341 failed. In Stage I., of 2,026 candidates, 1,367 passed and 659 failed. The Examiner reports a slight general improvement in the work in Stages I. and II. He criticises the work submitted in considerable detail, and his remarks should be studied with great care, both by students and teachers.

Reference has already been made to the very large increase in the number of candidates in Book-keeping—15,241, as compared with 9,151 last year. In Stage III., of 2,772 candidates, 351 obtained first-class certificates, 1,287 obtained second-class certificates, and 1,134 failed. In Stage II., of 5,648 candidates, 768 obtained first-class certificates, 3,608 obtained second-class certificates, and 1,272 failed. In Stage I., of 6,821 candidates, 4,161 passed, and 2,660 failed. The Examiner points out that in Stages I. and II., even when the exercises are well worked, the answers to the questions are often exceedingly poor, and some of the specimens which he quotes are simply nonsensical.

Shorthand, as usual, comes next to Book-keeping in popularity. The entries totalled 12,411, as compared with 8,202 in 1919. 990 candidates entered for Stage III., of whom 57 obtained first-class certificates, 386 obtained second-class certificates, and 547 failed. 6,152 entered for Stage II.; of these 917 obtained first-class certificates, 2,344 obtained second-class certificates, and 2,891 failed. 5,269 entered in Stage I., and of these 3,913 passed, while 1,356 failed.

In Typewriting, the entries rose from 3,011 in 1919 to 4,634 this year. Of these 428 entered for Stage III.: 137 secured first-class certificates, 154 secured second-class certificates, and 137 failed. In Stage II. there were 1,639 candidates, of whom 508 obtained first-class certificates, 698 obtained second-class certificates, and 433 failed. In Stage I. 2,567 entered, of whom 1,799 passed and 768 failed. The work, on the whole, appears to have been quite satisfactory, although in commenting on the work in Stage I., the Examiner mentions that many centres are turning out operators "regardless of everything but the ability to operate a typewriter with more or less skill." It is obviously useless to train as typists boys and girls who "cannot spell the most elementary words correctly, and are ignorant of the elements of English composition."

The number of entries in Précis-writing is still small. There were only 122 candidates in all, as compared with 100 last year. 34 entered in Stage III., and of these 5 obtained first-class certificates, 19 obtained second-class certificates, and 10 failed; while in Stage II. of the 88 candidates 10 obtained first-class certificates, 49 obtained second-class certificates, and 29 failed. Considerable changes have been made in the Syllabus for 1921, and it is hoped that these may render the examination more popular and more practically useful.

The entries in Accounting made a remarkable increase to 582, as compared with 179 last year. 74 obtained first-class, 335 obtained second-class certificates, and 173 failed. The Examiner reports that the general average of the work showed an improvement on that of 1919, although the percentage of first-class certificates was a little lower. In Banking there were 75 entries, as compared with 26 last year: 8 obtained first-class and 34 obtained second-class certificates. Several excellent papers were sent in, evidently by candidates with sound practical knowledge.

In Economic Geography the total number of entries rose from 202 last year to 275: 31 entered in Stage III., 76 in Stage II., and 168 in Stage III. It is satisfactory to learn that the Examiner reports considerable improvement in the work in all three stages. Similarly, in Economic History the entries rose from 47 in 1919 to 92—23 in Stage III. and 69 in Stage II. According to the Examiner, the work

* See page 738, below.

submitted in Stage III. was very markedly better than that in Stage II., which was generally of a poor character, only 3 candidates out of 69 securing first-class certificates.

183 candidates entered in Economic Theory, as against 82 last year. 79 sat for Stage III., and 104 for Stage II. The Examiner's report shows that the work, on the whole, was quite satisfactory, although in Stage III. out of the 79 candidates only 4 obtained first-class certificates.

The entries in Commercial Law rose from 95 in 1919 to 429 this year. The papers reached an unusual standard of excellence, no fewer than 131 candidates obtaining first-class certificates, while 230 obtained second-class certificates, and only 68 failed. There was a similar increase in Company Law, where the entries rose from 85 to 278; and here, too, the Examiner reports very favourably on the general standard of the work submitted.

In Theory and Practice of Commerce the numbers have also risen satisfactorily from 215 last year to 566, of whom 142 entered in Stage III., and 424 in Stage II. In both examinations there appears to have been a very decided improvement in the quality of the papers.

The entries in Commercial Correspondence and Business Knowledge rose from 2,402 in 1919 to 3,147. In Stage III. there were 58 candidates, of whom 5 obtained first-class certificates, 21 obtained second-class certificates, and 32 failed. In Stage II. of 710 candidates 33 obtained first-class certificates, 449 obtained second-class certificates, and 228 failed. The Examiner comments on the large proportion of successful candidates in this stage, but regrets the absence of papers of real distinction. In Stage I. there were 2,379 candidates, of whom 1,577 passed and 802 failed.

In French there was a satisfactory advance in the numbers from 2,427 in 1919 to 3,058. Of these 740 entered for Stage III.; 1,168 for Stage II.; and 1,150 for Stage I. The Examiner reports very favourably on the work in each Stage, and comments on the small proportion of failures—157 in Stage III., 171 in Stage II., and 258 in Stage I.

The entries in German (252) show a slight increase on those of last year (202), but this subject has by no means recovered the popularity which it lost on the outbreak of the war. In 1914 the total number of entries was 826, and this fell to 181 in 1918. The standard of work in Stage III. was exceptionally high: out of 62 candidates 25 obtained first-class certificates, and only 5 failed.

There were 77 entries in all stages of Italian, as compared with 47 last year.

The popularity of Spanish continues to grow, the entries being 551 as compared with 386 last year, which was the previous highest figure. Unfortunately, the quality of the work submitted leaves a good deal to be desired. Out of 83 candidates in Stage III. only 4 obtained first-class certificates, while in Stage II. out of 210 candidates only 26 obtained first-class certificates.

It is curious to observe how the number of entries in Russian has varied with the fortunes of that unhappy country. In 1917 there were 266 candidates; in 1918 the number fell to 157; in 1919 there were 79, and this year only 56. The Examiner reports that the work in Stage I. is distinctly better than last year.

In Danish and Norwegian there were only 3 candidates, as against 14 last year; in Dutch 7 as against 4; in Portuguese 7, and in Swedish 5. In the last two subjects no examinations had been held for some years.

Oral examinations were held in French, German, Italian, Spanish and Russian. The total number of candidates was 431 (as compared with 351 last year), and examinations were held at Coventry, Liverpool, Manchester and York, as well as at the usual London centres. The numbers in the different languages were: French 351, German 36, Italian 5, Spanish 37, Russian 2. The details of the results of the oral examinations are given in Table B (page 741).

The Court of the Clothworkers' Company have again renewed their grant of £40, to be expended in providing medals in all the subjects of examination where the work of candidates attains a sufficiently high standard. There is no doubt that these medals are highly valued by those who win them, and they have done much to maintain or raise the level of excellence in the papers worked.

The Examination Syllabus for 1921* has been issued. In it will be found the fullest possible information about the examinations, a syllabus of each stage of each subject, and a list of centres. The papers set in March and May, 1920, have been reprinted in six pamphlets.

* The price of the Syllabus for 1921 is 4*d*., post free. Copies can be obtained on application to the Examination Officer, Royal Society of Arts, Adelphi, London, W.C. (2). The price of the pamphlets containing the 1920 papers is 4*d*. each, post free. Particulars of these may be obtained as above.

Each pamphlet contains, in addition to the papers of each stage, the syllabuses of the subjects in the pamphlet and the Examiners' reports on the papers worked in 1920. The attention of both teachers and students may be drawn once more not only to the syllabuses but also to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially are earnestly recommended to study these reports, as they ought to be guided by them in the instruction they give to their pupils.

The regulations for the Oral Examinations in Modern Languages are also given at full length in the syllabus.

Alterations in the Syllabuses.

The Council have given careful attention to the syllabuses in the various subjects of examination. These have been revised by small curriculum committees, on which every effort has been made to secure the representation of teachers. A considerable number of alterations have been made, which it is hoped will keep the syllabuses in line with the most modern educational requirements. It is impossible in this report to mention all the changes in the syllabuses, of which students and teachers are recommended to make a careful study; but attention may be called to the more important alterations.

Oral Examinations in Foreign Languages.—As stated in the Syllabus for 1920, Vivâ Voce Examinations will be compulsory in 1921 and thereafter for all candidates entering for French, German, Spanish and Italian in Stage III. (Advanced). The Oral Examinations will include Conversation, Reading, and Dictation, and will be held on dates subsequent to the written Examinations. No candidate will be awarded a certificate who does not pass in this part of the test. Candidates will be grouped together for the Oral Test at various centres, and those residing at outlying districts must be prepared to travel some distance.

English (*Stage II.*).—In future candidates will be required to have some knowledge of two prescribed books. For 1921 these will be Shakespeare's "The Tempest," and Scott's "Quentin Durward."

Shorthand (*Stage I.*).—The speed in this stage will be 60 words per minute, instead of 50 words per minute as heretofore.

Arithmetic (*Stage I.*).—Two papers will be set in this Stage, the first being designed as a test of "Mental Arithmetic," while the second will be of the same type as those set in recent years.

Précis-writing.—In future there will be a much greater variety in the materials set than in former years, and candidates will no longer be required to draw up schedules of correspondence.

Railway Law and Practice and *Shipping Law and Practice* have been added to the subjects of examination in Stage III.

Increase of Fees.

In order to raise the fees paid to the Examiners which still remain on their pre-war basis, and to meet the greatly increased cost of printing and paper, it has been found necessary slightly to raise the fees paid by candidates. In future these will be as follows:—

Stage III. (Advanced): 4*s.* per subject, except for French, German, Spanish and Italian for which the fee will be 7*s.* per subject.

Stage II. (Intermediate): 3*s.* 6*d.* per subject.

Stage I. (Elementary): 2*s.* 6*d.* for the first subject, and 2*s.* for each additional subject taken by the same candidate.

"Daily Sketch" Prizes.

It was announced in last year's Report that in order to encourage the study of Typewriting and Shorthand, and to assist in ensuring the supply of efficient and educated shorthand typists, the Proprietors of the *Daily Sketch* had offered a sum of £1,000 in prizes in connection with the Society's Examinations in 1920. In the Advanced Stage the prizes amounted to £675, the first prize being £250; in the Intermediate Stage the prizes amounted to £250, the first prize being £60; and in the Elementary Stage the prizes amounted to £75, the first being £10. The subjects of examination in each stage were Typewriting, Shorthand, and English. These were taken at the Society's ordinary examinations in March and May. In the Elementary Stage the prizes were awarded on the result of these examinations without any further test. In the Advanced and Intermediate examinations a number of candidates were selected to compete for the prizes. The final test was held, by kind permission of the Director of Education, at the Polytechnic, Regent Street, on September 25th, when 25 selected candidates presented themselves, 12 in Stage III., and 13 in Stage II. The results have now been communicated to the proprietors of the *Daily Sketch*, and the list of prize-winners will be published in the *Journal* shortly.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

RECENT RESEARCH IN CELLULOSE INDUSTRY.

By CHARLES FREDERICK CROSS, B.Sc., F.R.S.

Lecture III.—Delivered March 1st, 1920.

PROBLEMS OF CONSTITUTION.

Students of "organic" chemistry are warned, generally in the opening chapter of the systematic text-books, of the errors of our forefathers in treating "organic compounds" as an inaccessible group of bodies, formed and supplied exclusively as products of life, *i.e.*, of the plant or animal cell. It appears necessary, as a retrospect, to eliminate from the natural philosophy of the subject, an error or superstition of the "old school"; as a matter of history the modern science has developed largely by way of synthesis of "organic" chemical individuals incidentally detached from theories of life, and animated by an objective spirit of research. The results appear to justify the philosophy. It is, however, a feature of science progress that the errors of a school or generation in regard to phenomena, are recognised at a later period as an adumbration of an essential aspect of generalised causes. Thus, "phlogiston" suggests the energy factor of reaction, and Newton's treatment of Light has some suggestions of modern discoveries which go behind the

theories of Young and their physical consequences.

The subject matter of these lectures is impressive of a definite return to the perspective of Natural History, in the treatment of organic compounds: their fundamental chemistry may be so linked with the biology of the genesis of strictly "organic" compounds—those carbon compounds which are formed as structurally organised bodies—that the progressive investigation of the ultimate structure of these natural products may contribute generalisations affecting the science as a whole.

This is not generally admitted as a probability, though it would be accepted as a possibility, but so remote as to be without influence on the method or scope of investigations, or on the interpretation of their results.

On the concrete problem of the constitution of cellulose, there has grown already an extensive literature. "Cellulose" reacts to form synthetic derivatives: (*a*) nitrates, acetates, benzoates, mixed esters, and hydrate-esters, with quantitative relations such as exactly to measure the reacting groups; (*b*) ether products, of which the methyl and ethyl derivatives have been more closely studied: it is resolved into well-defined proximate products; (*c*) by anhydrous reactions, *e.g.*, bromo-methyl furfural (Fenton), laevoglucosan (A. Pictet); (*d*) an indefinitely varied series of decomposition products, more nearly related to the original cellulose, the oxycelluloses, hydrocelluloses, hydrate-celluloses, resulting from the action of oxidants, hydrolysers, acid and alkaline, and reducing agents, in water as reaction medium, and complicated by hydrations and dehydrations. Lastly, "cellulose" is resolved by bacteria to ultimate products: liquid (alcohols and fatty acids), and gaseous, (CO_2 and CH_4).

All these reactions have been impressed into the service of the investigator of the constitutional problem or problems.

It would be outside our present purpose to attempt a review of the literature of the subject; but we may refer to a recent record of investigations in the best traditions of what we may call the *haute école*, a paper by K. Hess and W. Wittelsbach, with the sub-title "Acetolyse der Ethyl-Cellulose" [Ztschr. Electrochem, 26 (1920) 232-251] abstr. J. Chem. Soc., 1920, i. 532.

This is a close study based on the controlled dissection of the acetylated derivatives (Ost); and in the discussion of results the authors infer that the solvent actions of saline solutions (*e.g.*, $Zn.Cl_2$—M'.CNS) are the result of interaction with the residual valencies which cause the complexity of the "cellulose molecule." It is also noteworthy that the discussion touches the question of the relation of visible structure, *i.e.*, organic form, to constitution, which is provisionally formulated in terms of a monose (dextrose) and a biose (cellobiose).

This is a valuable contribution to the subject, and is representative of a series of investigations which proceed on the accepted "grammatical" methods, which certainly presume their adequacy to solve the major problem.

This mode of attack, however, rules out of consideration a large number of problems which arise in the cellulose industries, whether considered as merely utilising natural raw material, or developing what we may call the "cellulose scheme" or plan of the organic world. This brings us back to the alternative perspective of the subject, that of its natural history, and to the question of the development of industry by the application of "science" in the modern sense.

Robert Boyle (ed. 1725, P. Shaw), has something to say on this general theme. "It may be expected," he writes, "that I should treat particularly of the principal means whereby a *naturalist* might advance *trades* and assist mankind to recover *part* of his lost empire over the works of Nature."

This is a pregnant forecast; and in regard to the present and future development of our subject, it is a fair inference from past progress that the main line of evolution follows "industry"; and reciprocally "industry" will follow science, provided the subject matter is not arbitrarily detached from its natural setting.

The developments in "artificial silk," *et similia* is a case in point, the bearings of which are evident without discussion.

The "viscose reaction" upon which these largely depend is an illustration of the difficulty of the scientific problem. There are two more recent contributions to the development of this section which must be noted.

In "Zellstoffviscose und Starkeviscose" [Annalen, 1911, 382-340-360] Ost (Westhoff and Gessner) investigates the viscose cycle, formation of the xanthogenate and spontaneous reversion in solution, and confirms, on a more extended basis of quantitative results, the first formation of $[C_6H_nO_3(ONa),OCS_2Na]_m$ and reversion through stages of C_{12} and C_{24}, dimensions of analogous products also characterised by an

(ONa) residue in the cellulose. The starch reaction is closely analogous; the xanthogenates are more stable; also the starch complex though apparently progressively hydrolysed, is not resolved to dextrins, but retains the essential properties and characteristics of the original starch. This investigation is based on methods which do not correspond with the factors of instability of the products, and only permit the identification of well-marked phases. It is obviously important to determine whether the reversion is actually "continuous" as it appears to be; and for this a quite special manipulation and detailed technique is required, as well as a full preliminary experience of the various types of cellulose, as such, and of their characteristic behaviour in the "xanthic" reaction cycle.

The "limited viscose reaction" previously mentioned (Lecture II.) has a bearing on the mechanism of the full reaction, giving a basis of independent observation of its hydration factors.

It is well known that the interaction of sodium hydrate (NaOH solutions) and fibrous cellulose is marked by variable "mercerising" effects, the effects of hydration and structural modification. Below 12 per cent. NaOH, at ordinary temperatures, the visible effects are small, and at 9–10 per cent. NaOH the change of dimensions is negligible. But in contact with the reagent, *and* exposed to the bisulphide, there is reaction with production of a fractional proportion of xanthogenate, and some change of dimensions.

Thus a square of bleached cotton cloth was reduced by 33 per cent. in square dimensions, under the reaction in question; in contact with 7 per cent. NaOH, and afterwards under reaction with CS_2, the loss was 7 per cent.

Of the chemical effects, the following data are typical:—

(1) *G. C. Cellulose, Normal Standard.*

In 10 gm. portions (9·3 grms. dry) treated 9 per cent. NaOH, in proportions (*a*) 1·0, (*b*) 1·5, (*c*) 2·0 times its weight, afterwards exposed to CS_2, and the reaction product diffused in water. The following were determined:—

	a	*b*	*c*
Total cellulose in solution,	0·213	0·308	0·224
of which as xanthogenate	0·160	0·255	0·171
Total combined sulphur (xanthogenic ester and by-products) . . .	0·342	0·399	0·366

(2) *G. C. Cellulose.*

Extreme reaction with three times weight, 9 per cent. NaOH. Total cellulose dissolved, 0·614 from 9·3 grms. dry. The fully washed fibrous hydrated mass was treated with an equal weight of mercerising soda (17·5 per cent. NaOH). After diluting and filtering the solution was acidified, and the cellulose precipitate collected and weighed = 4·530 grms.

(3) *Raw Cotton* was profoundly attacked under treatment as follows:—10·0 grms. (a.d.) in the form of sliver, immersed in 9 per cent. NaOH at 100°, immediately removed and squeezed to 30·0 grms. total weight. After reaction with CS_2, washed on vacuum filter. The hydrated mass weighed 170 grms., and correlative with this extreme hydration, the cellulose showed an increased solubility in soda, a 9 per cent. solution dissolved 50 per cent.

Attention has been called to the effects of the hydration in enormously exaggerating the dimensions of the fibre, while conserving its structural details. From the point of view of the chemical effect, it is another example or proof of "continuous reactivity" in or of the cellulose system. This is a statement or conclusion obviously open to discussion. It involves the open question of the reacting unit or "the molecule" as usually defined, and this will be referred to subsequently.

In continuation of the present theme, there are other problems arising out of the industrial application of cellulose, which have a bearing on the deeper problems of constitution; they are only mentioned here, with the reference to the original papers wherein they are recorded and discussed (J. Soc. Dyers and Col. 1918: 215, 247, and 1919, 271). One is the exceptional case of destruction of a normal cotton cloth under the operation of beetling, to a microscopic powder, of a fundamentally modified cellulose. Another is the transformation of an original (untreated) cotton, the cotton yarn of a power-driving rope, to a structureless modification, taking the form of rounded hyaline masses. In either case there were no ascertainable causes of the fundamental changes of the cellulose substance, other than the mechanical-physical conditions of the respective operations. In this connection we refer to the brief description of Professor Robinson's investigation of the changes in lignocellulose structures under compression (R. S. Reports, Nov. 1919).

These are definite indications of fluidity, *i.e.*, a plastic variability of the fibre colloids, and it is in this order of suggestion that we have given attention to the volume-constants of

cellulose and derivatives. One aspect of these specific volumes is the subject of a paper published some years ago (Cross and Bevan, Berl. Ber. 42—1909—2198), and the matter is now under general and methodical investigation by Dr. S. Judd Lewis, as a section of the research scheme of Messrs. Courtaulds, Ltd. The experimental work involved presents exceptional difficulties, and the results require verification by repetition and carefully devised variations. Hence the delays in the publication of results of these extensive researches. They have been previously mentioned and discussed in outline, with the reservations in conformity with the recognised complications of the subject. The results continue to confirm the statements as to: (1) Large variations of apparent density of cellulose and derivatives, with variations of liquid medium, the displacement of which measures the volume; (2) large variations with changes of temperature; (3) general tendency to increase of (specific) volume, in the proximate products of modification, *e.g.*, hydrocelluloses, oxycelluloses, hydrate celluloses.

The principle which has dictated the undertaking of this research is fundamental; in complete ignorance of the ultimate forms of colloidal matter, the transition from parent substance to derivatives, under reaction, requires quantitative observation both of weight *and volume*, as a condition of inference from the derivative to the original substance or system. It is evident that we cannot define, in ultimate terms, what is expressed in specific volume; if we could, we could inferentially pass from starch to cellulose, or even from cellulose to gelatin in the interpretation of reaction changes. But with a given colloid, the volume *relations* of derivatives to original substance are certainly of fundamental import, and in the case of cellulose the neglect of this factor is an obvious weakening of the basis of conclusion as to the "constitution of cellulose," from investigations of derivative products.

This is by no means a criticism, in the sense of an under-estimate of the valuable contributions of experimental work of Ost, Willstätter, König and other representatives of "the School." It is rather limited to the underlying conception of "cellulose." The criticism may be extended to the too exclusive attention to cotton cellulose. Other well-established and differentiated types, more especially (pine) wood cellulose and esparto cellulose, should be studied by parallel investigations. As an illustration we refer to "Esparto Cellulose and the Problem of Constitution" (J. Chem. Soc. 113 (1918), 182). As a general suggestion, in regard to method, it would be important to extend the *scale* of such investigations involving the resolution to more or less ultimate products. Systematic quantitative records, based on the treatment of 1 to 10 kilos of original substance, would eliminate some of the uncertainties which attach to the ordinary laboratory scale of operation.

It is to be observed that systematic investigation of constitutional problems has abandoned the field of observation connoted by *Hydro-, oxy-, hydral-, and acid-cellulose.* These are proximate products of resolutions determined by reactions in presence of water: the products preserving obvious relationships, those of external resemblance, or those of physical characteristics as colloide, to the original cellulose. The complications presented by these series of derivatives are obvious and justify their being ruled out. It is hoped, however, that their inclusion in the scheme of determinations of specific volumes will lead to some general inferences of value, even on the problem of constitution. Attention may be called here to the work of Christian Bay (Dissertation Giessen, 1913) in association with Professor C. Schwalbe, and published under the above title. The investigation of well-defined types of these breakdown products establishes their common characteristics of the more general order, expressed in terms of the "Schwalbe constants." There is an inference to be drawn from this general resemblance of products of oxidation (MOCl and H_2O_2) and of hydrolytic actions of varying order (acid-alkaline) and intensity, viz., that the determining cause of change of the cellulose is rather intrinsic, than determined by the conditions of reaction. This has a bearing on the problem of constitution, but immediately has the value of a criticism of the specific value generally associated with the terms in question —notably "oxy-cellulose" and "hydro-cellulose."

In logical continuation of these destructive resolutions of cellulose, we again briefly mention the fermentations of cellulose, *i.e.*, the breakdown to ultimate products, liquid and gaseous. These are determined by various bacteria: and most effectively and rapidly by mixed organisms—symbiotic cultures. Observers appear to be agreed as to the general absence of intermediate products—products of "hydrolysis"—and that, from microscopic observation, the attack of the organisms is an attack *in situ*. This would accord with our observations of the

general characteristics of "cellulose" as those of a liquid system, and capable of "continuous" reactivity.

These processes are being brought so far under control that the periods required to break down an experimental mass of cellulose have been reduced from weeks (or even months) to days; and comparative observations with starch have demonstrated the equal and, under conditions, greater sensitiveness of the cellulose to the attack of the organisms. This is another of the many indications that the general reactivity of these natural colloids is an expression of positive characteristics rather than of inertness due to molecular complexity of the order of polymerisation.

It is not the purpose of this discussion to attempt any formal conclusions, and we may conclude this section by reminding students that it obviously involves the modern development of the subject of colloidal matter, for an account of which there are the "Reports on Colloidal Chemistry," i., 1917, ii., 1918, of the British Association Committee. And in this connection there may be mentioned the general trend of theory, to account for reaction and reactivity in terms of amphoteric dualism. A notable example of this is in a paper by R. Abegg, "Zur Theorie der Grignard'schen Reaktionen" (Berl. Ber., 1905, 4112), which may well be studied as a model. The applications to cellulose and starch reactions and reactivity are general and obvious. It must be an object of research to apply this method of critical interpretation more specifically. Thus, in Dr. Mary Cunningham's critical study of Willstätter's investigations of cellulose (J. Chem. Soc., 118, 1918, 180), there are incidental observations (1) of the formation of a hydrate-ester by treatment of cellulose with H_2SO_4 $2H_2O$; (2) of a pronounced acid function of constituent OH groups of the cellulose. These indicate a "basic-acid" polarity of cellulose definitely more pronounced than in the case of dextrose or the simple sugars, which are generally assumed, as anhydro-polymerides, to constitute the celluloses.

The problem of constitution is much widened and complicated when extended to the "compound celluloses," of which the prominent typical representatives are the ligno-celluloses and cuto-celluloses, connoting the physiological processes of wood formation, and the production of the external protective tissues of plant structures.

Of the former we have recently dealt in a paper "Lignone reactions and constitution" (J. Soc. Dyers and Col. 1916), and Lecture I. is intended as a definite forecast of progressive research on this subject.

In the cuto-celluloses we have also to refer to a recent publication of research work on a representative cuticularised tissue—the familiar raffia fibre (Cross and Bevan, *ibid.*, 35 (1919), 70). These researches are now extended to the esparto cuticle, which we have been able to separate in quantity, *i.e.*, as a mass of individualised cells, for investigation.

Reverting, in conclusion, to the more general aspect of these constitutional problems, they present themselves, on the one hand, as a section of the general theory of colloidal matter, and on the other as problems of organic growth.

As forms of matter the chemist treats them as such, and independently of origin or of the more general theories of matter. So far there is justification of this attitude; in reviewing the progress of science in this sphere we recognise a basis of empiricism: the test of results.

It is evident, however, that this basis is not permanently adequate, and that future progress must be more definitely assured by adopting the broader perspective of natural history.

INTENSIVE CULTIVATION DURING THE WAR.*

Although the work which intensive cultivators accomplished during the war is small in comparison with the great work performed by British agriculturists, yet nevertheless it is in itself by no means inconsiderable, and is, moreover, significant, and deserves a brief record. That work may have turned and probably did turn the scale between scarcity and sufficiency; for, as I am informed, a difference of 10 per cent. in food supplies is enough to convert plenty into dearth. Seen from this standpoint the war-work accomplished by the professional horticulturist—the nurseryman, the florist, the glass-house cultivator, the fruit-grower and market gardener, and by the professional and amateur gardener and allotment holder assumes a real importance, albeit that the sum total of the acres they cultivated is but a fraction of the land which agriculturists put under the plough.

As a set-off against the relative smallness of the acreage brought during the war under intensive cultivation for food purposes, it is to be remembered that the yields per acre obtained by intensive cultivators are remarkably high. For example, skilled onion-growers compute their average yield at something less than 5 tons to the acre. A chrysanthemum-grower who turned his resources from the production of those flowers to that of onions obtained over an area of several acres, a

* Extracted from the Presidential Address of Professor Frederick Keeble, C.B.E., Sc.D., F.R.S., to the Agricultural Section, British Association, Cardiff.

yield of 17 tons per acre. The average yield of potatoes under farm conditions in England and Wales is a little over 6 tons to the acre, whereas the army gardeners in France produced, from Scotch seed of Arran Chief which was sent to them, crops of 14 tons to the acre. Needless to say, such a rate of yield as this is not remarkable when compared with that obtained by potato-growers in the Lothians or in Lincolnshire, but it is nevertheless noteworthy as an indication of what I think may be accepted as a fact, that the average yields from intensive cultivation are about double those achieved by extensive methods.

The reduction of the acreage under soft fruits—strawberries, raspberries, currants, and gooseberries—which took place during the war gives some measure of the sacrifices—partly voluntary, partly involuntary—made by fruit-growers to the cause of war-food production. The total area under soft fruits was 55,560 acres in 1913, by 1918 it had become 42,415, a decrease of 13,145 acres, or about 24 per cent. As would be expected, the reduction was greatest in the case of strawberries, the acreage of which fell from 21,692 in 1913 to 13,143 in 1918, a decrease of 8,549 acres, or about 40 per cent. It is unfortunate that bad causes often have best propagandas, for were the public made aware of such facts as these they would realise that the present high prices of soft fruits are of the nature of deferred premiums on war-risk insurances, with respect to which the public claims were paid in advance and in full.

I should add that the large reduction of the strawberry acreage is a measure no less of the shortsightedness of officials than of the public spirit of fruit-growers; for in the earlier years of the war many counties issued compulsory orders requiring the grubbing up and restriction of planting of fruit, and I well remember that one of my first tasks as Controller of Horticulture was to intervene with the object of convincing the enthusiasts of corn production that, in war, some peace-time luxuries become necessaries and that, to a sea-girt island beset by submarines, home-grown fruit most certainly falls into this category.

Those who were in positions of responsibility at that time will not readily forget the shifts to which they were put to secure and preserve supplies of any sorts of fruit which could be turned into jam—the collection of blackberries, the installation of pulping factories which Mr. Martin and I initiated, and the rushing of supplies of scarcely set jam to great towns, the populace of which, full of a steadfast fortitude in the face of military misfortune, was ominously losing its sweetness of disposition owing to the absence of jam and the dubiousness of the supply and quality of margarine.

But though the public lost in one direction it gained in another, and the reduction of the soft-fruit acreage meant—reckoned in terms of potatoes—an augmentation of supplies to the extent of over 100,000 tons. Equally notable was the contribution to food production made by the florists and nurserymen in response to our appeals. An indication of their effort is supplied by figures which, as president of the British Florists' Federation, Mr. George Munro—whose invaluable work for food production deserves public recognition—caused to be collected. They relate to the amount of food production undertaken by 100 leading florists and nurserymen. These men put 1,075 acres, out of a total of 1,775 acres used previously for flower-growing, to the purpose of food production, and they put 142 acres of glass out of a total of 218 acres to like use. I compute that their contribution amounted to considerably more than 12,000 tons of potatoes and 5,000 tons of tomatoes.

The market growers of Evesham and other districts famous for intensive cultivation also did their share by substituting for luxury crops, such as celery, those of greater food value, and even responded to our appeals to increase the acreage under that most chancy of crops—the onion, by laying down an additional 4,000 acres and thereby doubling a crop which more than any others supplies accessory food substances to the generality of the people.

In this connection the yields of potatoes secured by Germany and this country during the war period are worthy of scrutiny.

The pre-war averages were: Germany, 42,450,000 tons; United Kingdom, 6,950,000 tons; and the figures for 1914 were: Germany, 41,850,000 tons; United Kingdom, 7,476,000 tons.

Germany's supreme effort was made in 1915 with a yield of 49,570,000 tons, or about 17 per cent. above average. In that year our improvement was only half as good as that of Germany: our crop of 7,540,000 tons bettering our average by only 8 per cent. In 1916, weather played havoc with the crops in both countries, but Germany suffered most. The yield fell to 20,550,000 tons, a decrease of more than 50 per cent., whilst our yield was down to 5,469,000 tons, a falling off of only 20 per cent. In the following year Germany could produce no more than 39,500,000 tons, or a 90 per cent. crop, whereas the United Kingdom raised 8,604,000 tons, or about 24 per cent. better than the average. Finally, whereas with respect to the 1918 crop in Germany no figures are available, those for the United Kingdom indicate that the 1917 crop actually exceeded that of 1918.

There is much food for thought in these figures, but my immediate purpose in citing them is to claim that of the million and three-quarter tons increase in 1917 and 1918 a goodly proportion must be put to the credit of the intensive cultivator.

I regret that no statistics are available to illustrate the war-time food production by professional and amateur gardeners. That it was great I know, but how great I am unable to say. This, however, I can state, that from the day before the outbreak of hostilities, when, with the late Secretary of the Royal Horticultural Society, I started the intensive food-production campaign by urging publicly the autumn sowing of vegetables—

a practice both then and now insufficiently followed —the amateur and professional gardeners addressed themselves to the work of producing food with remarkable energy and success. No less remarkable and successful was the work of the old and new allotment holders, so much so indeed that at the time of the Armistice there were nearly a million and a half allotment holders cultivating upwards of 125,000 acres of land: an allotment for every five households in England and Wales. It is a pathetic commentary on the Peace that Vienna should find itself obliged to do now what was done here during the war—namely, convert its parks and open spaces into allotments in order to supplement a meagre food supply.

This brief review of war-time intensive cultivation would be incomplete were it to contain no reference to intensive cultivation by the armies at home and abroad. From small beginnings, fostered by the distribution by the Royal Horticultural Society of supplies of vegetable seeds and plants to the troops in France, army cultivation assumed under the direction of Lord Harcourt's Army Agricultural Committee extraordinary large dimensions: a bare summary must suffice here, but a full account may be found in the report presented by the Committee to the Houses of Parliament and published as a Parliamentary Paper.

In 1918 the armies at home cultivated 5,869 acres of vegetables. In the summer of that year the camp and other gardens of our armies in France were producing 100 tons of vegetables a day. These gardens yielded, in 1918, 14,000 tons of vegetables, worth, according to my estimate, a quarter of a million pounds sterling, but worth infinitely more if measured in terms of benefit to the health of the troops.

As the result of General Maude's initiative, the forces in Mesopotamia became great gardeners, and in 1918 produced 800 tons of vegetables, apart altogether from the large cultivations carried out by His Majesty's Forces in that wonderfully fertile land. In the same year the forces in Salonika had about 7,000 acres under agricultural and horticultural crops, and raised produce which effected a saving of over 50,000 shipping tons.

IRON INDUSTRY FOR CELEBES.

The Mining Department of the Government of Netherlands India has recently issued a comprehensive report on the possibilities of iron mining and iron and steel manufacture in the island of Celebes, Netherlands India. Government engineers have made extensive preliminary studies and surveys of the entire position, and, according to a report by the United States Consul at Sourabaya, it appears that either the Government or private enterprise will undertake the development of the field in the near future.

The largest ore field to which recent investigations have been directed is that of Celebes in the Larona district, lying near Towoeti Lake. The survey of this field showed 160,000,000 tons of ore, containing an estimated iron content of 5,000,000 tons; and there is believed to be 5,700,000 tons of iron in an additional 210,000,000 tons of ore that have not yet been completely surveyed and tested. This field holds the best promise for early results, since it lies within twenty-five miles of a deep-water bay on the coast, and may be very largely worked by electric power, which can be generated from several waterfalls along the Larona River. The Larona flows from Towoeti Lake to the sea, descending about 300 metres in twenty miles; about 200 metres of the fall occurs within a length of about eight miles. In this distance it will be possible to utilise four falls of approximately 45, 25, 30, and 80 metres respectively. There is also a possibility of utilising other falls of about 25 metres above those mentioned, as well as falls below of an additional 50 to 60 metres.

Computing the natural overflow from the Towoeti, Mahalona, and Matano Lakes, together with the average rainfall draining into the river, it is estimated that 2,610,000,000 cubic metres of water are carried annually by the Larona, or an average volume of 83 cubic metres per second. Having the lakes as natural reservoirs for retaining the heavy rainfall of the rainy season through the dry season, the rate of at least 80 cubic metres per second should be maintained throughout the year. It is then estimated that turbines situated at the four points along the river, and utilising the average flow of 80 cubic metres per second, will develop 144,000 horse-power.

Practically the whole ore field lies on or very close to the surface, the purest ore being on the top, so that the working should be possible at a minimum cost. The ore vein over the entire field varies in depth from 4 to 22½ metres, the average depth, calculated from forty-three widely-separated drillings, being 11·6 metres. The iron content of the ore varies from about 45 to 50 per cent. The average of nine analyses shows the iron content to be 50·55 per cent., while the manganese content is 1·19 per cent., and nickel 0·38 per cent. Rather incomplete analyses as to the sulphur content indicate about 0·14 per cent.

CORRESPONDENCE.

SYNTHETIC DRUGS.

Dr. J. J. Acworth has drawn my attention to an error in my third Cantor Lecture on page 646 of the *Journal* of August 20th. Adrenalin and Epinene raise blood pressure; Ergamine lowers it. Please, therefore, substitute for the paragraph "An artificial drug . . . may be noted" the following:—

"An artificial drug, having much the same action as adrenaline, has been introduced under the name of *Epinene* (3:4—Dihydroxyphenylethylmethylamine, Pyman, *Trans. Chem. Soc.*, 1910, 97, 272); a recent technical synthesis of adrenaline may be noted (Nagai, Brit. Pat. 118298).

"Whereas the blood pressure is raised by adrenaline and epinene, it is lowered by β—Iminazolylethylamine (*Ergamine*, Burroughs & Wellcome)."

J. T. HEWITT.

NOTES ON BOOKS.

HANDBOOK OF COMMERCIAL INFORMATION FOR INDIA. By C. W. E. Cotton, I.C.S. Calcutta: Superintendent of Government Printing, India. 2s.

The author of this extremely useful compilation is the Collector of Customs in Calcutta. Such a work was greatly needed for, as Mr. Cotton observes, "India is so vast and so remote that there is no doubt that on the Continent and in America, if not in the United Kingdom"—where, of course, it is less excusable—"abundant ignorance prevails with regard to the commercial geography of the country and her trade potentialities." The idea of the Handbook was suggested by Mr. Chadwick, Indian Trade Commissioner in London, obviously as the result of his commercial missions to France, Italy, and Russia, as well as of his experience in England. He pointed out that valuable as are Sir George Watt's well-known "Dictionary," and the abridged edition ("The Commercial Products of India"), they are not designed on lines directly helpful to business men, and necessarily omit many details which the foreign trader wants to know. In the case of every important article of Indian export Mr. Cotton has sought to specify the areas in which it is obtainable, the ports from which it is shipped, and the unit of sale and shipment. He deals with the leading ports, including the trading facilities afforded by each, and with the activities of the chief commercial organisations, chambers of commerce, etc. He also gives a conspectus of the different kinds of weights and measures, copies of tonnage schedules, an indispensable glossary of vernacular terms, and a general map of the Peninsula. Every one will share the hope expressed by Mr. Cotton that the ample material he presents to the reader, inadequately described by him as a "bird's eye view" of India's foreign trade, will enable all who are anxious to purchase her manufactures and raw materials to "make larger use of the opportunities which undoubtedly exist for increased trade."

GENERAL NOTES.

CONCRETE TANK REPAIRING.—The *Canadian Engineer* describes a novel process which was successfully employed in repairing two defective sub-surface tanks. The tanks, which were built into the ground, measured 20 ft. in length by 10 ft. in width and 18 ft. in depth. The walls and floors were of reinforced concrete, and were 10 in. thick at the top. The tanks were filled with water, and the surface all round the walls for a width of about 1 ft. was covered with bran. Bran floats for some time in water until it takes a gluish form, when it starts to sink, but very slowly. The sticky substance was naturally drawn towards the holes in the tanks, into which it was forced by the pressure of water. The operation was repeated until the tanks were made absolutely water-tight. The repair was carried out in November, 1919, since when the tanks have not leaked at all.

WHALE OIL PRODUCTION IN NORWAY.—The Norwegian Whalers' Association at Sandefjord reports that the total production of whale oil in Norway during 1919 was 23,654 metric tons. This, writes the United States Trade Commissioner at Copenhagen, is considerably less than the normal output, due partly to the fact that fewer companies were actively engaged in whaling operations, and partly to a number of whaling boats being used in carrying cargo in 1919. During the whole period of the war this industry was seriously handicapped. The amount of whale oil produced by the Norwegian whalers during the years 1908 to 1919, inclusive, is shown below:—

Year.	Metric tons.	Year.	Metric tons.
1908	11,500	1914	95,830
1909	21,500	1915	79,160
1910	30,500	1916	61,170
1911	57,330	1917	38,500
1912	80,000	1918	21,330
1913	100,000	1919	23,654

MOTOR TRADE IN JAVA.—Figures regarding the imports of motor cars and motor trucks into Java during the first five months of this year are quoted in the *Bulletin* of the Federation of British Industries. As was to be expected, America holds a predominant position in regard to this trade. The number of motor cars imported from that country during the period mentioned amounted to 1,075, as compared with 244 from Canada and only 13 from the United Kingdom, while in the case of motor trucks, 377 were imported from America as against 37 from Canada and 22 from Holland. Apparently not a single motor truck was imported during this period from the United Kingdom. As regards motor tyres, Japan heads the list with 19,761, the figures in regard to other countries being as follows:—

America	18,854
France	6,407
United Kingdom	4,971

VITAL STATISTICS OF ENGLAND AND WALES.—The excess of births over deaths in England and Wales in 1920 has up to the present been about three times the average for the corresponding periods of 1917, 1918, and 1919. For the quarter ending in June the births were nearly 100,000 more than a year ago; births totalled 248,665, and deaths 119,283. There is a net increase during the quarter of 160,067 in population, or at the rate of well over half-a-million a year. In view of this rapid increase the steadily growing urgency of the housing problem needs no emphasis. The situation is now probably at its worst, for the few houses that have been built since 1918 are but a drop in the ocean in comparison with the demand.

CANTOR LECTURES.

AIRCRAFT PHOTOGRAPHY IN WAR AND PEACE.

By Captain H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S.

Late Royal Air Force.

Lecture I.—Delivered January 19th, 1920.

THE TAKING AND PRODUCTION OF AEROPLANE PHOTOGRAPHS.

INTRODUCTION.

Aerial photography may be said to date back to the year 1858, when Paris was photographed from a balloon, and though the important developments of the science, as I prefer to call it, during the war had but little connection with pre-war photography from free or captive balloons, we are bound to regard such enthusiastic aeronauts as the Rev. J. M. Bacon, as among the earliest aerial photographers. For it was in the course of balloon photography that the great effect on the ordinary sensitive plate of ground haze, almost transparent to the eye, was noticed, and the advantages of orthochromatic plates and filters were demonstrated. On the other hand, balloon photographs suggested to Laussedat the possibility of surveying and map making by aerial photography, and constituted the medium by which the first aerial surveys were made. But when regarded from the point of view of a camera platform, the aeroplane differed considerably from the balloon, and consequently the apparatus and methods employed diverged rapidly from those of the older aeronauts.

It is sometimes stated that aeroplane photography is entirely a product of the war, but photographs had been taken from aeroplanes before 1914.* It was, however, not generally recognised that the aerial camera was destined to become such an important factor in military operations. And while the possibility of using it for military surveys was contemplated, its advantages as a source of information were scarcely considered.

The earliest work was done before and during the early days of the war, with apparatus and methods which differed little from those of photographers on the ground; but very soon improvements were commenced in every direction. In each of the belligerent countries which had aerial forces, an almost independent development of both materials and methods took place. In material the aeroplane camera underwent a continual process of evolution up to the time of the Armistice, in the course of which every part was affected. Important improvements were made in the plates and filters employed, while the methods of mounting the camera in the aeroplane were concurrently developed. At the same time, the methods of taking aeroplane photographs, and of employing them when secured, were being improved, and for some time the British Army was getting better value from the work done with apparatus which was inferior to that employed by the Germans, on account of the superiority of their methods.

At the end of 1918 aerial photography had become one of the most important sources, if not the premier source of military information; it was carried out by a large *personnel* with highly specialised apparatus. But it must not be forgotten that it is still young though it has been so rapidly developed, and while its applications in war are now well understood its future, as applied to civil purposes in times of peace, is not yet clear. In all probability we shall find that a further process of evolution in methods and apparatus will steadily proceed, and that the aerial camera will become an important adjunct of modern civilisation.

In dealing with the apparatus of aeroplane photography, I do not propose to attempt

* See illustration facing page 188 in "Photography of To-day," by H. Chapman Jones, published in 1913, for an example of pre-war work.

either a description of the modern aeroplane camera or a sketch of its evolution, for which an extensive series of illustrations would be required,* but there are certain features in connection with camera and its employment to which attention may be directed.

Apparatus.

Lenses.—Some misconception has arisen with regard to the lenses used during the war for aerial photography. The lens is, of course, the most important part of the camera, and it is a compound structure containing constituents which are manufactured from different kinds of glass. The essential features of a lens for aerial work are great rapidity, which involves a large aperture or effective lens diameter, and absolute freedom from aberrations. When compared with the lenses used in ground-cameras, those used in the air are generally of long focal length, giving greater magnification with a smaller field of view.

Now, at the outset of the war the supply of suitable lenses available in England was small, though in many cases their quality was excellent. [Some of the best air photos I have ever seen were taken with a pre-war type of lens made by Messrs. Ross and Co., Ltd.] And when we began to require more and more lenses of a type which had not been previously in demand, the British optical firms found themselves in difficulties. It was not so much in the matter of designing and constructing good lenses, but of obtaining the necessary glass which was only manufactured abroad. For a time the R.A.F. was less favourably situated as to the supply of long-focus lenses than either the German or French Air Services, but when the required glass was obtained the British optical firms were in no way behind those of the Continent. The lens-testing section of the R.A.F. photographic service, showed quite conclusively that the lenses with which we were provided were of the highest quality possible, and the oft-repeated generalisation that our lenses were inferior to those of the Germans is quite erroneous. The design and construction of a first-class lens are not simple matters, and should not normally be rushed. British aerial photographs owed much to Messrs. Taylor, Taylor and Hobson, Ltd., and to Messrs. Ross and Co., Ltd., as well as to other firms, for their strenuous and successful efforts to provide the lenses required.

The focal lengths of the lenses used in aerial cameras vary considerably, and the design and construction of the camera, its mounting and method of employment, are generally dependent on the magnification of the lens. The ground to be photographed is always at what is practically an infinite distance from the camera, and consequently the lens is always fixed at the equivalent focal distance from the plate. The scale or magnification of the picture or conversely, the area of ground depicted, can then be calculated by the simple relation. If the plate is parallel to the ground, and at a distance H from it, and if X is the distance between two points on the ground, x the distance between the same two points in the photograph, and F the equivalent focal length of the lens, then

$$\frac{x}{X} = \frac{F}{H}.$$

From this relation it will be obvious that the scale of the photograph increases with F when H is constant, or decreases with H when F is constant. Thus, if photography is done from a great height it will be useful to use a long focal-length lens, or if we wish to cover a large area of ground from a smaller altitude a shorter focal length will be desirable. The choice of a lens is then governed mainly by the type of picture required, and by the minimum height from which it can be taken. In war high flying is usually much safer, and if detail of enemy works, etc., is required, long focus lenses must be used. For topographical survey work over flat country, where small scale pictures of large areas are desired, short focal lengths may be employed In peace times, where lower flying is possible, a medium focus lens will be most useful. The most generally used lenses have focal lengths of between 6 in. and 30 in., though lenses of focal lengths as low as 4 in., and as high as about 60 in., have been employed.

The long focal length lens necessitates, of course, a very long camera, it also results in the portrayal of a comparatively small area of ground, and leads to the employment of the largest possible plate. At the same time it tends to increase the magnitude of focal-plane shutter distortion. On the other hand, the short focal length with a wide angle of view produces noticeable edge distortion in the case of pictures of country which is not absolutely flat.

Plate Size.—The sizes of plates generally employed in aeroplane cameras have been as follows: 5 in. by 4 in. (approx.), 6½ in. by 8½ in., 18 cms. by 13 cms., and 18 cms. by 24 cms. The Germans adhered for the most part to the 18 cm. by 13 cm. size. The English and French

* This work has been attempted by Ives in his book on "Airplane Photography."

Services used the smaller sizes at first, but tended more and more to employ the larger sizes later, especially with long focus cameras.

It is not correct to infer from this that the larger sizes are the best, though they depict a larger area of the ground on each photograph, and consequently tend to reduce the labour of taking, developing, and printing. But they necessitate large and heavy cameras, with heavy magazines, difficult to manipulate in the air, they entail greater possibilities of plate breakage, and probably reduce the linear area which can be photographed though increasing the lateral area. In my opinion, the smaller plates are much the more suitable for survey work, and for aerial photography in times of peace, or when a machine is operating at a considerable distance from its aerodrome. During the war the tendency on the Western front was strongly towards the use of large plates, while on the Eastern fronts the smaller plates retained undisputed superiority.

Shutters.—The great majority of aerial cameras are fitted with focal-plane shutters, which differ considerably in design, more especially as regards the methods of regulating the size of the slit or shutter opening. Some German shutters are of interest because they possess slits with curved sides, so that the width of the opening is greater at the margins of the plate than in the centre. This arrangement may be of value in equalising the exposure given to the plate, because with many lenses the image produced at the centre of the field is brighter than that formed by the marginal rays. In the *Ica* cameras of 1916 the shutter blind was of considerable length, possessing along its course several non-variable slits of different widths; for each exposure that portion of the blind containing the slit of appropriate width was used. Unless the shutter slit is self-closing, an additional safety shutter must be used to protect the plate while the blind is being rewound, and, therefore, a strong tendency has been seen in shutter design towards the slit, which is closed automatically at the end of the exposure and only opened again when the shutter is fully rewound.

It may appear at first sight that the exposure given to the plate in a rapidly moving aeroplane must be very short, or an unsharp picture will be produced; but if t = the exposure time, A = the distance of the ground, F = the focal length of the lens, v = the velocity of the aeroplane, and if d = the maximum space occupied on the plate by a sharp image of a point on the ground (say about $\frac{1}{200}$ in.), then

$$t = \frac{d \times A}{F \times v}.$$

Thus if F is small, say 6 in., and A is large, say 10,000 ft., a sharp picture may be produced from a machine moving at, say, ninety miles per hour, with a comparatively long exposure ($\frac{1}{16}$ sec.). On the other hand, there is great danger of the picture being unsharp, owing to small rotational movements of the camera; but with an efficient mode of mounting the camera there is the possibility of giving longer exposures than might be supposed. If such should prove to be the case, it reopens the possibility of using a sector or other shutter placed in immediate proximity to the lens, should this be of sufficiently small diameter not to introduce mechanical difficulties in the shutter construction.

Objections may be raised to the use of the focal plane shutter on the grounds that it introduces a small amount of distortion into the picture, owing to the travel of the aeroplane during the period when the slit is moving across the plate. The slit may take as much as $\frac{1}{10}$ sec. to traverse the plate, and during this time the aeroplane has moved forward several feet, and consequently, the position of an object near the forward edge of the picture may appear to be farther away from a second object near the rear edge of the view than it should actually be according to optical theory.

Let t = the time of travel of the shutter slit, and V = the velocity of the machine, then the camera moves forward a distance of Vt, while the exposure is being made, and the apparent shift of an object with reference to another point shown at the other end of the plate will be $\frac{Vt \times F}{A}$. With the focal length of 6 in., altitude of 10,000 ft., velocity of 90 m.p.h., and $t = \frac{1}{10}$ sec., an apparent error of ·008 in. may be produced, which is not considerable, and can only become appreciable if carried on through a series of ten or more prints. But if the values of V and F are increased, and if A is kept the same, then the focal plane shutter distortion may have to be allowed for, unless the shutter is so constructed that it moves in opposite directions in successive exposures (*e.g.*, Reihenbild Camera, Mk. IV.). It is well that this shutter effect should be clearly recognised, since it is often urged as an objection to the use of aerial photographs for survey work, and it affords an additional reason for the use of short focus lenses and generous overlaps in this type of enterprise.

Plate Changing.—It was found at an early period that the serial method of taking aeroplane photographs is the best, and this involves the use of an efficient and rapid method of changing the plates. It is not possible to describe here the very large number of mechanical devices which have been used, and the means by which the process has been rendered automatic. With well-constructed apparatus the use of magazines containing plates, controlled by gravity, has proved to be quite satisfactory in the large majority of cases. Whatever the method employed, it is necessary for some types of work, *e.g.*, road reconnaissance, to take a long succession of, say, one hundred photographs at fairly short intervals, without making any break in the series, and the English system of magazines containing eighteen plates, provided an effective means of doing this. It is generally easier to change small plates than large ones, and this may be adduced as an additional argument for plates of the smaller sizes.

Plates and Filters.—The principal considerations affecting the choice of a sensitive plate for aerial use, are :—(1) Colour sensitiveness, permitting effective screening to obviate haze effects ; (2) sufficient rapidity, depending on the light value of the locality and season ; (3) fineness of grain ; (4) good rendering of contrast. Other factors may come in, in war work, especially those concerned with development and freedom from fog. A hard emulsion is also essential to work in hot climates.

The effect of using a suitable filter for absorbing ultra-violet and highly actinic rays of short wave length, may be easily demonstrated by taking oblique photographs with and without the use of a filter. The light haze which is easily penetrated, and almost imperceptible to the eye, apparently scatters and reflects a good deal of ultra-violet light, which has a marked effect on the sensitive emulsion, and without a filter the ground detail is soon lost in mist or haze. This at some localities and periods is very noticeable, and is probably seldom completely absent ; a light yellow screen has a very beneficial effect, and is the type which has been most generally used. The employment of orthochromatic plates is consequently necessary, and the time of exposure has to be increased by an appropriate amount. The German air service was apparently content with plates which were sensitive to light of wave-lengths up to those corresponding to yellow light, but we found that still better results were obtained with plates which were panchromatic, and sensitive not only to yellow but also to red light. Panchromatic plates are produced by the use of dye sensitising substances, and one of the very important achievements of British chemists during the war was the synthesis and production of new and very efficient dye sensitisers for this purpose. The work of Professor Sir W. J. Pope, F.R.S., resulted in the production of a plate which was highly sensitive to red and yellow light, and which was manufactured by the Ilford Company, with excellent results. A greenish yellow filter is used with this plate, which gives very good colour rendering of the green and brown colours generally reflected by the earth and by vegetation.

Plates and Films.—Glass plates are heavy, liable to breakage, and require a complex changing and magazine system. Sensitive emulsion spread on a celluloid base, or negative film has the advantage of lightness and simplicity in changing, and from these important aspects it seems a suitable sensitive material to use in aerial cameras. The earliest film camera seems to have been a French one, designed by Commandant Douhet, but it did not prove very satisfactory. A somewhat similar semi-automatic camera was designed in England and manufactured by Messrs. Williamson and Co., which did some exceedingly useful work on the Eastern fronts. It had, however, certain defects, partly mechanical and partly in the difficulty of getting the film to lie perfectly flat during exposure.

For a time film cameras were dropped, but towards the end of the war a very striking and apparently efficient film camera came into use with the German air service (Reihenbild Kamera), and other English, French, and American models were produced.

The main drawbacks to the use of films are :—(1) The difficulty of getting the film to lie absolutely flat during exposure ; (2) the fact that it seems impossible to sensitise film to red light ; (3) the liability of the film to collect static electric charges during its passage through the camera ; (4) the difficulty of developing, washing, and drying, which necessitates heavy and bulky apparatus and large dust-free dark rooms. Most of these difficulties except (2) and (4), have now been overcome, and it is quite possible that film cameras will at some time in the future largely replace plate cameras. The German Reihenbild camera was interesting, because it took a large number of broad and short overlapping pictures, each

measuring 18 cms. by 15 cms.; these showed little or no distortion, owing to fore and aft tilt, and when mounted together gave a complete picture of a broad band of country; they could be well used for topographical purposes.

Camera Mounting.—In the earlier days the camera was held in the hands of the observer, but very soon it was fixed on the aeroplane. A rigid fitting was found to give rise to unsharp photographs, owing to the prevalence of short period vibrations set up by the engine. With the object of damping these vibrations, various contrivances were used to support the camera, such as stretched rubber shock-absorber, tennis-balls, or rubber sponge. The final method was to translate all the rotational movements into translational movement, which can be accomplished by the use of bell-cranks and springs.

In considering the fitting of the camera into the aeroplane, we should, however, not only consider the question of vibrational movements on the camera, but also the exact position of the optical axis and plate when the machine is flying in the air. It adds greatly to the value of an aeroplane photograph, if it can be used for estimating distances and sizes, and for this purpose the scale of the print must either be uniform in all parts, or vary according to a known relation. To secure this the camera must be maintained with the optical axis within a degree or two of the vertical, or with the axis of the pencil of incident rays arriving at a known angle to the vertical. When vertical photos are being taken, it is necessary to fix the camera with its plate in a horizontal position. This may be done on the ground, so long as the exact flying position of the machine is known; but since the flying position varies with its air-speed, one can never be quite certain as to the correct position for the camera. It is preferable, therefore, especially in the case of survey work, to make the position of the camera adjustable, and to regulate it when in the air at the correct height and speed for the work. It has been shown that when a machine is flying steadily, it is possible to effect sufficiently accurate adjustments, by reference to a spirit level, and consequently an arrangement of pivoted supports and adjusting screws can be used with a level or levels fixed to the camera.

The ideal camera mounting would, therefore, possess a good means of absorbing or neutralising vibration, a means of adjusting the position of the optical axis of the camera, and, in addition, in the case of cameras constructed on the English system, a rotational device or turret, enabling the camera to be turned round in its fitting, would also be very useful.

Oblique Photography is carried out for the purpose of obtaining a view of the ground to one side of the machine, and not directly below it. Such a view gives a kind of panorama of a wide area of country, and it is often convenient to include the horizon in the view. Early oblique photographs were usually taken with the camera held in the hand, but this is not a good method. The camera must either be fixed in the machine, with its optical axis pointing obliquely, or the camera may be fixed vertically, and the rays which enter the lens deflected by use of a mirror or prism by an appropriate amount. The most satisfactory oblique views taken on the Palestine front were obtained by the aid of a reflecting prism, which deflected the rays entering the lens by about 86 degrees. The ordinary camera can be used with very little alteration, except the addition of the prism below the lens, and the relation of the optical axis of the cone of rays to the vertical can be fairly easily ascertained. The only drawback to this arrangement is the loss of light at the reflecting surface, and the possibility of internal reflections.

Experience shows that oblique photographs, taken over country which is not well known, or mapped on a large scale, may be quite useless, owing to the great difficulty in subsequently identifying points or localities on them, for the scale of the view varies according to an unknown perspective relation, and there is no criterion by which to judge the relative distances between the objects depicted. If, however, the angle of tilt of the optical axis is known, together with the distance from the ground of the machine, and the focal length of the lens, the perspective of the view can be calculated with ease. A system has been worked out, in which the spacial relations of a view taken at a certain angle, with a lens of a known focal length, can be expressed in the form of a grid, showing the perspective of imaginary lines drawn at equal intervals apart on the ground. The spaces between these lines would represent different distances on the ground, according to the height of the machine, and provide a convenient and rapid method of making approximate calculations of the distances between objects shown on oblique photographs. This system, however, like many others, is at present only applicable in the case of fairly flat or uniform country.

EXAMINATIONS.

"DAILY SKETCH" PRIZES.

As was mentioned in the Report on the Examinations, 1920, in the last issue of the *Journal*, the Proprietors of the *Daily Sketch*, in order to encourage the study of Typewriting and Shorthand, and to assist in ensuring the supply of efficient and educated shorthand typists, offered a sum of £1,000 in prizes in connection with the Society's Examinations. In the Advanced Stage the prizes amounted to £675, the first prize being £250; in the Intermediate Stage the prizes amounted to £250, the first prize being £60; and in the Elementary Stage the prizes amounted to £75, the first being £10. The total number of candidates was 1,141, divided as follows:—

In Stage III. . .	192 candidates.
,, Stage II. . .	389 ,,
,, Stage I. . . .	560 ,,

In the Elementary Stage the prizes were awarded on the result of the usual March and May examinations without any further test. In the Advanced and Intermediate examinations a number of candidates were selected to compete for the prizes. The final test was held on September 25th, when 25 selected candidates presented themselves, 12 in Stage III., and 13 in Stage II.

The list of Prize Winners is as follows:—

LIST OF PRIZE WINNERS IN STAGE III. (ADVANCED).

	Name.	School.	Prize.
1.	Herbert C. Cock	Pitman's School, London	£250
2.	Asher Simons	,, ,,	£100
3.	Kate A. Stevens	,, ,,	£75
4.	Doris J. C. Clark	McAdam's Institution, Edinburgh	£50
5.	Olive Igle	Cusack's College, London	£40
6.	Laura E. B. Feil	Clapham Business Training College	£30
7.	Florence D. Hall	Pitman's School, London	£20
8.	William G. F. Blois	Cusack's College, London	£10
9.	Constance H. Harrison	,, ,,	£10
10.	Gladys Donnison	De Bear School, Swansea	£10
11.	Frances I. Pittendrigh	Cusack's College, London	£10
12.	Annette P. Mooney	Private Study	£10
13.	Christina M. MacDermot	Technical School, Drogheda	£10
14.	Kate Greenburg	Pitman's School, London	£10
15.	Phyllis L. Watts	Evening Continuation Classes, Worthing	£5
16.	Annie Butler	Municipal High School of Commerce, Manchester	£5
17.	Elsie N. Adam	McAdam's Institution, Edinburgh	£5
18.	Joanna Graham	Remington College, Glasgow	£5
19.	Evelyn M. Aitchison	Towne's Commercial School, Sunderland	£5
20.	Dorothy A. Dimmick	Pitman's School, London	£5
21.	Winifred R. Hearn	Private Study	£5
22.	Lily Rutter	Lower Bebington Evening School, Port Sunlight	£5

LIST OF PRIZE WINNERS IN STAGE II. (INTERMEDIATE).

	Name.	School.	Prize
1.	Arthur J. Lee	Municipal Evening School of Commerce, Manchester	£60
2.	Dorothy J. Allan	Cusack's College, London	£40
3.	Ivy Lee	Technical College, East Ham	£30
4.	Winifred Noot	Technical College, Swansea, and Private Study	£15
5.	Elsie Taylor	Cusack's College, London	£15
6.	Helen C. Leitch	De Bear School, Edinburgh	£15
7.	Marjorie Carr	Ainslie's School, 25, Regent Street, S.W. 1	£5
8.	Gladys M. Leete	De Bear School, Brighton	£5
9.	Mary Johnston	Belfast Shorthand Institute, Belfast	£5
10.	Isabel Seelig	Acton and Chiswick Polytechnic	£5
11.	Gladys M. Cumpstey	Grosvenor Museum, Chester, and Private Study	£5
12.	Anne Fowler	Cusack's College, London	£5
13.	Dinah Beagelman	L.C.C. Hammersmith Commercial Institute	£5
14.	Elsie E. Holder	Private Study	£3
15.	Maude M. Johnson	Pitman's School, London	£3
16.	Gertrude Simpson	De Bear School, Inverness	£3
17.	Ethel M. Adams	Pitman's School, London	£3
18.	Charles Howes	Council Schools, Cadishead	£3
19.	Olive Kirby	The Misses Shafto's Training College, Bromley	£3
20.	Violet R. Cranston	Cusack's College, London	£3
21.	Jessie McIntosh	City of London College	£3
22.	Emmie Reardon	,, ,, ,,	£3
23.	Charles H. Lugmayer	L.C.C. Clapham Junction Commercial Institute	£3
24.	Margaret M. Latto	De Bear School, Inverness	£3
25.	Constance E. Harris	Private Study	£3
26.	Jessie M. McCarmick	Pitman's School, Leeds	£3

LIST OF PRIZE WINNERS IN STAGE I. (ELEMENTARY).

	Name.	School.	Prize
1.	Charles S. Wood	L.C.C. Hugh Myddelton Commercial Institute	£10
2.	Dora C. Mitchell	Cusack's College, London	£5
3.	Dorothy M. E. Horsman	Day Commercial School, Kingston-on-Thames	£5
4.	Beryl W. Braddock	Day Commercial School, Kingston-on-Thames	£5
5.	Marion Frodsham	Commercial Institute, Bolton	£5
6.	Dorothy Newitt	Evander Childs High School, New York, U.S.A.	£5
7.	Catherine E. Hawkes	Day Commercial School, Kingston-on-Thames	£5
8.	Anne C. Edwards	Cusack's College, London	£3
9.	Lilian W. Clarke	,, ,,	£3
10.	Isobel C. McCourtie	De Bear School, Dumfries	£3
11.	Phyllis Crane	Pitman's School, London	£3
12.	Audrey E. J. Werry Easterbrook	Underwood School of Commerce, Portsmouth	£3
13.	Amy L. Townsend	Cusack's College, London	£2
14.	Elsie E. Downer	De Bear School, Brighton	£2
15.	Annie S. Findlay	De Bear School, Liverpool	£2
16.	Nora Moore	De Bear School, Belfast	£2
17.	Gwendoline M. Trolove	Central Classes, Boston	£2
18.	Hulda Kossak	Private Study	£2
19.	Vera B. Schofield	Metropolitan College, Dublin	£2
20.	Emily A. Lisney	Day Commercial School, Kingston-on-Thames	£2
21.	Dorothy Tyler	Technical School, Hanley	£2
22.	Alice Stanley	De Bear School, Huddersfield	£2
23.	Mildred E. Phillips	Day Commercial School, Kingston-on-Thames	£1

Name.	School.	Prize.
24. Margaret Grainger	De Bear School	£1
25. Margaret G. Millar	De Bear School, Edinburgh	£1
26. Dorothy E. Palmer	Handsworth Technical School	£1
27. Gertrude M. Cork	Cusack's College, London	£1
28. Isabella A. Forbes	Devonport High School, Plymouth	£1
29. Annette G. Taylor	Day Commercial School, Kingston-on-Thames	£1
30. Gertrude Berrow	Day Commercial School, Kingston-on-Thames	£1
31. Gladys L. Allden	Day Commercial School, Kingston-on-Thames	£1
32. Gwendolen Hart	De Bear School, Manchester	£1

POST-WAR INDUSTRIAL DEVELOPMENTS.*

By R. E. Graves, C.B.E.,
H.M. Chief Inspector of Factories.

The first year after the cessation of hostilities has been a very notable one for industry, and it is remarkable how complete has been the change over from war to civil production, and with what wonderful smoothness this stupendous task has been accomplished on the whole. The first great step in the transformation was the gradual, and now almost complete, withdrawal of women from the men's industries where they performed such magnificent service during the war, and the absorption into industry of the demobilised men. The next great step was the resumption of the manufacture of the ordinary articles of commerce. In many trades the manufacturers had little difficulty because the articles made were much the same either for war or peace purposes, but in many others which had been equipped specially for the manufacture of war material, new work had to be found and machinery and plant adapted. For example, factories in which aeroplanes were made are now being used for the manufacture of furniture, motor vehicles, wooden toys, etc.; a cartridge case factory is now making household hollow ware; shell-factories are making such things as steam-boilers, locomotives, agricultural tractors, and milk churns; and at a factory where concrete ships were built concrete blocks for house building are now being turned out. One very large armament firm have turned their attention to the making of railway locomotives, marine engines, and boilers.

Without exception the reports refer to the unprecedented demand for commodities of all sorts, and apparently manufacturers generally have booked enough orders to keep them fully occupied for a long time to come. To meet this great pressure they have been reaching out in all directions with a view to expansion, and the demand for buildings and plant of all sorts is only equalled by the general unsatisfied demand for everything. All the reports refer to difficulties in the way of progress, but the following from Mr. Walmsley (Midland Division) is typical as to the position:—

"Many factors have combined to retard progress, amongst which may be mentioned difficulties and delays in transport, reduced hours of labour, labour disputes, and the shortage of raw materials and fuel, whilst the steady and continued increase in prices has made it extremely difficult for manufacturers to enter into contracts of any magnitude. Notwithstanding all these adverse influences and the unprecedented high prices of goods generally, the demand for practically every marketable commodity has probably never been so great. Even in such luxury trades as jewellery, silver and electro plate, the manufacturers have had their stocks completely cleared out."

The shortage of houses and of skilled labour are mentioned by other inspectors as additional hampering factors. . . .

In order to meet the ever increasing cost of production and the scarcity of labour, and to speed up production, there appears to have been, all over the country, a very general conversion of workshops into factories by the introduction of mechanical power. Several of the reports refer to the greatly extended use of electrical power, both for this purpose and also for motive power in large works. Mr. Rogers mentions that in Bristol the supply of current for power has increased from 11,000,000 units in 1914 to 21,000,000 in 1919, and Mr. Wright reports that in the Newcastle-on-Tyne district extensions have had to be made in the public supply generating stations to cope with the increased demand for power, and also refers to the installation in one large iron mill of electrical plant for driving a large reversing rolling mill requiring 2,500 to 8,500 h.p. Mr. Wilson (Northern Division) says its use is on the increase for heating metal furnaces and for welding steel castings.

The following are trades in which developments are specially mentioned:—

Shipbuilding and repairing (S.E., S.W., N.E. and Northern Divisions).—There has been conspicuous growth of the industry on the East Coast of Scotland at Alloa, Burntisland, Kinghorn and Dundee, and an important development at Londonderry, where several thousands of men are now employed in the industry. In the Newcastle district, however, while orders are plentiful and yard space is being increased, there has been a decline in output on the Tyne and the Wear as compared with the years just before the war. This is attributed to several causes (1) the strike in the early part of the year, (2) the shortening of hours to 47 per week, (3) the stoppage of work on Admiralty ships, (4) inadequate railway transport, (5) a natural slackening of effort on the part of the workmen after five years of strenuous war work.

Glass (S.E., Midland and N.E. Divisions).—This industry was developed enormously during the war, particularly in the manufacture of such articles as optical and chemical glass ware and

* Extracted from "Annual Report of the Chief Inspector of Factories and Workshops for the Year 1919." Cmd. 941. 1s. 6d. net.

electric lamp bulbs, which were almost entirely made in foreign countries before the war, and in other branches of the industry, such as the manufacture of bottles of all sorts, and domestic glass ware, further developments are now taking place. One firm in the Midland division who made a very large proportion of the aeroplane gunsights required during the war is now developing the manufacture of lenses for cameras and scientific instruments. In the manufacture of bottles there has been a wide movement towards amalgamation, and several large works have been erected. Mr. Jackson (N.W. Division) refers to "a very marked revival and extension," while Mr. Wright (N.E. Division) says "the installation of automatic machinery promises shortly to revolutionise certain branches of the industry." Mr. Walmsley (Midland Division), while mentioning developments in various directions, says, "Very little progress has, however, been made in improved methods of manufacture, and it is doubtful if under existing conditions of production the trade could successfully hold its own against foreign competition."

The *Hosiery* trade is very brisk, and the starting of new works is mentioned in Derbyshire and also in Scotland and Ireland. With regard to Scotland Mr. Wilson says that employers have been wise in establishing their new premises in districts where employment for females was needed.

In the *growing and de-seeding of flax* in S.W. England there have been interesting developments, due largely to organisation by the Board of Agriculture and Fisheries. In 1914, only a few hundred acres were under flax, and only one scutching mill was known. In 1919, over 3,400 acres were grown and seven or eight scutching and de-seeding factories were at work.

Other trades in which developments are in progress are motor vehicles of all sorts and general engineering in several districts; synthetic dyes and fine chemicals, including increased output of phenacitin, aspirin, and saccharine (N.E. Division), while in the N.W. Division the position of the dyers and calico printers, who were hard hit for want of dyes during the war, has been relieved, to an extent which could not have been anticipated, by the enterprise of firms in our rejuvenated dye-making industry. In the Midland Division a large number of brass articles which were formerly cast are now being made by hot stamping and pressing, and machine moulding of brass is making some headway. A steadily growing trade in the manufacture of magnetos, formerly obtained entirely from Germany, is also reported, and two trades, namely the hearth furniture (kerbs, coal boxes, etc.) trade, and the perambulator trade, are mentioned as giving employment to many disabled soldiers. One firm of perambulator makers has had over 85 per cent. of their work done by one-armed men.

Both the Midland and N.E. Divisional reports refer to amalgamations and co-operative arrangements between firms with a view to increased and cheapened production. Standardisation and specialisation appear to be the order of the day. In this connection Mr. Walmsley specially mentions the stove and range manufacturers and the gun trade. In the latter the movement has been carried very far, a Limited Liability Company having been formed of all the registered members of the trade, "the scheme being designed to benefit all those engaged in the trade by transferring certain processes from factories which are not so well equipped as others, and assigning such work to firms who have specialised in that particular class of work. This Company . . . will interest itself mainly in output and reduction of costs, thus enabling its members successfully to meet foreign competition. A committee of experts has been formed to decide upon patterns and to draw up specifications for various parts." Mr. Law (Sheffield) also mentions the development of mass production in some of the lighter steel trades, and the adoption of labour-saving machinery in the cutlery trade, particularly in the forging of table blades, and the stamping and grinding of scissors and razors.

Mr. Wright (N.E. Division) reports the following interesting developments in industrial research.

The British Research Association for the Woollen and Worsted Industry, having a membership of some 450 firms, was established early in 1919 in connection with the Department of Scientific and Industrial Research. It has already carried out a large amount of useful work at Leeds University and kindred institutions, and it is now about to remove to premises near Bradford where chemical and physical laboratories will be established together with engineering and other workshops. Its aim is to benefit the industry as a whole rather than individual members.

The Glass Research Association with headquarters at Sheffield has come into being more recently. Dr. W. E. S. Turner, head of the Glass Department at Sheffield University, writing recently on the future prospects of the British glass industry, expressed the view that there are three hopeful signs of success: (1) the increased capital now flowing into the industry, (2) the greater interest being taken by British manufactures in the methods employed in the United States, where engineering has been brought into the industry with results of an astonishing character, and (3) the formation of the Glass Research Association. He also mentions indications that manufacturers are beginning to see the need for employing technical skill in the works for the benefit of the firm itself, and that during the last session they have had at the university a large entry of students intending to take either the Diploma or Degree course in Glass Technology.

MESOPOTAMIA.

A report upon the conditions of trade in Mesopotamia during last year has been prepared in the Civil Commissioner's Office at Baghdad, and is quoted in the *Board of Trade Journal* of September 30th.

The great alluvial plain of Mesopotamia, with its 120,000 square miles of area, and its scattered population numbering now some 2,800,000, had before the war no properly equipped seaport, and few means of internal communication except by the rivers Tigris and Euphrates. Even river navigation, especially of the Euphrates, was greatly restricted by narrows and shallows. Ocean steamers which passed from the Persian Gulf up the Shatt-el-Arab depended entirely on their own gear and on native river craft for the landing and shipping of cargo. Now there are at Basra adequate wharves, capable of accommodating deep steamers, fitted up with cranes and laid out with railway sidings. The Port was constructed in order that military operations might be carried on effectively, and now remains for the purpose of commerce. There are 875 miles of railway lines (chiefly of metre gauge). Shargat towards the north, the Persian frontier to the east, and Basra in the south are all now connected with Baghdad by rail. Roads have been improved until many of them can carry light motor traffic, and some few will bear motor lorries. So far, at least, as communications are concerned, the war has wrought a very great and beneficial change in Mesopotamia.

During the last two years there has been a marked increase in the imports into Mesopotamia. In 1919 the goods coming through Basra were valued at 1,399 lakhs of rupees (100,000) against 1,110 lakhs in 1918, and 398 lakhs in 1912. The total import trade for 1919, including land imports into Baghdad, was valued at 1,840 lakhs. The increased importation of foreign goods into the country has been due partly to the presence of troops and the depletion of stocks under war conditions, and largely to the almost complete cessation of imports into Persia via the Caucasus. It is estimated that from one-half to three-quarters of the goods imported by sea eventually find their way into Persia, and it cannot therefore be emphasised too much that the trade of Mesopotamia is closely allied with that of Persia, or with that portion of Persia which can be reached easily by way of Baghdad. Those who seek to supply goods to Mesopotamia should therefore pay as much attention to Persian requirements as to those of the local population.

The values, in lakhs of rupees, of the principal imports during last year were as given below. India during the war gained a firm hold on the market for cotton piece-goods.

	Baghdad.	Basra.	Total.
Textiles	253	704	957
Sugar	22	196	218
Tea	5	60	65
Grain, pulse, and flour	2	63	65
Tobacco	18	46	64
Carpets	42	—	42
Liquors	4	25	29
Cigarette papers and smokers' requisites	3	23	26
Metals and ores	6	19	25
Soap	7	16	23

The values, in lakhs of rupees, of the principal exports during 1919 were:—

	Basra.	Baghdad.	Total.
Dates	217	4	221
Piece-goods	37	494	531
Grain	27	2	29
Wool	15	10	25
Carpets	9	27	36
Sugar	3	77	80
Tea	2	32	34
Spices	½	9	9½
Gum	2	8	10

The annual export of dates may be estimated at about 50,000 tons in cases and 30,000 tons in baskets, etc. Of the 1919 shipments the United Kingdom took 42 per cent., India 28 per cent., and Arabia 9 per cent.

Piece-goods to the value of 529 lakhs of rupees, and almost all the sugar and tea exported in 1919 were destined for Persia.

Wool exports were only 15,150 bales in 1919 as against 27,500 bales in 1918. In 1916 and 1917 there were 13,063 bales and 16,343 bales respectively as compared with 43,290 bales in 1912. The reduction in exports during and since the war is probably temporary, and due to the reduction in the flocks caused by the military demands for mutton.

Barley and dates form the bulk of the export trade in agricultural produce. The area of land under cultivation is capable of enormous extension. The methods of the Arab farmer are primitive though his skill is considerable. All agricultural implements in present use are hand made. There are openings for the simplest as well as for the most complicated agricultural machinery. The Agricultural Directorate offers facilities for trials of new machinery on its central station at Baghdad, and machines which pass the trials can be demonstrated on the five district stations. The results of the trials are awaited with great interest. Agricultural labourers trained in the use of Western machinery are now available.

Openings exist for dairying appliances, grass and wool presses, flour mills and oil mills, and also for artificial manures. Trustworthy vegetable seeds are in demand, and improved varieties of fruit trees command attention.

River conservancy and flood protection are at present more important than irrigation. The Arab will co-operate with the Irrigation Department to bring water to his land, but he is not eager to do hard work on flood banks, of which he does not appreciate the benefit. The bulk of the heavy work on flood protection has now been done, and the task of the future will be chiefly that of maintenance. The Irrigation Department is at present confining itself to small and immediately remunerative schemes.

TRADE PROSPERITY OF CHINA.

Writing in the *Times Trade Supplement* Professor Middleton Smith gives an interesting account of the present position of trade in China.

"It is worthy of some reflection," he says, "that although politically China is in a state of chaos, yet commercially the country was never so prosperous. It is being demonstrated that the real strength of the country lies in the wisdom and enterprise of the business men.

"The politicians, with their many intrigues, have failed to accomplish anything but an increased debt and occasional outbursts of civil disturbance; the business men have been hard at work and have, as the Americans say, 'made good.' Before the war ended the writer stated that only one part of the world could supply what would soon be needed in Europe; that part of the world was mentioned—it was the Far East.

"Mr. Unwin, in his admirable Trade Review for the Imperial Customs Service, tells us what actually happened. 'After a period of uncertainty and hesitation,' he writes, 'the insatiable food hunger of Europe, and the demand for raw materials made itself felt imperiously in all our markets.' That is to say, China has helped Europe since the war.

"The demand will continue. You can smash up a machine quite easily, but it often takes a very long time to repair it after it has been smashed up. The economic machine of Europe, if not exactly wrecked, is in a very different state of working from the smoothly running machine of pre-war days. But China is in an altogether different state. Out here the economic machine is being improved and perfected, and, although the politicians at times do what is equivalent to putting sand into the bearings, yet on the whole the machine works well. It is on very sure foundations. China has resources, vegetable, mineral, and human, of amazing value, and all that is needed to turn them to account is scientific knowledge and proper organisation.

"It is astonishing that there are Europeans who shake their heads about China and prophesy that the people and the country will never change. They both have changed. Commercial history in China is being made at aviation speed. There are figures which prove that the China of to-day is no longer the China of even ten years ago.

"The great demand for the food and other products of China has brought wealth to the traders, and has enriched the farmers and artisans. The silver shower has enabled Chinese merchants and others to start commercial enterprises in the country. There never was such a demand for machinery as has existed during the last few months.

"It is pathetic to think that in China great chances have been lost. The Treasury of the country is empty; in the past all sorts of promiscuous borrowings from Japanese sources enabled the Chinese Government to 'carry on' from month to month. The notes that have been issued from time to time are now worth only a fraction of their face value. Silver is demanded—the 'promise to pay' of the paper currency is regarded with suspicion. But let us be quite clear about one matter. It is only the word of the Governments — Central and Provincial — that is questioned; the splendid integrity of the vast majority of the business men of China remains unchallenged.

"It is remarkable that the trade of China should have shown such great vitality despite the almost complete failure of the Government. Moreover, other influences have been at work which might easily have reacted unfavourably on the trade returns.

"The Chinese have a remarkable word, which is pronounced *Kung*, and which conveys, to the Chinese mind, simultaneously the meanings of our English words *justice* and *publicity*. That is to say, the Chinese believe that justice and publicity go hand-in-hand. But the publicist, in these days, has a great responsibility. Nothing should be written or said that might be likely to upset further the very unstable political conditions of the world to-day. On the other hand, there are certain facts which are so well known that it is useless, perhaps even dangerous, to overlook them. And one of those facts is the Japanese boycott by the Chinese.

"Throughout last year there was, in China, an extensive boycott of Japanese goods, which, in the opinion of experienced observers, is likely to continue. The Statistical Secretary of the Chinese Maritime Customs says that it 'no doubt considerably injured Japanese trade, at the cost of heavy loss and much injustice to Chinese traders, and has served to engender and keep alive feelings of bitterness and resentment on both sides.' Nobody can defend the weapon of the commercial boycott as a lever for ensuring political ends. But the Chinese have always used it, and often with considerable success.

"The state of China's commerce is healthy. But when that great day of settlement comes which will usher in a new era of proper government, the trade of the country will increase enormously. In the past British firms have been sowing the ground. It is probable that each year the harvest of trade will increase. And that is what Britain needs. At the present time, however, there is considerable competition."

THE JAPANESE TOY INDUSTRY.

The toy industry is a comparatively recent development in Japan. Statistics of production prior to 1913 are of very little value, owing to the smallness of the trade then. The production of toys was valued at approximately £1,228,000 in 1913 and had increased to £1,679,000 by 1918. During this period the imports of toys into Japan decreased from £10,000 in 1913 to £6,000 in 1918. The imported toys consist mostly in better-grade mechanical devices, etc., which, although the initial cost is greater, last longer than the domestic article. The Japanese toy is attractive to the eye, but is likely to break or become damaged in a short while. Among the countries from which

toys were imported into Japan in 1913 Germany was first with £6,300. The United States followed with a value of £2,170. The trade with Germany ceased during the latter years of the war, but the imports from the United States increased from £2,170 in 1913 to £5,800 in 1918. This would lead one to believe that possibly there is room for a further development of this trade, especially in view of the increased wealth of Japan and the growing demand for better goods.

The toy industry in Japan is still in the household stage save for celluloid, porcelain, and metal toys of the better grades. Thus the industry is mainly a hand and not a machine trade, which prevents uniformity of product and keeps profits down to a level lower than those offered in other industries. This tends to curtail production through shortage of labour. Even in the making of "factory" toys, which has shown by far the greatest development since 1913, the number of employees is reported to have increased only from 4,692 in 1913 to 7,622 in 1917.

It appears from a report by the United States Vice-Consul at Yokohama that the principal toys made in Japan are of celluloid, porcelain, clay, rubber, metal (tin and nickel chiefly), wood, cotton, and paper. The production of wooden toys in 1918 was valued at £160,700; of porcelain toys, £166,100; celluloid, £450,500; metal, £148,700.

The centres of production are Tokyo for celluloid, metal, and rubber toys, and dolls; Osoka for celluloid, cotton and paper toys, and dolls; Kyoto for porcelain toy tea sets, other porcelain toys, dolls, paper and cotton toys; Nagoya for porcelain and clay toys, wooden toys, etc.; and Yokohama for wooden, mosaic work, and other toys of a similar nature.

The finished articles made in the homes are collected at various depots by middlemen, some of whom also export directly. Manufacturers seldom export direct, except a few of the larger ones who have capital. The industry as a whole seems to be suffering from a lack of ready money, which may account for the non-centralization in large plants, and the poor quality of the products. It is rarely that any large supply of toys of any variety is kept in stock. Toys are mostly made upon individual order from sample, and sold usually upon a thirty days' payment basis.

In addition to the toy factories, a considerable number of factories making celluloid, porcelain and metal products, also manufacture toys.

Owing again to the scattered, household state of the toy industry in the main, it is impossible to estimate accurately the cost of production. However, generally speaking, the cost is 40 to 60 per cent. of the selling price for wooden toys, 80 per cent. for celluloid toys, 60 to 80 per cent. for porcelain and clay toys, and about 60 per cent. for cotton and paper toys.

Selling prices appear to have maintained a fairly uniform level, notwithstanding the heavy blow dealt by import restrictions imposed during 1917 and 1918 by both the United States and Great Britain. Celluloid dolls were the only toys that appreciably decreased in value, the decrease from 1917 to 1918 averaging roughly about 3s. per dozen. On the other hand, mechanical toys showed an average increase in price of about 30 per cent., due probably to the greater skill of workmen employed in their manufacture.

The metal toy trade (mostly of tin and nickel) seems to be in a comparatively prosperous position. Definite statistics as to quantities and sources of metal used are lacking. However, it is probable that no great proportion of the metals imported from the United States have been diverted to the toy industry. At present, celluloid dolls ("kewpies") and other celluloid toys are going to the United States in considerable quantities.

In order to protect the future of the celluloid industry by preventing the export of inferior goods, inspection is made, and the following specific causes are made the basis of rejection of merchandise: (1) Changeable colours or of materials that are not "fixed"; (2) material too thin for the size of the article; (3) defective manufacture; (4) use of fusible or soluble paints; (5) not properly joined with elastic thongs at joints. Infringements or attempted infringements are punishable by a fine of 100 yen (£10) for each offence against the standards set for export goods. However, for those manufacturers approved and sanctioned by the Governors of the various Prefectures, these standards do not seem to be strictly applied; and it is said that, while inspection is nominally carried out for all toys, results are not very noticeable.

The Japanese manufacturer is beginning seriously to study the wants of his foreign customer. However, the margin of profit being small, there is a strong temptation to realize larger returns at the expense of future business. The results of this tendency are somewhat reflected by the fact that the total export of toys from Japan during 1919 was only £1,327,000 against £1,040,000 for the year 1918, when war restrictions were in force in some of the countries. The post-armistice period has not brought the large orders expected; and the small manufacturer, middleman and exporter are being rather hard pressed. Still, this "weeding-out" process is having the effect of improving the quality of articles produced. The industry is becoming centralised, and the future for those remaining in the business is good. Expected competition from the United States, Germany, and elsewhere will probably be met with comparative ease.

For a time porcelain doll heads constituted an important item in exports. However, inferior quality, an earlier predilection to give Mongolian features to the faces, and various other faults, reacted unfavourably. At present celluloid toys are the principal item. Out of a total export of toys from Japan of £1,040,000 in 1918, £226,500 represented the value of celluloid articles. A considerable share of this export consisted of cheap toys for the bazaar trade.

On account of the import restrictions placed on

toys during 1917 and 1918 by the United States and Great Britain, and the loss of trade from Europe—exports to Spain showing the only increase to a European country—the Japanese exporter endeavoured strongly, with considerable success, to get increased trade in China, Hongkong, British India, Dutch East Indies, Peru, Chile, Argentina, Brazil, Egypt, South Africa, Australia and New Zealand.

Generally speaking, concludes the United States Vice-Consul, the Japanese toy industry appears to have a comparatively promising outlook for the future.

PRODUCTION OF GLYCERINE FROM SUGAR.

At the beginning of the war Germany was "swimming in sugar," to use a newspaper expression. Production had been greater than ever; large quantities left from the previous years were still available; and exportation had stopped. One of the ten "war commandments," set forth on bills posted in all railway stations, advised the people: "Use plenty of sugar with your meals; sugar is an excellent food." Certain measures of the Government, however, soon made it impossible for the people to follow that advice, and sugar became scarce in the market, although it was known that stocks were plentiful, for the production of the 1913-14 crop had yielded 2,715,870 metric tons of sugar. Germany had been the leading sugar-producing country of Europe, and yet the people suffered from scarcity of sugar during the war, and were compelled to use honey and saccharin as substitutes. It was supposed that owing to the shortage of fats the Government was trying to conserve the stocks of sugar. However, according to a memorandum prepared by the Research Division of the United States Bureau of Foreign and Domestic Commerce, it now appears that large quantities of sugar which had been withdrawn from human consumption were used in the manufacture of glycerine for war purposes.

The consumption of glycerine in the manufacture of cosmetics and for other purposes, chiefly in the manufacture of explosives, increased enormously during the war, while the supply of the raw materials—fats—was constantly diminishing. It was, therefore, necessary to seek other sources, and sugar was selected, as its chemical structure is somewhat similar to that of glycerine. The transformation of sugar into glycerine was accomplished by the biochemical method. It had been known for a long time that in the ordinary fermentation of sugar with yeast small quantities of glycerine would be produced, amounting to about 3 per cent. of the sugar. By adding alkalis to the liquid in fermentation the production of glycerine was increased. It was found that almost any salt with an alkaline reaction could be used for that purpose. Experiments were made with acetate, bicarbonate, and dibasic phosphate of sodium and with carbonate of ammonia. The yield of glycerine was increased to 12·7 per cent., but the alkaline mash was found to be an excellent breeding place for all kinds of acid-forming bacteria, which would pollute the glycerine. This fault was remedied by the use of sodium sulphite, which acts as a poison to the bacteria of lactic acid and others, but does not, even in large quantities, affect the yeast cells (Saccharomyces). When sodium sulphite was employed as an antiseptic the yield of glycerine was increased proportionately to as much as 23 to 36·7 per cent. of the sugar.

The ordinary fermentation produces not only alcohol, carbonic acid, and glycerine, but also small quantities of acetaldehyde. When the sulphite is added in increasing quantities the yield of acetaldehyde and glycerine increases, while that of alcohol and carbonic acid decreases. The acetaldehyde was used largely for war purposes. The production of glycerine from sugar had a great practical value in war time, according to German writers. The manufacturing process, patented in 1915, was exploited on a large scale, and the production of glycerine exceeded 2,200,000 pounds a month. The invention also possesses an unusual theoretical interest, as it shows how the transformation of materials by bacteria can be influenced by the addition of chemicals. In the words of a German writer, "the biochemical processes open up new prospects for the future, and seem to be destined to provide many substitutes to a people robbed of all raw materials."

Attempts made during the war in Austria-Hungary to produce glycerine from sugar do not seem to have met the success claimed for similar attempts in Germany. Complaint was made by the Bohemian journals of Prague that carloads of sugar had been wasted in recovering negligible quantities of glycerine, and doubts were expressed whether such waste of food could be justified even by the exigencies of war.

OIL FROM RUBBER SEED.

An article in the "Bulletin of the Imperial Institute" (John Murray) discusses in detail the possibility of utilising the large quantity of seed now being produced on rubber plantations. In the early stages of the rubber industry in the Middle East the seeds were mostly used for raising plants for making new plantations, but as there are now at least 1,000,000 acres under rubber trees the quantity of seed available is much in excess of the planting requirements. It was shown many years ago by investigations made at the Imperial Institute that the kernels of Para rubber seeds yield a large amount of oil similar in properties to linseed oil, and that this oil can be used for paint-making and other purposes for which linseed oil is employed, whilst the cake which is left after the oil has been removed from the kernels is an excellent feeding-stuff for live-stock. Until the last year or two, the oil had only been produced on an experimental scale, but at least one oil mill is

now established in Malaya for crushing rubber seeds, and small commercial consignments of the oil have been sold recently in this country and in Marseilles at good prices. Whether it will pay the planter to supply the seeds to an oil mill depends very largely on the cost of collection, a point on which experts differ. In view of the present necessity for the exercise of rigid economy on rubber estates, and of the enormous demand for oils and feeding-stuffs, it is highly desirable that serious efforts should be made to organise the collection of Para rubber seed wherever it is likely to prove at all profitable, and so prevent waste of material which is undoubtedly of considerable value.

NOTES ON BOOKS.

WEST AFRICAN FORESTS AND FORESTRY. By A. Harold Unwin, D.Oec., late Senior Conservator of Forests, Nigeria. London: T. Fisher Unwin, Ltd. 63*s*. net.

The potential wealth of the forests of West Africa must be almost boundless. We have immense stretches of country covered with vegetation of every description, from fast-growing bamboos and soft-woods to such valuable trees as teak and mahogany. For every purpose to which timber can be put, from paper-manufacture and firewood to the finest cabinet work, West Africa provides material in extraordinary profusion. When, however, one comes to inquire into the actual present value of these forest products, one is surprised to find how small it is. For instance, the value of the forest exports of Gambia in 1914 was £658,911; of Sierra Leone, £900,846; of the Ivory Coast, £519,364; of Togo (in 1913), £175,112; of the Cameroons (in 1912), £1,166,539. The main reason, of course, is the lack of means of transport. The great proportion of the most valuable trees grow in regions that are at present quite inaccessible, and not until the country is well opened up will these great sources of wealth be brought within reach of their markets.

But even though, generally speaking, the West African forests remain untouched, in some districts they are already in considerable danger from careless treatment and neglect. Dr. Unwin quotes the case of the Gold Coast, from which in 1913 forest produce in the shape of logs, etc., to the value of £3,327,743 was exported. There seems to be a real danger here that the people of the Gold Coast may kill the goose that lays the golden eggs. There is a strong opposition to the formation of Forest Reserves, which are now generally accepted as the soundest means of securing the safety of forest areas. As Dr. Unwin remarks, "in India, European countries, Canada, Australia, and in the United States it has been proved that only by a central Government Agency that the forests will be properly preserved, both for this generation and the next; therefore, before it is too late it behoves the Gold Coast people to recognise their responsibility to future generations and allow the necessary legislation so that the forests may be preserved and rightly utilised." And, apart from the intrinsic value of the timber itself, the importance of forests as affecting the climate of a country is now very clearly recognised. The author quotes as instances of countries which are now suffering from having permitted the destruction of their forests, Spain and Portugal, Morocco and Mesopotamia, Palestine and a portion of the Soudan, which is only now being laboriously re-afforested by the Forest Department there. Dr. Unwin does well to draw attention to these important matters, for although the forest areas of West Africa are so vast, the sooner they are placed under proper control and so assured against permanent damage the better for all concerned.

The discussion of this question of forest preservation, however, is a mere incident in Dr. Unwin's volume. His main purpose is to give some account of the trees themselves and of the principal work of the Forest Department. When one considers the immense variety of the West African timbers the greatness of the undertaking will be at once appreciated. The work is divided into fourteen chapters, of which the first ten are devoted to separate regions, such as Gambia, Sierra Leone, Liberia, etc.; Chapter XI. deals with the oil beans, seeds, and nuts of the forest; Chapter XII. with the oil palm and palm kernel industry; Chapter XIII. with the forest in relation to agriculture, while Chapter XIV. contains a brief but valuable bibliography of West African forests.

Each of the first ten chapters contains some account of the district with which it deals, and this is followed by a descriptive list of the trees indigenous in that region. A great amount of labour must have been spent on the compilation of these lists; in addition to accounts of the trees themselves short notes are given of their products and of the uses to which they are put. The text is illustrated by over a hundred photographs taken by the author.

Dr. Unwin is to be congratulated on the completion of a most valuable and important volume, which he is qualified to write by thirteen years' service in West Africa in forestry work.

METEOROLOGY. By R. G. K. Lempfert, C.B.E., M.A. London: Methuen & Co., Ltd. 7*s*. 6*d*. net.

During the war meteorology, like many other branches of science, was utilised in planning naval and military operations to a far greater extent than ever before. On land, at sea, and in the air its applications have been widely increased. In a paper which he read before the Society in 1919, Sir Henry Lyons, then Acting Director of the Meteorological Office, explained in considerable detail the necessity for studying meteorological conditions, not only in connection with such matters as naval and air raids, but also in the planning of land campaigns where weather is apt to be an important, sometimes even a deciding factor. In times of peace, also, a knowledge of

the science is of great value. The power of forecasting the weather is important to the agriculturist, for example, who is in a far better position to plan out his operations if he has some idea as to what the meteorological conditions are likely to be within the next few days.

Great advances have been made in the study of this science during the last thirty, and more especially during the last six years. The atmosphere has been systematically explored by means of kites and balloons, while meteorological instruments have been enormously improved. In the present volume Mr. Lempfert describes in as simple a style as is compatible with the complexity of the subject, the main results derived from the new methods of observation. The book will be of great value to the serious student of meteorology, and even to the layman it is full of interest. In his opening chapter the author gives a striking instance of the value of weather maps. He examines in detail a number of maps, and in particular that showing the meteorological distribution on the morning of February 17th, 1915, on the evening of which day two German airships were lost through stress of weather on the coast of Denmark. Had the German authorities been in possession of fuller reports as to the weather conditions in the West, they would no doubt have recalled their ships; or possibly would not have suffered them to leave their sheds at all that day.

The book is illustrated with a number of diagrams and plates, which the reader will find of great assistance in studying the text.

GENERAL NOTES.

American and British Telephones.— Sir William Noble, Engineer-in-Chief to the British Post Office, in the course of a recent address to the members of the London Centre of the Institution of Post Office Electrical Engineers on "Telegraph and Telephone Engineering in the United States," said that while development in telegraph and telephone engineering was practically at a standstill in this country during the war, American engineers had been preparing plans to apply the most up-to-date improvements throughout their system, and to replace their exchange plant in all the large cities by the automatic system. One feature of the American organisation which impressed him most was their unique and extensive provision for research in all branches of telegraph and telephone science, and there was no doubt that America's foremost position was largely attributable to the generous policy which had been followed in that matter. The general introduction of automatic exchange working was probably the main feature in their scheme of progress. Discussing this matter with telephone experts at all the cities he visited, he found practically a unanimous opinion that full automatic working was the only certain method of ensuring the quality of service now demanded by the public. In this country there were at present three types of dials, each with a different scheme of impulses. It had now been decided that all systems supplied for use in Great Britain should, in future, be designed to operate from a dial with an average speed of ten impulses per second, the break portion of each impulse being within the limits of sixty per cent. to sixty-six per cent. of the complete impulse. This would accord with the standard adopted in America. The impression he obtained from the investigations made of the panel equipment and the facilities available were so favourable that he persuaded the American Telephone and Telegraph Company to give him the option of purchasing a 3,500 line equipment of the panel type, to enable British Post Office engineers to be in a position to get down to the details of the panel equipment simultaneously with telephone engineers in America. The Secretary to the Post Office had agreed to his proposal to instal it in London. Arrangements had now been completed to introduce it in G.P.O. South, where it would form the nucleus of a 10,000 line exchange. Mechanical tandem junction working would be as accurate, and nearly as rapid, as full automatic direct junction working. A small departmental sub-committee of the Post Office was now considering the introduction of a mechanical tandem exchange for London. Their investigations, although not yet completed, were so far favourable. The popularity of the telephone in America was, he considered, due first of all to the flat rate, secondly, to monthly accounts, and thirdly, to party line services and the policy of fostering residential lines.

Institution of Petroleum Technologists.— The opening meeting of the forthcoming session of the Institution of Petroleum Technologists will be held at the house of the Royal Society of Arts on Tuesday, October 19th, when Sir Arthur McD. Duckham, K.C.B., M.Inst.C.E., will read a paper on "Coal as a Future Source of Oil Fuel Supply." The chair will be taken at 5.30 p.m.

"Living-in" on Canal Boats.—The question of "living in" on canal boats was discussed in the paper on "English Canals and Waterways," which was read before the Society by Mr. Sidney Preston, C.I.E., C.B.E., on February 18th last (see *Journal* of March 19th, pages 279-88). The Minister of Health has appointed a Committee to inquire into the practice and report whether any alteration is desirable. The members of the Committee are: Mr. Neville Chamberlain, M.P. (Chairman), Mrs. E. Barton (Sheffield City Council and Women's Co-operative Guild), Mr. O. J. Llewellyn (Inspector under the Canal Boats Acts), Mr. T. McKerrell (Ministry of Labour), Mr. H. J. R. Murray (H.M. Inspector of Schools), Mr. Sidney Preston, C.I.E., C.B.E. (Ministry of Transport), and Dame Louise Gilbert Samuel, D.B.E. (Chelsea Borough Council). The Secretary of the Committee is Mr. Arthur Jones, of the Ministry of Health, and communications for the Committee should be addressed to him at the Ministry of Health, Whitehall, S.W. 1.

Journal of the Royal Society of Arts.

No. 3,544. VOL. LXVIII.

FRIDAY, OCTOBER 22, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

INDIAN SECTION.

FRIDAY, OCTOBER 15th; SIR CHARLES C. MCLEOD in the chair. A paper on "British Trade with India" was read by MR. THOMAS M. AINSCOUGH, O.B.E., His Majesty's Senior Trade Commissioner in India and Ceylon.

The paper and discussion will be published in a subsequent number of the *Journal.*

CANTOR LECTURES.

AIRCRAFT PHOTOGRAPHY IN WAR AND PEACE.

By Captain H. HAMSHAW THOMAS, M.B.E., M.A., F.G.S.

Late Royal Air Force.

Lecture II.—Delivered January 26th, 1920.

AEROPLANE PHOTOGRAPHY IN WAR.

The utility of aeroplane photography in war may be considered under three headings:—(1) The provision of information as to the enemy, his works, and his terrain; (2) the graphic record of the results of operations; (3) the production of military maps. The last subject may be reserved for the concluding lecture.

MILITARY INFORMATION.

Modern methods of warfare require precise and accurate information about the terrain occupied by the enemy, and about his works. This is especially the case in trench warfare, where no offensive movement has the slightest chance of success unless preceded by a detailed knowledge of every part of the trench system which is the objective, of all gun positions, positions of reserves, dug-outs, etc. Aerial photography provides the only known method of obtaining the required information with the necessary accuracy. Indeed, it seems impossible to imagine how the war could have been brought to a satisfactory conclusion after trench warfare had been established, without the aid of the aeroplane camera. The supply of intelligence by agents, or by the interrogation of prisoners, has become of less importance than the facts discovered by photography, and it was not only possible to photograph things seen, but to gather details which, while of little intrinsic importance, might give indications of the plans of the enemy. The air photograph not only tells us that the enemy possesses a certain work, but it also indicates exactly the position and size of that work, and enables it to be drawn in on a map or plan.

The appreciation of military information depends on the close study and ability to interpret aerial photographs. In vertical views, which are the most generally useful, the objects depicted on the ground have a quite unfamiliar appearance, and must be studied in the light of knowledge and experience. We are especially helped in understanding their nature by a consideration of the shadows which they cast, and also by the examination of stereoscopic pairs of prints depicting those objects. Successive views taken after intervals of time, or photographs of the same place at different times of day, may greatly facilitate the work of interpretation, and it is often quite unsafe to make a report from the examination of a single photograph.

It is especially valuable in detecting camouflage to use photographs of the same spot taken under different conditions, or at different times of the year, and often the most skilfully camouflaged position has been detected by comparison of a photograph of the work with one of the same ground before the enemy had commenced to alter it. Photographs taken immediately after a fall of snow frequently gave valuable information, for guns generally produce blast marks on the snow which are instantly recognisable.

The information supplied by aerial photographs is often much enhanced, if taken together

with that supplied from other sources. Especially fruitful has been the co-operation with sound-ranging and flash-spotting sections for the discovery of the positions of the enemy's guns and battery positions. It is also necessary to use a system of collating and collecting all evidence from photographs and other sources. This involves the employment of a method for registering the exact position on a print of all points of actual or doubtful interest, in such a way that the position of such points can be communicated to all those possessing copies of the photograph, and that it can be noted for future reference. A system of co-ordinates is employed for this purpose, and polar co-ordinates are more suitable than rectangular co-ordinates. The origin of the polar co-ordinates can conveniently be taken from the marks placed on the negative to indicate compass direction of the view, and this proved an easy and useful method which was generally used on the Palestine front.

The types of information which are required for military operations, and which are furnished by air photographs, are varied. In the first place, we may notice the very essential topographical information, the shapes and extent of hills and valleys, woods, marshes, lakes; the courses of rivers or wadis, the nature of their banks, the presence of bridges or fords; the occurrence of towns and villages, their shape, nature, streets; the presence of gardens or orchards, hedges or walls. It is usually quite easy to ascertain all these points from photographs, especially if we have series of stereoscopically paired prints to work from.

The details of the enemy's works may be ascertained to a considerable degree of completeness. Trenches of various kinds, barbed wire entanglements, listening posts, dug-in shelters, etc., can usually be made out without difficulty. Dug-outs and pill-boxes require more careful search and deduction; breast-works may be distinguished from trenches by the study of the shadows which they cast.

The positions of the enemy's guns were often located without difficulty in the early days of the war, but as time went on, and camouflage methods were devised and improved, the search for gun-positions became more difficult, but seldom fruitless. Gun positions are often revealed by the disturbance of earth, by suspicious tracks to their vicinity, by blast marks, telephone cable trenches, and many other indications. If the locality can be photographed several times, and was taken before being occupied, it is unlikely that the battery will escape observation, and it can be dealt with by our gunners. The positions of machine guns are often more difficult to locate, but they usually have certain characteristics which may be recognised. Trench mortars of the larger sizes can generally be found.

The study of the communication trenches and of the roads, tracks, etc., leading up to the front line, is often of first importance. It not only reveals the position of reserve troops and billet areas, but frequently indicates the division of the front into sectors, and gives a clue to the organisation of the troops who are holding the line.

The study of trench history, and the observation of additions or improvements made in the works, often gives useful indications of the enemy's beliefs or intentions. It may appear that he is devoting much labour to strengthening his works, expecting to be attacked, or on the other hand, he may give evidence that he is contemplating an offensive movement.

The roads and railways leading to the rear of positions must always be accurately known and watched; near these heavy guns may be found, dumps may be constructed, bivouac areas may be established or hospitals placed. In addition to these, a detailed knowledge of both the organisations and the nature of the country is important for aerial bombing operations.

The system of telegraph and telephone communications is sometimes revealed in a remarkable manner by aerial photography, and may give valuable information. On the Palestine front, near Gaza, the Turks or their Austrian gunners constructed shallow trenches a few inches in depth to hold their telephone cables. These showed up very clearly in photographs, and revealed the artillery organisation of the sector, indicating the occupied battery positions, the observation posts, command posts, infantry headquarters, etc. In some cases even air telegraph or telephone lines may be distinguished by the shadows of the poles, or the disturbed or uncultivated ground at their bases, or by the tracks of the linesmen.

The rear organisations are often easy to make out, though their details may not provide more than speculative interest. Railway stations, ammunition dumps, aerodromes, camps, etc., can be studied closely from photographs. In the same way harbours, submarine bases, and docks were often revealed. It is indeed difficult to hide anything from the aerial camera, which is the all-seeing eye of the aeroplane, and which

records the most minute details. Nothing can be really hidden unless underground or within dense woods, or in buildings which have been erected for some other purpose.

This fact has correspondingly influenced the disposition of military objects, and necessitated a very careful study of the principles and methods of camouflage.

Results of Operations.

The second great function of the aerial camera is to record the results of operations, such as bombing or bombardment. After such an operation has been carried out, it is of the utmost importance to know the degree of success which has been achieved, or the exact amount of damage which has been done.

A photograph of an enemy battery position, taken after it had been shot at by our guns, showed where the majority of the rounds had fallen, and enabled the battery to be classed as destroyed, damaged, or uninjured. For such a purpose a photograph is much better evidence than an observer's report. One method of carrying out a destructive shoot upon a position is as follows. The position is photographed and the guns fire about ten to twenty rounds upon it without altering their range, after which a second photograph is taken. Examination of the prints enables the mean point of impact of the shells to be determined with reference to the target, and from this the laying of the guns can be corrected so that the mean point of impact shall coincide with the centre of the target. The correction is applied to the guns, and a large number of rounds are fired without further observation; if the guns are capable of maintaining their accuracy a highly destructive result should be produced. This method was frequently employed by German gunners.

The effects of an intensive artillery bombardment of a trench area are well shown by photographs, and the systematic destruction of the enemy's works was often regulated by this means. Photographs taken before and after a bombardment show in a very striking way the awful and destructive effect of a modern artillery bombardment. Houses, trees, trenches, wire, etc., all disappear under the effects of the shells, and a pitted mass of confused shell-holes is all that remains; subsequent photography may display the efforts which are being made to reconsolidate the position by the occupation of shell craters and their connection by small lengths of trench or shell holes produced artificially. Photography of this description would often precede the final assault of a position following a bombardment, and in such a case speed in obtaining, developing, printing, and despatching the prints to headquarters is most essential.

In almost all operational work the value of photographs is lost if their production is delayed, and our Air Force photographers were trained to despatch prints from a batch of negatives in something like one hour after the plates were sent in. During the Gaza-Beersheba operations of October 1917, the Beersheba sector was photographed daily about noon; the prints were produced, examined by the intelligence staff, and the new positions and latest information drawn up in map form shortly afterwards, this map was copied by photography, and copies of it were dropped by an aeroplane on the headquarters of all units in the field about 5 p.m. on the same afternoon. While there is nothing of particular note about this performance, it serves to give an idea of the way in which aerial photography assists the army, and puts commanding officers in possession of the latest intelligence about the front in a very efficient and rapid way. By this means great precision is gained which is essential to the success of operations under modern military conditions.

The camera is an essential adjunct when aeroplane bombing is being carried out, because it provides a means of ascertaining what damage has been done by the bombs. In the excitement of a large raid, it is almost impossible for pilots or observers to note exactly where their bombs fall, but the photograph not only shows the damage done, but the craters left by the wides. Numerous examples have been exhibited in public showing the results of aerial bombing as indicated by photographs, and among the more striking have been those depicting an attack on an ammunition train, and those showing an attack on a reservoir.

The Relation to Strategy and Tactics.

It has been pointed out above that the aeroplane camera has introduced a great element of precision in the operations of warfare. In the past commanders have usually contested for the occupation of commanding points, from which a view of the opposing forces could be obtained; but the aeroplane has greatly diminished the value of such points, and air photographs give to commanders a very much better view of the enemy's dispositions and terrain than could ever be obtained from the ground. In this way, both strategy and tactics

have been influenced. It is now possible to gain so complete a knowledge of the positions of the enemy that, as is well known, a hostile position can be reproduced behind our own lines, and a proposed attack can be rehearsed in almost every detail. By such rehearsals the plans for the attack are not only perfected, but the attacking troops become so familiar with the position and works before them that they are able to carry out an assault in the dark.

Aeroplane photography, together with sound ranging, has provided a means of combating the efficiency of modern artillery, and by providing a good means of detecting battery positions, they have contributed largely towards the saving of life, for an attack without careful preliminary counter-battery work is a costly business.

Quite apart from the revelation of enemy dispositions, the aerial photograph has helped much in the preparation of the operation orders and plans for an advance. By the aid of vertical and oblique photographs, and especially of stereoscopic views, the lie of the country is revealed. The exposed spots are shown, as is also the position of cover and dead ground. On many occasions commanding officers have testified to the help given by the study of aerial prints in disposing their men.

Another way in which the aeroplane by camera and bombs may have a definite influence on strategy, is shown by the operations of the troops under Field-Marshal Viscount Allenby in Palestine during September, 1918. An attack was arranged and carried out with the object of driving the Turks out of their entrenched positions on the coastal plain, and at the same time cutting one of their main lines of communication by an encircling movement. The Turkish and German reply, which had been previously arranged in event of this movement, was a withdrawal to the hill country, which abounded in natural defensive positions and possessed few roads. This plan was frustrated, and the withdrawal into the hills became a rout and a débacle in the following way. The roads leading through the hills, along which the troops and transport could pass, had been carefully photographed and studied with the aid of the stereoscope. It was ascertained in this way that they possessed certain sensitive portions; on two of the roads there were bottle-neck valleys, where a steep hill-side came down to the road for a few hundred yards on the right hand side, and a stream bed occupied most of the space on the other side of the valley.

As soon as the Turkish retirement was commenced, and the main body of troops reached these points, they were violently attacked by our aeroplanes with bombs and machine guns. Escape was impossible, the road became blocked, and troops and transport from behind came crowding up into the bottle neck, to furnish a fresh target to new aeroplanes which were coming up with their deadly freight of bombs. In the course of a few hours, after undergoing this experience, a Turkish army was entirely broken, demoralised, and ready to surrender. A second army met with a similar fate on another long road, by which it was endeavouring to retire to the Jordan. This road was also known in detail, owing to careful photography; it ran down a valley, and possessed a very vulnerable point at the bottom of a long descent where the road crossed over a stream bed. Here again the way was blocked by the effective bombing of some motor lorries at the crossing, and the troops and transport on the road behind were brought to a standstill, where they remained absolutely at the mercy of our attacking aeroplanes, which wrought frightful havoc among them. This army was practically destroyed, and almost all its transport and guns was captured.

The points of general strategical importance which emerge from this operation are, first, if an army can be forced to retire by a route through a sensitive position, it may be seriously damaged by an attack; and, secondly, that the aeroplane camera provides a means of discovering those points which may be regarded as sensitive, and at which an air attack may best be delivered. Points such as those, which are here called sensitive, may be found along almost any road which runs through hilly country.

In this respect, as in others, the careful photographic survey of the topography of the country—which can be so readily effected by the aeroplane camera, as will be described in the next lecture—is bound to have a great influence on the military operations of the future.

WOMEN'S POSITION IN INDUSTRY AFTER THE WAR.

The "Annual Report of the Chief Inspector of Factories and Workshops for the year 1919" (Cmd. 941. 1s. 6d. net) contains the following observations by Miss A. M. Anderson, C.B.E., H.M. Principal Lady Inspector:—

Any complete summing up of the women's position in industry in 1919 is extraordinarily difficult owing to the presence and working of various contrary

currents, favourable and unfavourable, both to the retention of women and extension of their employment in relation to new developments of trade, and in some instances to their re-settlement in their old industries. These currents have varied in intensity in different parts of the country, and in different branches and groups of industries. The variations naturally affect the conclusions of the Inspectors reporting. Most are agreed as to certain outstanding features: (*a*) that the year must be regarded as a transitional and abnormal year, particularly in the sudden falling away of employment for women in engineering industries, and as substitutes, before large branches of their own work had time to expand; (*b*) that in spite of all the difficulties that had to be encountered in the turnover from war production to civil production, the strikingly unselfish readiness of the women to yield place, even in the work where they had altogether made good, to the returning men, greatly helped to facilitate the transition. "In peace-time industries, where women had been replacing men on well-paid work, the temptation to remain must have been great, and it says much for the . . . women that here, too, they left cheerfully as the men returned" (Miss Slocock). The change back has been effected with far less effort than was the earlier change from civil to war production, and this is largely an effect of the careful substitution agreements of employers and workers made in so many industries under guidance of the Factory Department (Mr. Jackson); (*c*) that many younger employers returning from the war have a new outlook as regards need for fresh methods of production and new vision as regards workers', and particularly women workers', needs. As one said to an Inspector, "We have seen the impossible undertaken and accomplished . . . and now we want to carry on here." The Inspector adds, "Out of the materialism of war there has emerged in individuals a wider spirit of toleration which is very wonderful to watch" (Miss Coombes); (*d*) that friendly as the relations have been in the past between Inspectors and both workers and employers, there is a new eagerness on the part of employers to have frequent visits from the Inspectorate. "I have come across two or three ex-officers starting new ventures expecting an Inspector's visit, and willing to co-operate in what must be a new spirit of comradeship" (Miss Gwynne). "Letters from occupiers expressing thanks for instructions and help given are by no means uncommon" (Miss Escreet); (*e*) that employers are awakening to the need of starting new factories for women's recognised industries in places where employment for women is limited, and instances of hosiery and wholesale clothing factories in new neighbourhoods hitherto lacking women's trades are specially noted; (*f*) that in the later months of the year the supply of labour for the older industries was growing more normal, as wages rose for learners as well as skilled workers, and better conditions for welfare were developed; (*g*) in certain industries, such as the manufacture of corsets, blouses, shirts and collars and cardboard boxes, which were greatly reduced or almost in abeyance during the war, workers being diverted to war industries, there was an acute shortage of skilled labour, due largely to practical cessation of normal training during war-time. On resuming ordinary peace undertakings in such industries, the tendency has been gradually to make up the deficit by training young workers rather than by intensive training of older women.

In discussing the new spirit found in factories amongst employers which "promises well for the future," Miss Martindale refers to complaints that have been made regarding certain indications of slackness on the part of the women. "That a new spirit amongst the women should not be so clearly definable as amongst the employers is not surprising when one remembers what a profound upheaval in their lives the war has caused. During the war women's powers and capacities were called into full play, and no one denies that there was a response beyond all expectation. To-day there is little call to a strenuous and sustained effort, entailing full use of powers and faculties. Instead, interesting work is taken out of their hands, and they are being forced back into the routine of their hitherto normal occupations. Some employers, keen to produce, are not inclined to regard the point of view of the woman employee with much patience, others have grappled with the situation by making efforts to open up new avenues of employment for them" (Miss Martindale).

In a factory employing many young women and girls in new and old processes, most of whom have been munition makers, a capable welfare supervisor observed to me that unquestionably there was at the beginning of 1918 a slackening of energy, due to over-fatigue in the making of munitions and to a mental and physical reaction from the strain of the war. A considerable proportion of the girls had to be sent to convalescent homes to recover health and tone, but by the end of the year returning strength and vitality was noticeable, especially in the girls employed on new lines of work. Here not only were they encouraged to show initiative in suggesting modifications of patterns for the varied articles they were forming in coloured "erinoid," but they were also enabled to attend technical continuation classes and to develop physique by means of drill, dancing and other recreation.

Cotton and woollen textiles, hosiery, boot and shoe, hats and wholesale clothing, stand out amongst all other industries in the demands they have made during 1919, especially in the later months, for women's labour. If more systematic intensive training could have been undertaken in textile factories at the beginning of 1919, of girls of 16 to 20 years, who had in many cases no trade other than munition making, the industries as well as the women would have gained. The shortage of women's labour has been marked

throughout the year as the housing difficulty remains, even though improved wages and welfare conditions have removed part of the earlier obstacles to inflow of labour. "One or two large woollen manufacturers have attempted or considered the provision of hostels, but women do not take kindly to hostel life, except perhaps as a war emergency measure" (Miss Slocock). Limitations to the supply of new machinery and shortage of women's labour are severely felt in the Halifax district, and throughout the West Riding there is a shortage of the very necessary burler and mender. In Huddersfield, accumulation of pieces due to this cause has resulted in overtime beyond the 48 hours week (Mr. Wright).

As regards cotton, in some districts the number of women in the mills is greater than before the war. "In the Burnley district demobilised men are not returning to weaving, and there is therefore a large increase in the numbers of the women employed" (Miss Andrew). "The whole of the cotton industry is booming. Many firms have orders on hand which will absorb a whole year's production. In the weaving branch there is a shortage of weavers and looms are in consequence idle, yet there is talk of new sheds being built" (Mr. Jackson). In the linen textile trades in Scotland, in spite of the great demand, work is hampered by want of flax and shortage of weavers, so that looms are standing idle in nearly every mill (Miss Meiklejohn).

In wholesale clothing, special training factories organised by the Ministry of Labour in Yorkshire have facilitated the drawing in of much-needed women's labour, and manufacturers are taking the women over when they are trained. In the Manchester district the clothing trades have vacancies for many more workers than they can secure. "In the felt hat trade of Stockport there is a notable dearth of trimmers to whom falls the pleasantest work and the highest wages, so far as women are concerned, in the industry" (Miss C. Smith). "In Leicester the hosiery and boot and shoe trades could absorb several hundred more workers if they could be suitably housed, and the Chamber of Commerce have approached the Municipal Authority in regard to provision of hostels" (Miss Escreet). Another flourishing industry employing an increased number of women and girls is the gloving industry in Yeovil, where manufacturers are providing special teaching by a woman of experience (Mr. Shaxby).

Several more or less luxury trades are mentioned by Inspectors as affording a field for increased employment of women, *e.g.*, sweets, cigarettes, jewellery. Production on an increased scale in some places and as a new industry in others, gives fresh or extended employment for women or girls in several useful directions: *e.g.*, de-seeding and scutching of flax in South-Western and South-Eastern England (skilled and fairly heavy work), factory dairying in South-Western England, milk products, household hollow-ware making, pencil factories in Cumberland.

The glass industry is one of those into which women entered in a new way as substitutes during the war, and in which they have necessarily continued to a considerable extent throughout 1919 under more or less emergency conditions, owing to shortage of men and particularly to insufficient boy labour; although in Yorkshire use of automatic machinery is changing the trade, apparently not much general progress has yet been made through development of improved methods of manufacture in careful application of women's capacities to branches of the work particularly suited to them, although in the lighest branches of glass-blowing they appear to have done exceedingly well, *e.g.*, in test-tube making. The interesting provision for Glass Research in Sheffield ought to make future progress in this direction possible.

In the Potteries and elsewhere makers of tiles and sanitary ware and other goods for the building trade are very busy. The numbers of women employed in a considerable number of potteries visited by Miss A. Smith were very little less than during the war, when they were working as substitutes for men.

In the skilled dressmaking retail trades there does not appear to be any expectation of return to conditions at all similar to those before the war. There is complaint both of lack of supply of skilled workers and of decreased demand for production. Thus with the rise in wages there is a movement on one side for occupiers to limit the work undertaken to what they can do alone, or on the other towards going into partnership to reduce expenses. Application of electrical power is extending in the larger dressmaking establishments. Milliners' workshops in the old sense have almost disappeared, outside London and a few of the greater cities, the trade being absorbed by the wholesale producer and distributor.

A certain amount of transference of women's work to changed production has occurred in factories engaged on munition work during the war. For example, one national shell factory is used for manufacture of cardboard boxes; aeroplane and other munition factories have turned to motor-car and cycle production, where women are employed on accessories, or to production of sewing machines, or tin box making, where a few women remain as assistant fitters. Two aeroplane factories have been converted to wooden toy manufacture and to watchmaking and small electric instrument making, in which it was hoped that a large number of women might be employed.

Apart from a few scattered examples of this kind, too little thought seems to have been given by those discharging women, to what might be done in the way of adaptation of work for them or improvisation of training to prevent their unemployment. On the whole, the position is simply that "women have almost disappeared from engineering works" and "the women who were employed during the war in metal-working processes in substitution for men have mostly

gone . . . their places so far as still available are filled by demobilised soldiers and youths. . . . The women have all left the heavy iron trades of South Wales, except a few employed as sweepers at a set of blast furnaces. No women are known to remain as drivers of overhead cranes" (Mr. J. H. Rogers).

One of the women's special trades, the laundry trade, has gone through a difficult year. In the South-Eastern Division the trade has not shared in the general activity of demand, and it has been difficult for occupiers to obtain sufficient work. The great shortage of women's labour experienced during the war has steadily lessened in 1919. Although conditions have already considerably improved in laundries, much has yet to be done to obviate wasteful organisation which hampers development of comfort, safety, and health. "In certain streets there are several very small factory laundries, each with its own boiler and engine, any one of which could probably produce power and hot water for all the laundries in the street, each has its own van, and in each the occupier slaves from early morning till late at night as engineer, stoker, washhouse man and van man. In each the wife is forewoman and sometimes packer, in addition to her household duties, and is far harder worked than any of her women. Co-operation and sub-division of work might be developed with very much less waste of energy and fuel, and one would imagine with much more comfortable lives resulting without reduction of output or income" (Miss Pearson). In a Yorkshire laundry, women have been substituted by disabled soldiers in collar polishing, starching and packing, as well as in the washhouse, and the manageress expressed satisfaction with results.

Whereas in some cases employers have wisely established new factories for women's trades, clothing, textile, confectionery, etc., in localities where there was a surplus of women either through local lack of their trades or a sudden cessation of war industry, on the other hand an acute shortage of skilled women has, for various reasons, been seen in certain industries and places. A new recognition is growing up and spreading of the vital importance of securing well-distributed balance of the sexes for unhampered, healthy development of industry. In certain places, as Mr. H. J. Wilson points out, this lack of balance has assumed an extreme and serious form.

"In areas," he says, "where women's employment predominated, such as in the textile centres, manufacturers cannot, even by advertising and offering all manner of inducements, secure a sufficiency of female workers. It would actually appear that an adequate number of women does not exist to staff the vacancies, at least not in the localities concerned, and owing to the extreme difficulty of securing lodgings, girls from a distance are not attracted. Manufacturers and municipalities, too, are recognising now that unless there is a reasonable balance in the demand for both men and women in any given locality, the industries in the end suffer from a shortage of one or other, and general development and prosperity are impossible. To compensate for this difficulty hosiery factories have been started in mining and other areas where men are predominantly employed, and conversely shipbuilding has been developed in such centres as Dundee and Londonderry and Alloa, where the bulk of the employment was for women. It is obvious that successive generations of young girls, so necessary in the textile trades, cannot possibly be forthcoming if there is not employment for the fathers of families. Yet this fact was not much recognised in the past, and certain centres, such as Dundee and Hawick, are to-day suffering acutely from lack of young women necessary to keep their plant fully occupied. Industries in the past have grown up somewhat haphazard with a tendency for factories manufacturing the same type of article to concentrate in the same town or locality. There were no objections to this so long as the industries concerned gave approximately equal employment to the two sexes. On the other hand, if the demand for one sex predominated there was difficulty in satisfying it unless workers were brought from a distance by rail or tram. This position is marked at present in the following centres in this Division: Dundee, Dunfermline, Hawick, Galashiels, and certain areas in the north of Ireland. On the other hand, in the iron-producing towns there is an unsatisfied demand for men and insufficient local employment for women. Women, however, appear reluctant to leave home and live in lodgings; they prefer local employment, consequently if their services are to be utilised it will be necessary to bring suitable industries to their neighbourhood."

PAPER PULP SUPPLIES FROM CHILE.

Some interesting information concerning the paper pulp supplies of Chile are given in the *Times Trade Supplement* by the *Times* Special Commissioner in Autofagasta.

Chile, he writes, possesses 15 million hectares of wooded land, or about 32,000,000 acres, stretching from the islands of the far south to Central Chile, but gradually thinning out north of the province of Cautin.

When I recently visited these forestal regions I was impressed with the density and extent of the tree-covered areas. They are like wide green seas, filling mile after mile of shallow valleys, extending to the feet and up the sides of the Andean spurs; they are thick with ferns and tangled with wild bamboo (coihue or quila), and among many useful timbers there are quantities of such conifers as the alerce and cypress, together with the Chilean pine (Araucaria) of the mountains, suitable as producers of pulp for paper-making.

Two-thirds of this wooded land must, however, be left out of any consideration of Chilean forests available as the basis of a paper pulp industry.

The northerly areas above Santiago produce only small trees, insufficient for local needs as regards fuel and industry—the thorny algarrobo, of the mimosa family, whose pods supply a tannin similiar to that of the Venezuelan dividivi; the quillay, whose saponaceous bark has a wide sale, and the litre, a small fuel-wood. The wooded areas of the central area show, especially in the well-watered regions of Aconcagua, O'Higgins, Valparaiso, and Colchagua, lingue, rauli, luma, and maitén, some boldo, and native oak (roble), the laurel and luma being found as the south is approached. Below Concepción the woodland is thicker, the trees larger, and in Cautin province piles of logs and planks at every railway station denote the presence of the saw-mills that extend to Puerto Monte, to Chiloé island, and to Punta Arenas. More than half of Chile is unable to supply its own timber needs; it is in the great southerly regions of the alerce, the coihue, and the Chilean pine that vast quantities of wood for industrial use must be sought.

Of such primeval, heavily-timbered country there are about four and a half million hectares, or nearly ten million acres. Immense districts are still untouched for lack of adequate transport, although it should be remembered that the narrow shape of Chile, and the large number of southerly rivers and lakes help to render the problem of transportation soluble. The average width of the country is but one hundred miles; through the long north-and-south valley runs the State railway; and there is an abundance of water power available for industry.

Varieties of Timber.

Forty per cent. of the whole territory of Magallanes is thick with forest; the provinces of Chiloé, Llanquihue, Valdivia, and Cautin are also rich in useful trees. Before the war Chiloé island had begun an export of cypress and luma to the United Kingdom. All the lake country is thickly covered with canelò, coihue, and alerce; the two latter are the tallest trees found in Chile. They have been pronounced, together with the Chilean pine, excellent material for paper-making. Coihue of the "white" variety grows in huge quantities. The alerce is a fine conifer, also growing in extensive groups; it yields a red wood resisting exposure to air and water, is light, elastic, and easily worked. The trunk frequently measures from four to five feet in diameter; under the outer bark is a secondary layer heavily charged with resin. This wood, which is employed in the construction of native boats, obviates the use of tar.

There are no forestal laws in Chile, and in the south the woods are of such extent that cleared ground is considered more valuable; as a result, great areas have been, and are being, ruthlessly burnt to afford land for cultivation. Of late, however, many enterprising landowners have begun to plant woods of spruce and eucalyptus, quick-growing trees that have readily become acclimatised in Chile, as have also the poplar and the willow. Any industrial scheme for the production of paper pulp should include an afforestation plan, or the time will come when even Chile, prodigal with her woodlands, will face the same shortage experienced by many countries to-day. A fine forest region such as this of South Chile has not escaped the attention of industrialists, and several suggestions have been made for the establishment of a paper factory using native pulp, but all have so far come to nothing—probably owing to the war.

Attempts at Development.

A Swedish firm is upon the ground making surveys and experiments. Investigations made by a German group prior to 1914 showed the suitability of the coihue and pine, but subsequent plans fell through. The tentative work of French interests also remains without definite result. There are two or three paper factories in Chile, but the material used is chiefly old paper and rags, with a quantity of imported wood pulp; no fine paper is manufactured, the product consisting chiefly of brown wrapping paper or cardboard.

The Chilean market is, by itself, limited by the small population of the country, paper imports reaching a value of about £500,000; but a paper manufacturer operating on a large scale at such a base of supply would seek world markets, and in face of the present shortage of paper pulp, would have every reason for optimism. Water and water-power, ready access to sea transport, and good if not plentiful labour, are among the advantages to be counted upon; the disadvantages are chiefly connected with the heavy rainfall in regions which sometimes count from 40 to 100 inches in the year, rendering the seasoning and drying of timber difficult. It is scarcely necessary to say that these localities should be ascertained and avoided, and that any investigator should judge by the weather not in December but in July the middle of the wet season.

Prospect of State Support.

Much of Chile's forestal land is in private hands, although undeveloped, and has acquired a value since the south was opened up sixty years ago by European immigrants. There are, however, large tracts still remaining under Government control, and it is towards these that an enterprising industrialist would first look for material. The cordial assistance of the authorities in the establishment of a paper pulp factory could, I am assured, be counted upon.

Chilean forests cannot remain neglected for many more years. When the price of paper has soared to such extraordinary heights, and the world is being searched for new sources of pulp, a great area of such quality commands attention: it is not only great, but one of the greatest available sources of timber supply left to mankind. It is too rich and too urgently needed to escape industrial use. British industrialists who have sought raw

materials all over the earth and who have carried enterprise into both hemispheres should turn attention to this great woodland area before the opportunity has passed.

BRITISH LEATHER TRADE: SUPPLIES OF RAW MATERIAL.*

Unless the demand for leather continues on its present low level there will be a serious dearth of hides. The enormously increased outlay necessary to procure a herd of young cattle, the very much enhanced prices of all feeding stuffs, and the almost universal shortage of money, are all factors making themselves felt in the cattle situation. In our own country cattle which could be purchased for £17 to £20 in pre-war days are realising £60 to £70 every week, with every prospect of the price becoming still greater. The inevitable result will be a gradual diminution in the stock of cattle, and this has already commenced. Many papers commented on the very serious decrease in the total number of cattle in the kingdom, as revealed by the Board of Trade figures for 1919. The frigorifico or packer kill of cattle at the River Plate fell off 22 per cent. in 1919 as against 1918, and the foot-and-mouth disease and floods out there have somewhat depleted the herds. It is estimated that there are 7,000,000 fewer cattle in Europe than before the war. Calves are being killed off to a greater extent than ever before because feeding stuffs are so expensive, and many farmers have not the capital necessary to lock up for months in this way, so that there does not appear to be much likelihood of any improvement in the near future.

There are large numbers of cattle in Asia, Africa, and Australia, and some of these sources have already been well tapped. Hides are imported into this country from Mombassa, China, Java, Sumatra, and India. There are large numbers of cattle in Uganda, Rhodesia, British East Africa, the Sudan, and the old German South-West and East African Protectorates, and the hides of these districts are all available for export. Sudan hides are usually half tanned. The tanning materials employed are native products, which are easily washed out, and the hides are therefore very suitable for chroming. The leather is then very similar to full chrome in suppleness, but grain is poor and drawn. It would be much better to establish collecting stations for both these hides in the raw state and also goats. As we shall note later, there are tremendous quantities of tanned goat skins exported from these regions, and the value of the finished leather would be greatly enhanced if the raw skins were exported to some first-class leather-producing country. The best would then be made of them, and this is very essential in these days of an insatiable demand for the very best, with no outlet for inferior goods.

Large quantities of hides and calf skins have been arriving in this country from Mombassa, the port of British East Africa. The quality of these goods is very good on the whole. At present a difficulty arises in the disposal of the lower grades. It is necessary to take original batches to secure a delivery. These may contain up to 50 per cent. and more thirds and rejections. The better grades, however, are really capable of giving good serviceable leather. The skins are well dried and cured, and there is very little, if any, waste arising from faulty drying. The grain of the best skins is very fine, and such skins make beautiful box leathers, which even if they are not box calf are very little inferior to it. Some of the more enterprising tanners in the country are keeping a close watch on this portion of our Empire, and I understand that some have sent out their representatives to arrange for the collection and despatch of the material from Mombassa.

China exports dried hides, and I have had the opportunity of working on some and inspecting many other parcels. They are mostly well-grown hides, of good, even substance. They are not suitable for sole leather, but are just the thing for dressing leather. They make excellent dull chrome upper leather and combination chrome football leather. Most of them are well preserved, but there are many which have been badly dried, and blister in the soaking-down and liming. It is difficult to estimate the value of parcels of China hides owing to the occurrence of this defect and the uncertainty which surrounds them. It seems to have created quite a bad reputation for these goods, despite the fact that many of them are of excellent quality. Some very choice dressing hides are exported from Java and Sumatra. They are well dried, and yield some choice leathers.

Australia seems to have been neglected by the heavy leather tanners and dressers of these islands; and yet it is no mean cattle rearing country. The total number of cattle in the Commonwealth was over five millions in 1901 and over twelve millions in 1910. Of these five million cattle the larger portion were reared in the Eastern States, Victoria, New South Wales, and Queensland. Besides the cattle butchered for domestic requirements there is a fair-sized canning industry in Queensland and New South Wales. The hides from the Australian cattle are very large, though not of the best quality. Large parcels of box sides were imported into this country last year from Australia. The feetage averaged over 40 ft. per hide, they were well chrome tanned, of very even substance, having been split and remarkably well finished considering the quality of the grain, which was rather inferior. The dressing was somewhat of a revelation, for it is only six years ago that an Australian tanner confessed to me that the quality of their manufacture was very much behind ours.

The last, but not least, source of light hides or kips is our dependency in India.

* Extracted from article by "Prefex" in the *Leather Trades' Review* for October 6th, 1920.

EMPLOYERS AND EMPLOYEES.*

As a rule in speaking on such subjects as Production it is usual to deal first with the machine and then with the man. I think this is reversing the importance of the subject, and so propose first of all to deal with the human side.

It is not necessary to explain why it is needful to deal with this side, although a comparatively few years ago it was of secondary importance. The whole trend of the movement of the world is in the direction of study of the individual and individuals, and Chairs of psychology are springing up at various Universities. Associations, such as the Industrial League and the Industrial Council, now happily amalgamating I believe, are giving serious attention to the various phases of psychological study. This joint Association is, I think, one that should receive every encouragement. Lately the League and the Council have considerably extended their scope by forming branches in various towns, and this gives an opportunity of meeting local labour leaders outside the Conference Rooms, and of discussing views at more leisure than is possible when some particular case is being dealt with.

I do not, however, propose to go deeply into the theoretical side of the question, but to discuss it chiefly as it appeals and appears to a practical engineer dealing day by day with men and materials. As an old chief of mine so truly said when he was giving me my first charge of men after having had charge of the testing and inspection with a large firm: "In the past you have dealt with many intricate questions in connection with material, now I am going to give you a much more complicated job—I am putting you in charge of men." We have all of us given—if often unconsciously—some attention to the subject, for when serving our time we were always considering and studying the state of mind of our "mate" or our labourer, and this was probably the greatest education we had in our shop experience. If we benefited by it as we should have done, we appreciate to some degree the thoughts and aims of those we are now in charge of. I say "to some degree" advisedly, for changes take place in the ideas and ideals of labour, and probably no period has seen so great a general change as that which has taken place in the past six years.

Originally we bargained or dealt with individuals, then with fairly small groups, but now we are often only a unit in a body which discusses matters with the representatives of very large bodies of men, oftentimes of very diverse trades and occupations. I think, however, that it may truly be said that the greatest asset which a man can have in these dealings, whether with an individual or with the whole of a trade, is to have a reputation for fair dealing. This may seem to be a truism, but there are times when an oversight gives him an advantage, if he desire to take the word rather than the spirit as the proper interpretation of an agreement. I do not think that labour disputes the right of the other side to fight hard for what they believe are their rights, and they expect the same consideration to be given to them.

There have arisen during the past few years various systems of getting in touch with labour, and although the general methods are still to some extent heterogeneous, they approximate broadly in the engineering trade to a huge Whitley Council. The organisation of this latter is probably well known to all, and in certain specified trades it is said to be working well in its entirety. I do not wish to deal with it or with the larger organisations in our own industry, but with matters which affect our own individual works, and then to deal with a few other matters which affect labour and work in our shops, which will perhaps be looked upon as details.

I must first of all deal with Shop or Works Committees. The constitution of these is not standardised, and it is questionable if it is really desirable that this should be done. Every shop varies in its physical geography and in the distribution of its labour; the main point is that every employee may be fairly and truly represented, and that the Committees are not only representative but have the confidence and respect of those they represent. As a rule all questions of rates are settled for the firm and the employees by conferences covering larger bodies, but points of classification are sure to crop up from time to time, and it is well if these are, as far as may be, settled for every man on the ground. It is doubtful if it is desirable for any definite intervals to be fixed as the maximum for meetings between the management and the committee: the better arrangement seems to be that they shall be called at any time either side desires. In many cases the whole of the Committee need not attend, but possibly the Chairman or Deputy Chairman, the Secretary and one or two of the members concerned, together with any individual who has special knowledge of the matter under discussion, may meet one or more members of the management.

Some may argue that there is nothing left nowadays for such a Committee to deal with, as settlements are so general, but I believe there never was a time when they were so necessary. Questions with regard to the interpretation of agreements and the putting into operation of awards are constantly cropping up. Points dealing with classification of men and the hundred and one little matters which occur in a works have also to be dealt with. It will be realised that if there is any cause of dissatisfaction in a works on the part of a group of men or even of an individual, there is nothing much worse from a production standpoint, and the time for dealing with it is as near its inception as possible. It may be argued that many points are trivial and will finally clear themselves up, but even if there were not the chance that an apparent triviality might grow into a serious trouble, this is surely not a sound argument

* Extracted from the Presidential Address of Sir Henry Fowler, K.B.E., to the Institution of Automobile Engineers.

when dealing with a bit of grit in the machinery of a works organisation. Not only so, but it can be said from experience that a properly organised Committee will frequently help the management by clearing away misconceptions which will always arise. In this, too, they are infinitely better placed than any management can possibly be. As was put to me at a works I had charge of a few years ago, not a tenth of the complaints raised with the Committee ever came forward, most of them were founded on mistaken ideas which the Committee were able to clear away without any representation to the management. The Committee, too, can be useful in disseminating information with regard to various matters which the firm wishes its employees to be acquainted with. Rumours of change of design, of trouble with material, of cancellation of orders, etc., are always unsettling, and a frank talk with the members will be helpful. My friend and late colleague, Mr. Webster Jenkinson, C.B.E., F.C.A., read on January 28th, 1919, before a Conference of the Industrial Reconstruction Council, a most interesting paper on "The Worker's Interest in Costing (a Factor in Industrial Reconstruction)." In this he dealt fully not only with the necessity of costing, but also with the desirability of enlightening labour more than has been the case in the past as to the state of affairs generally. In times past when shops were so small that the works manager was in the happy position of being able to address each employee by his Christian name, this could be done, and probably was done, by a word dropped here and there. We often sigh for those days when personal contact was possible, and it was felt that each one was a necessary integral part of the concern. Now with our huge shops and systems in management such a personal touch is impossible, but we may keep in contact with this side of our work through our Committees if we will only impress them and through them the other workers that we look upon them as men to be dealt with as men by men, and, as I have said before, that we are out to do a straight deal with them, not only when we want to be pleasant but on every occasion. It is so very difficult to get at the point of view of the other fellow, and we must make every effort to do so whenever possible. We are so apt to persuade ourselves that, because we once worked at the bench for a very few years a good many years ago, we understand what the mass of men feel today on every conceivable subject. I must confess that I was utterly unable to understand the workers' objection to payment by results until I read Mr. Sydney Webb's "The Works Manager To-day" a few years ago. One of my shop friends tells me it is already out of date, but if it is, it makes me more than ever ashamed at having to receive belated enlightenment from one who, according to his own statement, has never worked in a shop in his life.

I would like to refer, too, to the paper given by Mr. F. S. Button, A.S.E., Member of the Industrial Court, at the Manchester Convention of the Industrial League on June 16th last, on "Payment by Results." (Industrial League Journal, July, 1920, page 310.) The discussion on this paper, as well as the paper itself, is extremely instructive. I may be an exception, but I rather think that there are many others who would be glad to get an insight into the mind of labour. If we are to do this by direct contact, we must be willing to reciprocate in every way we can, and we must honestly endeavour to place ourselves in their position. In many cases this may be difficult, for the matter may seem to be so clear to ourselves, that we doubt that there can be any other view of it. Sometimes we read an article which on the face of it seems to be written in all sincerity, and which yet seems to be based on a foundation for which there is absolutely no justification. We could, in fact, probably think of technical articles to which this would apply. If we agree that the writer is sincere, these views, however we may disagree with them, represent the matter as it appears to him, and are therefore of value as showing his mind.

There is a question which naturally at once arises when considering the matters already referred to, and that is, who is to deal with this particular side of labour work? In the past Shop Committees have in their inception proved very successful as long as the heads of the firm have given them their personal attention. In some cases they have failed because for various reasons it has been impossible for this attention to continue with a large concern. In cases even to-day we see the engineering head spending so much of his time on these matters that the saying that "we are ceasing to be engineers and becoming labour administrators" seems to be justified in some instances. In America an effort is apparently being made by the appointment of employment managers of a higher status than some who are working under that name in this country. It has been stated that they should rank at least with the works manager, and it must be self-evident that if they are to deal with all employment questions, they must hold a high position on the staff, for the questions they deal with are of vital interest and importance. They must be in a position to deal with matters directly, unless they involve important principles, or the men will realise that it is futile to discuss matters which have to go to someone else for final settlement. There is in works of any size plenty for such an individual to do, for besides dealing with the Shop Committee he would look after employment generally, welfare work in its widest sense, the training and education of apprentices, and would be the firm's representative at conferences of employers on labour matters, and at joint meetings between employers and labour. One difficulty that is met with at present is that of finding suitable men for such a post. It goes without saying that they should be engineers well conversant with shop work and shop life. Beyond this it is largely a question of personality and character, but having

these three great and essential qualifications, they are all the better for training, and here perhaps the schools and courses of psychology, to which reference has already been made, might help. The whole subject is obviously at present in its infancy, but I cannot help referring to the work which Mr. B. Seebohm Rowntree is doing in instituting lecture courses for managers, foremen, etc., to meet and to hear and discuss various industrial labour problems.

One of the points which has a very direct bearing on the production question is that of "labour turnover." Although in automobile work there is, perhaps more than in any other large engineering industry, a similarity of the operations in various works, yet every man who is employed does not at once come on to full production. The result is that the less labour turnover there is the better. I have recently seen it stated in the *American Machinist*, of July 24th, 1920, page 1041, English Edition, that by studying this question the "turnover" per annum has been reduced by the White Motor Co., of Cleveland, U.S.A., from 63 per cent. to 24·28 per cent., which latter figure compares with an average of 300 per cent. for Cleveland generally. These figures may all seem high to us at the present time. It is true that the automobile industry is largely grouped in centres, but I think that there is no doubt that owing to the housing difficulty there is at present less movement of labour than there was before the war, and than there may be again when the housing problem has been solved.

It may be a very small matter, but it is often found that in a works covering a large area, many of the employees even have only a vague idea of what takes place in other shops than their own. Their wives and children are absolutely ignorant as to the place where the head of the family spends an appreciable portion of his life. Many works could arrange that at holidays their shops should be open to any of their employees and their families who would care to visit them. This was carried out lately in the largest of the works I have charge of in conjunction with the Shop Committee, and great interest was shown.

Another point on which the employment manager will prove useful is in dealing with what is broadly called "Safety First." I think many of us whose works, under section 7 (1) of the Police, Factories, etc. (Miscellaneous Provisions) Act, 1916, which came into force on 1st December, 1917, and who now have a regular ambulance room and attendant, are astonished at the number of accidents which occur and require treatment each day, even if they are mostly trivial ones. These trivial cases if not treated at once may lead to serious ones, and should undoubtedly be dealt with at once, but it is naturally still better if they are prevented altogether. The "Safety First" Council is pushing the question of "Industrial Safety First," and here the co-operation and assistance of a Shop Committee is very necessary.

The subject of the education and training of apprentices has been dealt with from this Chair previously in a masterly manner, but I feel that I cannot refrain from pointing out that the new Act of 1918 imposes on us conditions which require the closest attention if they are not to interfere with the progress of our work. If we are to use labour of 15 and 16, and shortly up to 18, to the same extent as previously, it means that we shall have to increase the number of youths of those ages by about 20 per cent., and this means re-adjustment with ages above those mentioned. The matter is, we know, receiving the attention of the education authorities and of certain groups of employers, and doubtless of individual firms.

There is at present one point with regard to education which is in certain quarters a very serious one. This is the large number of young men who are desirous of entering the industry, and for whom suitable training facilities cannot be found. This condition of things obtained in the Electrical Trade some years ago, but not, I think, to so great an extent for a well marked reason. The motor industry resembles the electrical, as it was, in that it is practically new, and as such offers considerable attractions. The idea of speed also has a fascination for so many young men, and on the top of these attractions we have the results of the war. So many youths upon becoming 18 joined up, and at ages from 18 to 23 have left the army and are looking for training; they probably know how to drive a motor bicycle or a car, and think that this will be a good start towards becoming an automobile engineer. Some had before joining up already started training, and are anxious to go back to their shop. The result of this is that there is over-crowding, and many Appointment Boards, I believe, will not consider applications for training in Automobile Engineering unless the trainee has already obtained a trainer himself. It is difficult to find a solution, for most sides of the engineering profession are in the same state. Were this not so, it might be suggested to anyone desirous of becoming an automobile engineer that little if anything is lost in getting a training in a general engineering works, and entering the automobile side later on. This was done in electrical work years ago, and often-times successfully. There are numerous instances of some of the greatest advances in engineering being made by men who have come in with a fresh, clear mind from some other profession, or changed from one section to another of engineering work. The over-crowding is so great as to be a trouble, and the only solution would seem to be to stretch the capacity to the utmost in all cases. It may be said that we are likely to get more young men trained than can possibly find positions. We must remember the great wastage of this particular type of young man during the war, and although the competition for places will be keen, it is to be feared that it will be some time before we can ever make up our proper complement of well-trained men of character, and without these the country cannot progress.

NOTES ON BOOKS.

A NATURALIST ON LAKE VICTORIA. By G. D. Hale Carpenter, D.M., B.Ch. (Oxon.), Uganda Medical Service. London: T. Fisher Unwin, Ltd. 28s. net.

In 1910 the author of this work went out to Uganda to undertake an investigation into the bionomics of the tse-tse fly, and he stayed there, with a break of about a year's leave, until August, 1914, when he was suddenly called away to do duty with the troops on the Uganda-German frontier. During this comparatively short time he carried out a great quantity of exceedingly valuable work; and in addition to his study of sleeping sickness he was continuously observing not only the entomology of the country (though he is first and foremost an entomologist), but also its various birds, beasts, and fishes, and its human inhabitants. These records are now brought together in a volume which will undoubtedly possess the greatest attractions for all lovers of natural history.

The first two chapters give an account of sleeping sickness, and here we are grateful to Dr. Carpenter for quoting the earliest account of the disease which is known in print. It dates from 1742, and was written by a naval surgeon named John Atkins in a book entitled "The Navy Surgeon." The description of the symptoms might pass muster to-day, but the passages relating to the cause and the cures—among the latter "sudden plunges into the sea" are advocated—show that medical science has travelled some distance since John Atkins wrote.

For forty months Dr. Carpenter devoted his principal energies to an intensive study of the tse-tse fly. For this purpose he lived both on the shores of Lake Victoria and on the uninhabited islands where he could find "ideal conditions for studying *Glossina* unaltered by the presence of mankind and his surroundings." His account of the fly, its methods of feeding, breeding, etc., is of absorbing interest. Unfortunately, it is not possible even to summarise it here, and the reader must be referred to the book itself; but one may state that as a result of his investigations Dr. Carpenter comes to this conclusion: "In order to exterminate sleeping sickness two animals must be kept from each other—the Situtunga antelope from which the fly obtains the Trypanosome, and the fly which inoculates the Situtunga with the Trypanosome." He then proceeds to ask, can the Situtunga be exterminated? and the answer is that it would be almost impossible; but he thinks that a good deal can be said as to the practicability of exterminating the fly. He satisfied himself that by providing very attractive breeding grounds the flies might be induced to deposit their pupæ in the places selected for them, where they might easily be collected and destroyed. Fortunately, the fly is an abnormally slow breeder, and Dr. Carpenter is of opinion that by these means it might, in the course of some years, be exterminated.

Passing from the study of the tse-tse fly, the author proceeds to describe the scenery, climate, and life on Lake Victoria, and he gives an excellent account of a canoe voyage to its southernmost island. His chapters on mammals, birds, and reptiles do not need the apology which he offers for them, for, although they are comparatively short, they are full of first-hand information. In particular, his observations of monkey-life and of their various cries are full of interest.

A valuable section of the book deals with the colouration of insects, and many instances are given of protective warning and mimetic colours. The chapter on *Pseudacraea Eurytus*, one of the most remarkable polymorphic mimetic butterflies, will be read with intense interest by all naturalists. The author's patient observations and the success which rewarded them go far towards confirming the Darwinian theory of mimicry. The story of how he caught and reared "Toby," who ultimately developed into *Pseudacraea terra*, and gave the first proof by breeding that the forms of *Eurytus* known as *tirikensis*, *hobleyi*, *terra* and *obscura* are conspecific, deserves to take its place among the classic tales of scientific discoveries.

OPEN-AIR GEOGRAPHY AND TOPOGRAPHICAL MODELLING. By J. W. T. Vinall, A.R.C.A., and G. Linton Snaith, B.Sc. London: Blackie & Son, Ltd.

The value of drawing as an instrument of general education has been too much neglected in the past. Fortunately many of our best teachers now realise the importance of training hand and eye. Mr. Vinall has helped much to bring about this awakening, and we believe that the present text-book, if adopted by the schools, will do a great deal to train boys and girls in the elements of an art which, apart from its general educative value, is likely to prove useful to them whatever their future sphere of life.

The book is divided into three parts. The first deals with surveying and surveying instruments, starting with simple descriptions of scales and verniers, and working up to exercises on ordnance maps. Part II. deals with Panorama Sketching, and is designed more particularly for the use of army candidates. A somewhat novel feature of this section are the pages dealing with aerial navigation, including the study of cloud forms and fogs. Part III. is devoted to army modelling, work which was often found to be of great use during the war. Mention is made, in particular, of a little model of the Vimy Ridge: "Over this Lilliputian landscape staff officers of high rank pored for hours on end, and officers and non-coms. from the Canadian and British units which were detailed for the assault were coached in their parts on this wonderful model. Much artillery plotting was done over this fascinating plan. It deserves to be placed in some monumental niche, for beyond all question it contributed to a degree which it would be difficult to exaggerate to the splendid victory so often schemed upon its surface."

SLIDE RULES, AND HOW TO USE THEM. By Thos. Jackson, M.I.Mech.E. London: Chapman & Hall, Ltd. 1s. 6d. net.

Modern Slide Rules have become extraordinarily perfect, and as calculating machines they work wonders in the saving of time. They are of the utmost value to all whose work calls for the rapid solution of intricate problems which, without their aid, would call for long and tedious processes of decimal multiplication and division. In construction they vary somewhat with different makers, but the main features are much the same. In this booklet descriptions are given of different types of "Gravet," "Log Log," and some special Slide Rules. The general principles are clearly explained, and a number of exercises are given.

GENERAL NOTES.

GAS FROM STRAW.—A gas obtained by the destructive distillation of wheat and other straw is now being produced on a small scale at the experimental farm in the United States under the control of the Department of Agriculture. According to *The Engineer*, several valuable by-products are obtained, such as carbon residue, suitable for the manufacture of lampblack, potash, phosphates, and nitrogenous compounds. The tar and ammoniacal liquors are similar to those formed by the destructive distillation of coal. The results obtained are held to be sufficient to warrant further large scale investigation as to the possibility of designing a plant to produce the gas in sufficient quantities to allow a farmer to supply light and heat for his house, power for his stationary engines, and possibly for his tractor, from a small individual outfit.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH.—The Department of Scientific and Industrial Research have published, through H.M. Stationery Office, a report submitted by the Canned Foods Committee of the Food Investigation Board, dealing with the methods used for the inspection of canned foods and their reliability for the purpose as applied to canned meats. The report was prepared by Dr. W. G. Savage; it is the first of a series, and deals only with imported material; home products will be considered later. The report deals with the subject under the following headings:—Methods of canning of meat so far as they affect the methods of examination; methods of inspection in England at ports of entry; critical consideration of the reliability of the methods of examination employed. The report of the Inquiry Committee on the Standardisation of the Elements of Optical Instruments, now published for the Department of Scientific and Industrial Research by H.M. Stationery Office, contains the results of investigations made by a Committee which was originally appointed as a panel of the Departmental Standing Committee on Glass and Optical Instruments. Before publication the report was considered at a conference held between members of the optical industry and representatives of the department, and the suggestions then made by the industry were carefully considered by the Inquiry Committee before the final draft of the report was settled. The report is divided into the following main headings:—Unit of measurements; objectives for telescopes; diameters for lenses; prisms for prismatic binoculars; mirrors for sextants; level bubbles and mirrors for viewing bubbles; constructional screws; fine motion screws; metal tubing; screw threads for metal tubing, cells and other fittings; sheet metal and wire gauge; shafts and holes; gear teeth; worm threads and wheel teeth; drawings; designation of the standards. The report also contains three appendices entitled, "On the crossing of screw threads and on the zero of a screw," "on inspection of screw threads," and, "on the influence of errors in the prisms of prism binoculars."

NORTH AMERICAN WHEAT CROPS IN 1920.—The September Bulletin of Agricultural and Commercial Statistics of the International Institute of Agriculture announces that the United States wheat crop of 1920 is estimated at 21 million metric tons (14·5 million winter and 6·5 million spring wheat). The latest estimate of the Canadian crop is 7·9 million tons, while the stocks of old crop wheat in the United States on July 1st were 4·1 million tons. The aggregate North American supply of wheat for the current season is therefore 33 million tons, as compared with 32·4 millions in 1919, and an average of 31·8 millions during the previous five years. These data all include estimates of old stocks at the beginning of July, and indicate that the North American supply of wheat for 1920-21 is apparently much as usual. Farm preparations for the winter wheat crop of 1921 are progressing favourably.

VICTORIA AND ALBERT MUSEUM.—A number of interesting pieces of English furniture acquired by purchase and gift have recently been added to the collections of the Victoria and Albert Museum, and are exhibited in the Galleries of the Department of Woodwork. The most valuable purchase is that of an English side-table with marble top of the date 1730-1740, of walnut wood enriched with carving of the finest quality—a distinguished piece belonging to a type hitherto unrepresented in the Museum. Another important purchase is that of an English arm-chair of the first half of the sixteenth century, carved with linenfold panels and ornament of the Renaissance style. Among gifts should be specially noted a pair of richly carved chairs of the Queen Anne period, given by Sir Paul Makins. Of much interest to visitors, further, will be the Powell Collection of Dolls and Dolls' Furniture presented by Mr. Harry J. Powell, consisting of numerous costume dolls dressed by members of the donor's family between 1754 and 1853, with an interesting collection of models of contemporary furniture and specimens of Leeds pottery.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

INDIAN AND COLONIAL SECTIONS.

The Council have appointed Sir William S. Meyer, G.C.I.E., K.C.S.I., High Commissioner for India, a member of the Indian Section Committee; and the Hon. Sir James Allen, K.C.B., M.A., High Commissioner for New Zealand, a member of the Colonial Section Committee.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

AIRCRAFT PHOTOGRAPHY IN WAR AND PEACE.

By Captain H. Hamshaw Thomas, M.B.E., M.A., F.G.S.

Late Royal Air Force.

Lecture III.—Delivered February 2nd, 1920.

AEROPLANE PHOTOGRAPHY IN TIME OF PEACE.

Although aerial photography has been chiefly developed for military purposes, it can be applied in times of peace for many civil purposes. The chief of these is the production of maps and plans, and the carrying out of reconnaissance surveys in little known regions.

In the first place, we may still regard the air photograph merely as a source of intelligence, and use the aeroplane provided with a camera as a means of exploring countries which are little known and which have not been previously studied and mapped. There are many regions in Africa and Asia about which little is known, and photographs taken from aeroplanes flying over some of them have already increased our store of geographical knowledge by showing the nature of the country, its contours, vegetation, etc. For work of this nature oblique photographs taken without special precautions are quite valuable, and suffice to convey the information sought, when no attempt at map-making is contemplated. It is impossible for an observer, when flying over new country, to take in, remember and appreciate more than the salient features of the ground, while the camera, which misses little or nothing except colour, records all the details and is an essential adjunct to aeroplane exploration.

I have given elsewhere a few examples of the value of aeroplane photographs for scientific purposes.* They are especially useful in the domain of physical geography and geology in connection with the investigation of river development, erosion phenomena, and the main features of geological structure. The photography of the basin of the River Jordan has revealed many points of interest in its history. The recent changes in its course are often indicated; the terraces formed during past centuries as it has gradually deepened and altered the river bed, the deposits formed in the old lake which once filled the Jordan Valley, the water courses which in former ages drained into the valley but are now dry, are all distinguishable. Again, the connection which existed between the Jordan Valley and the drainage of Central Syria has been indicated, and the gorge through which the rivers from the Lebanon formerly flowed into the Jordan Valley has been disclosed.

The distribution of vegetation is often very clearly shown in air photographs, the extent and distribution of woodlands is brought out, and several types of woodland can be distinguished by their characteristic appearances. In the same way, several different types of agricultural crops can be distinguished, and areas under cultivation can be readily ascertained. Experiments were made during the spring of 1919 in India, with a view to testing the utility of aeroplane photography in crop surveys, and the results obtained have, I am informed, given very great promise, and disclosed

* Nature, vol. 105, p. 457, 1920.

the fact that by this means the exact area under cultivation with certain crops can be very rapidly estimated.

Archæologists may sometimes be greatly assisted by air photographs which often, in the case of ruined buildings and sites partially overgrown by vegetation, display the plans and arrangement of buildings, in a way which it is impossible to see by observations made on the ground. In the case of the ninth century ruins of the city of Samarra in Mesopotamia, the views taken from above heaps of earth and rubble, which were apparently formless when seen from the ground, gave the outlines and plans of streets and buildings in a most striking manner.*

But there is quite a different aspect of aerial photography for civil purposes, which is the use of air photos for the construction of maps and plans. This was not a new idea, for some work had been done before the war in France, Austria, and Russia, with photographs taken from balloons; but the conditions under which aeroplanes had to work were so different that entirely new systems were needed. During the war a good deal of mapping work was carried out, but the conditions and requirements on the different fronts were not the same, and consequently several slightly different systems of work were evolved. On the Western front, the work of obtaining suitable photographs was one of the most difficult and dangerous tasks which the airman was called upon to perform; but the map compiler had much information and material from previous surveys and from cadastral plans to help him to make the utmost use of the photographs. In the Eastern theatres, on the other hand, it was possible to take photographs of exactly the kind needed with comparative ease, but here the map compiler had the most meagre information from previous surveys.

In order to compile a map of a large tract of country, two distinct types of work have to be done. In the first place, the exact positions of a number of conspicuous points have to be fixed geographically with the greatest possible accuracy (trigonometrical survey), and then topographical details, such as river, hill and valley shapes, have to be drawn in their correct positions round the points whose positions have been first established (topographical survey). The aeroplane photograph can, at present, do little or nothing to help in the first process, but is very valuable in the second stage of the work, for pictures of large areas of country can be obtained very easily in a short time. The photograph itself cannot be regarded as a map, and it is not correct to speak of an assemblage of photographic prints as a photographic map, but over a small area the photograph may be regarded as a plan of the ground by means of which the details can be measured up and, after applying the necessary corrections, can be drawn in on the final true map.

A photograph of the ground is a representation which bears a mathematical relation to the original surface photographed. If all the optical constants are known, such as the distance of the camera from the ground, the focal length of the lens, the angle between the plane of the plate and the plane of the ground, etc., then by measuring the photograph we can draw a true plan of the ground depicted. Some of these constants may be easily found, others may be more difficult to determine, but time will not allow me to deal with them in detail. If, however, the picture represents the ground in a uniform manner, and has the same scale in all parts, and if we can find out what is the relation of the sizes of the objects shown in the picture to their true sizes on the ground, we can at once proceed to draw our topographical detail on the map.

We know that if we use a lens which is free from distortion, we can obtain a perfectly true photographic copy of a picture or plan with a copying camera, so long as the original is perfectly flat, and the sensitive plate in the camera is parallel to it. Also the size or scale of the copy will depend on the focal length of the lens used, and on its distance from the original.

If, however, the sensitive plate is not parallel to the original, the copy will not be true to scale, but one side will be more highly magnified than the other. The more the camera is tilted, the greater will be the discrepancy in scale between the two sides of the picture, and when the plate is put at right angles to the surface photographed, as in the case of a landscape taken from the ground, the objects of the foreground have a certain size, while those of the far distance have become infinitely small. The same principle applies in the case of aerial photography: if the ground is flat, and the plate in the aeroplane camera is held perfectly horizontal, then the photograph shows the ground in true plan. If, however, the plate is tilted at the moment of exposure, one side of the picture will have a larger scale than the other. It may be spoken

* Geographical Journal, vol. 53, p. 330, 1919.

of as an oblique or perspective view if the tilt is intentional, but if the tilt was unintentional and the true plan was required, the tilted view may be described as distorted.

It is by no means easy to take a photograph from an aeroplane with the plate absolutely horizontal, especially when the machine is under anti-aircraft fire, and one of the first steps was to find out methods for transferring to the map, details from a photograph which possessed a slight amount of distortion. There are several ways of doing this, the best being the method of re-photographing in such a way as to correct the distortion by reference to known points shown in the view. This process, however, can only be used when four, or in certain cases three points which are shown on the photograph have been previously fixed by reference to ground survey. In the Eastern theatres of war it was very seldom that this condition was fulfilled, and it was necessary therefore to adopt an entirely different method of work; in fact, it often happened that the only points fixed by ground survey were four or more miles apart, and might be only shown in one print of a series of three or four.

The work done on the Palestine front, where about 2,000 square miles of country was photographed to supply the topographical detail for a new series of military maps, probably shows one way along which aerial photo surveying is likely to develop in times of peace. Here the chief effort was concentrated, not on the methods of correcting distortion, but on the means of avoiding it. If the plate can be maintained in a position not more than one or two degrees away from the horizontal, distortion will be absent, or so small that it is negligible, and still better accuracy may be obtained by taking photographs with liberal overlaps and discarding the edges near which the inaccuracies in scale become more pronounced. The methods used in this field have been described in a recent number of the Geographical Journal,* and need not be here repeated.

Another method of getting over the difficulty of the tilted plate has been employed. This consists in the attempt to measure the angle of tilt at the moment of exposure, and many German cameras were provided with a small optical apparatus actuated by gravity for ascertaining the tilt in the two directions at right angles to the plate's surface. The application of this idea makes it possible to use oblique photographs as well as vertical ones for map construction. The oblique view usually embraces a much more extended area than the vertical photo, but the plotting on the map of topographical detail from it is at present a somewhat laborious process. We must notice, however, that the horizontal plate method is inapplicable in mountainous country, and it is often in country of this description that aerial photography will be most valuable as a survey method in the future. It seems probable, therefore, that the method of working from perspective photographs is one which will amply repay for its study and investigation. Work has been already done on these lines, for it was from oblique rather than vertical photographs that the first balloon surveyed maps were made, and more recently investigators such as Burchall* have returned to this study.

The geometrical and optical conditions of the problem are well known, but the present need lies first in devising a method which will be easy to work, rapid and accurate, and secondly, in perfecting the apparatus for the purpose.

The application of the method of oblique photography also holds out the possibility of extending a survey area away from the trigonometrically fixed base. Assuming that certain points shown in the photograph have been fixed by ground survey, it may be possible to determine accurately the positions of other points shown in the view, and by making fresh exposures to include the spots thus treated, it is, perhaps, possible to determine the position of a third set of points at a greater distance. No practical work has yet been done in England on these lines, but they are probably applicable to the survey of mountain regions, following on the lines of the photogrammetrical methods elaborated in France and America.

It is in country which is difficult of access that aeroplane surveys are most likely to be valuable, and photography from airships must also be taken into account. In some parts of the earth which have not yet been mapped, the main difficulty is that of progression; in parts of the desert mountains of Sinai, as in other similar localities, the ground is so steep and so broken that a party working on the ground could at times do little more than a mile or two per day. In forest regions, work by the ordinary methods of ground survey is rendered practically impossible by the trees and undergrowth, and map-making is very difficult if not impossible. In waterless desert regions again, the maintenance of a survey party, for a period long

* Geographical Journal, May, 1920, p. 349.

* British Journal of Photography, vol. 67, p. 434, 1920.

enough to allow any extended area to be covered, is rendered almost impossible owing to the water difficulties. In all such the aeroplane or airship, which can travel a hundred or more miles from its base and photograph the surrounding country, may possibly be able to achieve surveys of the most valuable description. At present, however, such work must be combined with ground observation whatever may be possible in the future, but a rapid traverse of the country by the easiest route may be sufficient to provide a chain of fixed points on which the photographic work may be fitted. We are as yet only on the outskirts of the problem, and there are many methods by which the range of usefulness of aerial survey may be extended. For example, in a clear sky an aeroplane or airship may be followed by observers through high-powered theodolites for a very considerable distance, and by means of two instruments at either end of a measured base and a wireless apparatus, the position of the machine at any moment may be determined with accuracy. Consequently also the positions of those places on the ground which are being photographed at the times when the observations are made, may also be ascertained. It is difficult to say to what distance work may be extended by this method after suitable apparatus has been constructed including, perhaps, the use of the principle of the heliograph.

We are also only on the threshold of the system of using to their fullest extent the principles of stereoscopy for metrical purposes in aerial surveying. The geometry of the subject has been very fully studied and worked out by M. Clerc,* but the practical and quantitative value of the methods is still awaiting further experiment and investigation.

The employment of aerial survey for mapping the congested cities of the East was successfully introduced during the war, and further experiments conducted more recently bear out the contention which has been made for this work. While city surveys on the ground require in many places an immense expenditure of time and money, they can be carried out from the air in a day or two at a trifling cost. Even if an aeroplane has to be brought up specially for the work, the whole cost of producing a map good enough for police and administrative purposes, is probably not more than a tenth of what a similar map would cost to produce by ground survey, and it can be subsequently improved with comparatively unskilled labour by the usual methods, if a complete ownership map is required.

* Applications de la Photographie Aérienne, p. 53, Paris, 1920.

The preparation and revision of cadastral plans is another activity in which aerial survey promises to play a useful part.

The fact that in an aerial photograph of the sea, lakes, or rivers, there are clearly shown shallows, sand-banks, and rocks near the surface, has suggested the employment of aeroplanes or seaplanes for the charting of harbours or navigable channels. In regions such as the River Hoogly, where changes in the channels are frequent and form a deadly menace to navigation, the use of the air-camera reconnaissance is almost certain to become, in the course of time, an important factor in adding safety to navigation and assisting the development of trade. There are many rivers whose courses change or whose sandbanks alter from time to time, and we now have a means by which such changes may be watched and recorded for the benefit of civilisation, and which will assist man in his contest with the elements. Already our methods have been employed for hydrographic work, and so are assisting the world's navigators.

Enough has been said to indicate the utility of aerial photography in the service of man in times of peace. I have left out of account work of more or less private or limited interest, such as the photography of buildings in our own country, or of estates or golf courses. These may in time come to be regarded as part of the ordinary amenities of civilisation, and air photos may take an officially recognised place as records of the extent and position of grounds or buildings in commercial or legal transactions. The work of carrying out this class of photography has already been commenced by one of our enterprising aviation firms, and the demand which has been experienced shows that a useful result is being achieved.

At the present period the development of the science for civil purposes may be slow, but when the conditions of aviation become stabilised we are certain to see important developments. Later, also, we may expect that countries which are maintaining air forces with a view to military eventualities, will begin to employ machines for peace purposes such as air-surveys, which are of public importance. Thus the arts of war may be turned to account for the benefit of civilisation and the cause of peace.

Many volumes have been published upon the interpretation of aeroplane photographs during the war, but these are confidential publications not available to the general public.

COAL AS A FUTURE SOURCE OF OIL SUPPLY.

Sir Arthur Duckham, K.C.B., M.Inst.C.E., recently read a paper on the above subject at a meeting of the Institution of Petroleum Technologists. He submitted that the industrial future of this country lies in the conversion of coal at the pit's mouth into liquid and gaseous fuels. Liquid fuel, he said, will be recognised as the medium for providing energy for all transport on land, sea, or air, with the exception of electrical transport for congested areas, while gaseous fuel will be used direct for the great majority of heating purposes and for the generation of electricity, either by means of steam plants or engines.

The submarine has become so great a danger that should another war come, it is possible this island might indeed be isolated and cut off from all outside sources of oil supply. It is therefore essential for national as well as economic necessity to develop supplies of oil fuel at home.

The Government, he maintained, instead of appointing Electrical Commissioners should have appointed Heat, Power, and Light Commissioners, to foster fuel conservation on general lines, and not think only in terms of electricity. He trusted that the duties of the Electrical Commissioners would be extended by the Government to embrace these other duties. He reviewed the various processes for the heat treatment of coal, and in conclusion formulated a system of manufacture to meet the demand for liquid and gaseous fuels for practically all purposes. The total gasification of coal is essential, preferably in one vessel. The plant must be economical in first cost, and low in labour charges, but above all the maximum amount of the volatiles in the coal must be recovered in a liquid form, being distilled over at such temperatures and in such a manner that a minimum of cracking takes place. The gas afterwards should be stripped of all saturated hydrocarbons and supplied to the consumer constant in heat value and specific gravity.

Further, special care must be taken to preserve the ammonia obtained from the nitrogen in the coal. The plant must be designed to work with any coal, but he does not believe it possible to design a plant of this type capable of working greatly varying coal over short periods, or of working coal containing, say, over 60 to 70 per cent. of fines.

The form of plant he suggests is one or more vertical retorts superimposed over a water gas producer, the retorts being so constructed and heated that even difficult coals like Durham will work through without undue attention, and the coal be fully converted into coke before entering the producer. The producer should be built and worked to obviate the formation of hard clinker, with mechanical grates for the continuous and clean removal of the ash. Automatic compensating devices would have to be included for the regulation of the pressure in the retorts during the run and blow periods. Such a plant, fitted with recuperators and waste heat boilers, would have a very efficient heat cycle, which would undoubtedly result in a large conservation of fuel. If the major portion of the coal used in this country were first treated by such a process, the fuel oil position would be made much easier, as greatly increased supplies would be forthcoming; the demand would accordingly greatly increase, and, as far as he can calculate, gas could be distributed to consumers at from one and a half times to twice the amount it would cost per heat unit to

supply as solid fuel. The saving in labour and transport, the cleanliness, and the efficiency of utilisation would far more than compensate for this increased charge.

COCONUT PRODUCTION IN TROPICAL AMERICA.

Coconuts have long been considered one of the most valuable products of the Tropics. The palm grows wild and is utilised in many ways by the natives of the tropical countries. The meat of the nut, eaten raw or cooked, forms an important article of food, and the liquid contained in the centre of the nut a most refreshing drink; the sap from the unopened flower buds is also used as a drink and is highly intoxicating if allowed to ferment for some time; the husk of the nut is used for fuel, and its fibres to make rope, matting, and brushes: the shell of the nut is used for fuel, for drinking cups, and various household utensils; the leaves and the wood of the palm are utilised for mats, thatching, and timber for huts.

Coconut products are exported in three forms, the whole nuts, the dried meat or copra, and coconut oil. Coconut oil is used in various products such as soap and candles, in addition to butter and lard substitutes. Copra is pressed to extract the oil, and the remaining product, either as copra cake or ground into copra meal, serves for cattle and chicken feed and for fertiliser. Fresh coconuts are converted into copra or the fresh meat is used in confectionery and pastry.

The bulk of these commercial coconut products comes from the Tropics of the Far East, notably from the Philippines, India, and Ceylon, the Malay Peninsula, and islands near it. The total quantity exported from tropical America is small compared with that exported from the Far East. With a few exceptions, little scientific cultivation has been attempted in the West Indies, Central America, or along the north coast of South America. There are but few large plantations; comparatively little copra is manufactured except that necessary to supply local needs; and the bulk of the exports consists of whole nuts which have been gathered by the natives in the wild groves fringing the coasts.

The British Government has encouraged coconut cultivation in its tropical colonies, including Trinidad, Tobago, and Jamaica, and several large American companies owning banana plantations in Central America and the West Indies are experimenting with coconut cultivation. Coconuts, scientifically grown on a large scale, are said to be one of the most profitable of tropical crops, but the large initial expenditure of capital necessary and the long wait for returns on this expenditure have prohibited any extensive development by native planters with limited capital.

From an interesting Memorandum on Coconuts in Tropical America, prepared by the Latin-American Division of the United States Bureau of Foreign and Domestic Commerce, it appears that Trinidad, Tobago and Jamaica are the only West Indian islands where coconut raising has become an important industry, although Hayti, Cuba and Porto Rico also export small quantities of coconuts and copra. Coconuts grow on some of the smaller islands, but are not exported. During 1917 the total exports of coconuts from Trinidad numbered 17,355,712, valued at about £93,000, of which 16,595,282 nuts were produced locally and 760,430 were produced outside the island, chiefly in Venezuela. Most of these nuts were shipped to the United States. During the same year the exports of copra amounted to 7,201,448 lb., valued at about £107,000, less than half of which was shipped to the United States. All the copra exported from Trinidad in 1917 was locally produced. The constant planting of new trees which is going on in the island ensures increased exports within a few years.

Trinidad has some 27,000 acres planted in coconuts with probably two-thirds of the trees now bearing.

Tobago, about one-fourth the size of Trinidad, has about 9,000 acres planted in coconuts but only a few of the trees are bearing. The two chief coconut districts of Trinidad are the Cedros district, which covers about 9,640 acres planted to coconuts, of which some 7,000 are now producing nuts, and the Mayaro district which includes about 7,500 acres of coconut trees all old enough to bear.

The Cedros district includes the plantations on the narrow peninsula situated at the extreme south-western part of the island, and also plantations stretching from this peninsula along the coast of the Gulf of Paria almost to La Brea near the famous asphalt lake. The present annual production of this district is now about 21,000,000 nuts, and probably will be doubled within the next eight or ten years. About 50 per cent. of the nuts produced are selects, 30 per cent. culls, and 20 per cent. rejects. The selects and culls are usually exported as whole nuts and the rejects manufactured into copra. Nearly four-fifths of the nuts are raised on large plantations owned by English companies or planters of French and English extraction. The cost of working these large estates is considerably less per acre than that of working the small holdings. The Mayaro district consists of a narrow strip of land on the southern part of the eastern coast of the island and is about 17 miles in length and ½ mile in width. About 12,000,000 nuts are produced annually in this district. The nuts are smaller than those raised in the Cedros district and about 80 per cent. of them are rejects.

In 1916 and again in 1917 Jamaica exported some 27,000,000 coconuts, the larger part of both crops going to the United States. These nuts were shipped in bags containing 100 or 150 nuts each, and the value of the entire amount exported in 1917 was approximately £145,000. About 35,000 acres are covered with coconut palms, and there is plenty of agricultural labour obtainable.

During 1917, Cuba exported 3,393,000 whole

coconuts to the United States and 5,432 kilos of copra. According to the Cuban Department of Agriculture, coconut palms are found scattered all over the island, but they are only grown for commercial purposes around Baracoa, which is situated on the northern shore of the island at the extreme eastern end. The average annual production of this district was estimated to be approximately 8,000,000 nuts during the three-year period ending in December, 1917. Coconuts are also found in the southern part of the Isle of Pines. Bud-rot disease, which became prevalent in 1904, has reduced the production of the Baracoa district nearly 50 per cent. and, as no effective remedy has yet been discovered, bids fair to reduce it still further. The spread of this disease, unfavourable soil conditions, and the little care accorded to commercial plantations have united to make coconut culture an unprofitable business in the island.

In Porto Rico the coconut industry has shown a steady increase. The exports amounted to £114,000 during the fiscal year 1918. In 1916 over 6,000 acres were covered with coconuts, and additional plantings were being made. Practically no copra is manufactured in Porto Rico, because of the large local demand for the ripe whole nuts. The Porto Rican nuts produce an exceptionally good quality of coir fibre, about 300 lb. of fibre being obtained from 1,000 nuts.

During the calendar year 1917 the Dominican Republic exported 422,330 kilos. of coconuts and 167,000 kilos. of copra. The Republic of Haiti only exported 60,456 kilos. of coconuts during the year ended the 30th September, 1917. Practically all nuts exported from the Dominican Republic are shipped from the port of Samana and are produced around Samana Bay. Although there are no large estates, the cultivation being done on a small scale, there are estimated to be approximately 9,000 acres planted to coconuts in this region. Bud-rot has done considerable damage to the coconut palms in the last few years. The nuts are usually shipped in jute sacks containing 100 nuts each. Coconuts grow all around the coast of Haiti, and at many points in the interior, but regular plantings are few in number and widely scattered. The nuts are said to be most abundant in the vicinity of Anglais Bay on the south side of the Tiburon Peninsula.

Panama exported to the United States in 1918 coconuts to the number of 19,758,949, valued at about £176,000. Of this quantity, some 6,000,000 were re-exports from the island of San Andres, a possession of Colombia, about 250 miles north-west of Colon. Practically all coconuts are exported from Panama in the shell, prices being quoted per 1,000 nuts. The nuts weigh about 1,650 lb. to 1,000 nuts.

The coconut crop of Panama ranks next to its banana crop, and is steadily increasing in importance as new areas begin to bear; banana plantations which have suffered from the blight are being converted into coconut plantations. The famous San Blas nuts of Panama are gathered by the San Blas Indians from territory which they control, a stretch of land about 120 miles long bordering the Atlantic, and some 365 small islands near the coast. This district alone has about 300,000 trees. These nuts and those grown on the Pacific coast of the Panama known as the "choco" nuts are among the finest in the world. The nuts are large, the meat is very sweet, rich, and white, and is easily removed from the shell. Coconut raising and gathering are also carried on by natives and Spaniards on the Palenque coast some 30 miles north-east of Colon, and, recently, coconut cultivation has been started on the Pacific coast by Americans.

During the year 1916-17, Honduras exported 10,533,572 whole coconuts (most of them through the port of Roatan), 149,772 lb. of copra, and 4,442 lb. of cohune nuts. Most of the whole nuts and all the copra and cohune nuts were shipped to the United States. According to the 1916 statistics of Honduras, there are 2,252 acres in the Republic covered with coconut palms in addition to the large groves on the Bay Islands just off the north coast. On a well-kept plantation the average annual yield is about 70 nuts per tree, and the nuts weigh about 150 lb. per 100 nuts. Two small copra factories have been established to utilise the rejects, one factory at Roatan on the Bay Islands, and the other at Puerto Cortez on the north coast.

Coconuts are not among the principal exports of Costa Rica. However, there are 750 acres of coconuts under cultivation on the eastern coast, and there are scattered groves on the western coast. Like the banana tree, the coconut palm here is attacked by insect pests, which may eventually destroy the tree entirely. One of the greatest pests is a large beetle called the chinoceros beetle, which gets into the crown of the tree and eats the fresh shoots until the tree loses its vitality and dies.

During 1917 Nicaragua exported 1,097,423 coconuts, most of which went to the United States. An American concern has purchased large plantations stretching for 35 miles along the coast between Greytown Harbour and Punta Roca. It has 61,000 new trees, and 30,000 good bearing trees. The monthly production of nuts is said to be about 35,000. The Corn Islands off the east coast of Nicaragua contain dense groves of coconut trees, from which it is reported 400,000 nuts could be exported monthly if sufficient shipping facilities were assured. Large ships do not visit the Corn Islands owing to lack of harbour facilities, and the nuts are shipped, therefore, in small schooners to Colon, whence they are re-exported.

Bananas have been found to be a more profitable crop in Guatemala than coconuts, and consequently the cultivation of the latter has decreased during recent years. In 1915, the last year for which official statistics are available, 8,175 bundles weighing 50 lb. each were exported from Puerto Barrios to the United States. The trees thrive in Guatemala and respond well to care and cultivation. In the few coconut plantations maintained, the average annual yield is 200 nuts per tree.

In 1914, the latest year for which figures are available, British Honduras exported 6,411,477 coconuts, of which over 6,000,000 were shipped to the United States. In addition, the colony sent 140 tons of cohune nuts to the United Kingdom and 92 bags to the United States. A small amount of sun-dried copra has been produced in Belize since 1915. Little information is available concerning the cultivation or gathering of coconuts in British Honduras. They grow wild for 50 miles up the Belize River Valley.

It will be noticed that cohune nuts appear among the exports from Honduras and British Honduras. These nuts are similar to coconuts but are smaller, and have a very hard shell. They are a native product of Central America and Mexico, and have been found to yield an edible oil much like coconut oil, and of equally good quality. They have not yet been exported to any great extent, but if prices were sufficiently high could be collected in considerable quantities.

In British Honduras alone there are estimated to be 2,000,000 acres covered with cohune trees; but until the war demand for charcoal made from coconut and cohune-nut shells, no effort had been made to export cohune nuts. The trees occur in dense groves on the so-called cohune ridges where the soil is fertile and the drainage good. Large numbers are also found on the "broken ridges" where the best stands of mahogany occur, but here they are dwarfed by the dense growth of other vegetation, and only an occasional tree which has a good supply of light and air bears fruit. About 25 miles inland in the Belize Valley they begin to replace the coconut trees, and about 75 miles up the river the coconuts disappear and cohunes become very abundant. The centre of the best cohune district is 75 to 100 miles from the sea. Farther inland than this the trees begin to decrease gradually, although they are found in large numbers in adjoining parts of Mexico and Guatemala. At other points in British Honduras, such as Stann Creek and the New River, the cohune is found much nearer the sea. From the cohune district as a whole, it is estimated that there is an annual production of 25 tons per 1,000 acres, or 50,000 tons per year. It is impossible to utilise more than a fourth for commercial purposes because of the inaccessibility of many of the groves, the lack of transportation facilities, the large overhead cost of gathering the nuts, and the shortage of labour.

In Honduras the nuts are found upon the low lands toward the eastern portion of the north coast. In the Aguan River Valley there is a single field 1 to 12 miles wide and 60 to 70 miles long. Persons familiar with the industry who have been over this field estimate that an equipped force of 500 men could collect 10,000 tons of nuts from this tract alone. There is no railway up this valley at the present time, but there are good prospects of one reaching the valley in the near future. The cohune nut in Honduras varies in size, measuring from 1 to 2 inches in diameter and from 1½ to 3 inches in length.

Cohune nuts are found growing wild everywhere in the swamp sections of the Nicaraguan coast. The quantity is not known, except that considerable areas of swamp contain them. It is estimated that the cost of gathering the nuts would be about £4 a ton.

Cohune nuts grow up to an altitude of 1,500 feet on the south shore of Guatemala and to an altitude of 500 feet on the north shore. It is estimated that on the south coast there is an annual production of at least 2,000 tons of nuts, which could be shipped over the International Railway to the ports of Ocos, Champerico, and San José. On the north coast the nuts occur in three separate sections—in the valleys of the Sarstoon, the Dulce, and the Motagua Rivers. The Sarsoon Valley is inaccessible, and hence it is impossible to get the nuts out; the valley of the Dulce contains what is perhaps the richest cohune tract in Guatemala. but as yet it is practically unexploited; the Motagua Valley is tapped by the International Railway and branch lines of the United Fruit Company. This last district was opened up to some extent during the war.

To turn to South American countries producing coconuts the chief would appear to be Brazil, Colombia, British Guiana, Venezuela, and Ecuador. In 1917 Brazil exported 2,243,000 coconuts, 15,680 kilos of copra, and 72,230 kilos of coconut oil. Scattered groves of coconut palms are found along the Brazilian coast from the northern boundary south to Bahia and up the valley of the Amazon as far as Manaos, but, of course, rubber gathering is the chief industry of the tropical jungles of the Amazon Valley.

At present the productive coconut belt of Brazil is included in the States of Parahyba, Pernambuco, Alagoas, Sergipe, and Bahia, and the exports are shipped mainly from Cabedello, Pernambuco, and Maceio. About three-fourths of the coconut trees of the district are centred around the ports of Cabedello and Maceio. The groves fringing the coast of this district vary in size from a few hundred trees to 40,000, the total number of bearing trees approximating 1,250,000, and the total production of nuts 50,000,000. The average size of these nuts compares well with the size of the products of other tropical countries, 5,000 nuts being required to produce a ton of copra. Even in the coconut belt very little copra is made, no seed selection is practised, trees are crowded close together, and the vitality of the trees is lowered by continued picking of the green nuts, of which large quantities are consumed in the country. Coconut raising might become very profitable if modern methods of cultivation were employed. Disease and pests are almost unknown, labour is cheap, and the local markets for the by-products are good.

During 1915, the last year for which official statistics are available, Colombia exported 74,075 kilos of coconuts, all to the United States.

No definite information is available concerning coconut cultivation or gathering in Colombia, but the American Consuls at Santa Marta and Barranquilla report that there are only a few scattered groves in their respective districts. Apparently exports from the small islands of San Andres and Providencia are not included in the official Colombian statistics. Coconuts form the chief source of wealth of these islands, which are said to export between 3,000,000 and 6,000,000 nuts annually. They are shipped in sailing vessels, either direct to the United States or to Colon for re-export.

In addition to the coconuts exported in 1915, a few kilos of corozo or cohune nuts were shipped from Barranquilla. These nuts are reported to grow in many parts of tropical Colombia in considerable quantities, but are not gathered at the present time.

British Guiana exported 1,911,404 coconuts in 1917 and 168,784 lb. of copra. These commodities were shipped to the United States, Canada, and England. British Guiana, not being subjected to severe hurricanes, is particularly suited to raising coconuts, and increased attention has been given to this industry in the last few years. Fully 17,000 acres of palms have been planted recently.

During 1917, 491,750 kilos of coconuts and 41,332 kilos of copra were shipped from Venezuelan ports and, in addition, many of the coconuts produced on the Venezuelan side of the Gulf of Paria were exported from Trinidad. Copra made in Venezuela is practically all sun-dried.

Coconuts are produced on various parts of the coast of Venezuela. The district around the Gulf of Paria is said to produce 2,500,000 nuts per year, of which 1,800,000 to 2,000,000 are raised on one large estate containing 60,000 trees. Just west of the Gulf of Paria, stretching from Carupano to Cumana but centering around the small Gulf of Cariaco, is another coconut district which is said to produce about 3,000,000 nuts annually. The towns of Guanta and Cumana in this district have a considerable oil and soap-making industry.

No recent Mexican statistics are available which give exports of coconuts, but United States import statistics show a very small amount of coconut products imported from Mexico during the fiscal year 1918. The wild coconut groves which fringe both the Atlantic and Pacific coasts of the country have been injured during the last few years by soldiers and bandits, and the disturbed condition of the country has prevented cultivation or gathering of the nuts for commercial purposes. Mexico affords a good field for coconut cultivation under normal conditions.

In addition to the wild coconut groves on the coasts there are groves of "coquitos" (little coconuts). These nuts are gathered in the winter season and used by the local soap factories, but are not exported.

THE SEAL OIL INDUSTRY.*

The sealing industry is actively pursued in the North Atlantic, in Alaskan and Siberian waters, and in the Caspian. Seals are valued for their furs, skins, and oil. The oil is chiefly obtainable from the hair seals. These are of numerous species. According to Dr. Charles H. Townsend, a leading American authority on seals, the most important from the oil standpoint is the Newfoundland harp seal (*Phoca groenlandica*), which has a very wide distribution, and is probably the most abundant of any species of seal. A small number of hooded seals (*Cystophora cristata*) is included in the annual catch. It is taken upon the Arctic ice from Newfoundland to Baffin Bay, and from Greenland across to the perpetual ice fields north of Europe. The seals are taken in their breeding places on the drifting ice, where the crews land and kill the younger animals by clubbing. More than ninety per cent. of the catch is made up of young seals, taken before they are three weeks old, when they are large enough to enter the water. Owing to the fact that this species is taken upon the ice fields, and that the latter are at times greatly disturbed by storms, the catch of seals is subjected to certain natural limitations. After the more effective steamers had replaced sailing vessels it became necessary to place restrictions upon the slaughter of the animals. At the present time the season begins on March 16, and the period during which seals are taken upon the ice lasts little longer than a month.

Caspian Seal.

Although seal fisheries are naturally associated with the great oceans, an important sealing industry is that of the Caspian Sea, which has long been carried on in this inland brackish lake. The seal which is the basis of this fishery (*Phoca caspica*) is a species peculiar to the locality, which probably found its way to its present habitat in very ancient times, when the Caspian was connected with other seas. About thirty years ago the average annual seal catch in the Caspian Sea was slightly over 100,000, worth in skins and oil $350,000. There are no recent data at hand.

Lake Baikal Seal.

Another seal (*Phoca sibirica*), remarkable chiefly for its habitat, is that found in Lake Baikal in the heart of Siberia. Here, however, the range of seals is restricted to a body of water only 400 miles long, and their numbers are too small to be of more than local importance.

West Indian Seal.

The West-Indian seal (*Monachus tropicalis*) was formerly abundant in the Caribean Sea and the Gulf of Mexico, extending north-eastward to the Florida keys and the Bahama Islands. This species, valuable for its oil, was practically exterminated over one hundred years ago. A few individuals of

* Extracted from an article by Bertrand A. Goodwin, in *The Street*, New York.

the race still linger on the Triangle Islands in the Gulf of Campeachy, where occasional specimens are procured for museum purposes. A seal of this species lived five and a half years in the New York Aquarium.

ANTARCTIC SEALS.

The various species of Antarctic fur seals (*Genus Arctocephalus*) were found about the southern shores and islands of South Africa, Australia, New Zealand, and the islands of the Antarctic generally. About the close of the eighteenth century a traffic sprang up in the skins of fur seals, and as the result of the many voyages made to those distant regions enormous numbers of fur seals were taken. They exist to-day as mere remnants of the great herds that were once found in those parts. By 1830 the supply of fur seals in the southern seas was nearly exhausted. In this sealing no discrimination was made in the character of the seals taken; all animals whose skins were of any value were slaughtered, and the newly-born young, usually left on the killing grounds, died in consequence. In the rush for seals to the Antarctic sealing grounds the markets were frequently glutted, and much of the catch wasted.

There are few parts of the world where seals of some species do not occur. All seals breed on land or on ice floes, and return, after their migration, to their accustomed breeding places with great persistence. They can seldom be driven entirely away, stupidly lingering until brought near to the point of extermination. So certain are the seals of returning to their breeding grounds, that the re-establishment of the different species soon follows the protection of these places. The safe-guarding of depleted sealing grounds would, in fact, be a good business proposition, even at this late day, if they could be protected under the authority of the various governments laying claim to such lands.

SOUTH AFRICAN SEAL.

The South African fur seal (*Arctocephalus delalandi*), frequenting small islands off the west coasts of South Africa, became very rare from indiscriminate sealing. It has, during very recent years, been protected by the Government of Cape Colony.

GALAPAGOS SEAL.

One resort of the genus *Arctocephalus*, the Galapagos Islands, lying on the equator, about 800 miles west of Ecuador, furnishes a striking illustration of wasteful sealing: Fur seals (*Archocephalus philippi*) were taken from the Galapagos Islands in important numbers by early voyagers. Between 1870 and 1882 these rookeries were again visited by sealers, and as far as appears from the meagre records collected from the sealers still living, who engaged in this fishery, about 20,000 seals were taken. This is, of course, a trivial number as compared with the total catch made during that period, the records of which are not available. The later voyages to the Galapagos Islands resulted in the killing of all the seals that could be found.

GUADELOUPE SEAL.

Another species of fur seal (*Arctocephalus townsendi*), the most northerly off-shoot of the Antarctic race of fur seals, formerly inhabited Guadeloupe and other islands off the west coast of Lower California. From the scattered records that have been found, it appears that 15,000 seals have been taken there within comparatively recent years—the earlier records are not available. During the writer's visit to Guadeloupe Island, in 1892, straggling fur seals were observed about the island, and specimens obtained which proved the species to be new to science. It is possible that there is a sufficient remnant to warrant the belief that the race could be re-established if the islands were properly protected by the Government of Mexico. The value of fur seal-skins taken in tropical or semi-tropical localities is small as compared with those from cold climates.

LOBOS SEAL.

In all the history of Antarctic sealing there is but one chapter of wise management and thought for the future; the Government of Uruguay has throughout all these years, carefully preserved the fur seal rookeries of Lobos Island, at the mouth of the La-Plata River, inhabited by *Arctocephalus australis*. These small rookeries illustrate the good resulting from the careful protection of fur seals upon their breeding grounds. Commercial sealing was carried on at Lobos Island prior to 1820. The lessees of the island, operating under the direction of the Government of Uruguay, placed upon the London market, from 1873 to 1904, 377,033 skins, or an average of over 13,000 a year, worth, in 1901, $100,000. All these were derived from a single island less than one mile in length.

OKHOTSK SEAL.

The history of Robbin Island, in the Okhotsk Sea, is especially interesting. This island is about 600 yards in length, and less than 100 yards in width, and yet incomplete records show that more than 60,000 seals have been taken there by raiders since 1870. A remnant of this herd has remained to repopulate the rookery annually, which at the present time contains little more than 1,000 seals, and is protected by the Russian Government.

The scattered fur-seal rookeries in the chain of volcanic islands stretching northward from Japan, known as the Kurils, have been destroyed by raiders during recent years. The history of the extermination of these seals, as furnished to the writer by men who engaged in the slaughter, is exceedingly interesting. Notwithstanding the fact that raids were made year after year, the scattered remnants of the herd still cling to their old breeding grounds. The incomplete records at hand show that more than 25,000 seals were taken from the Kuril Islands by raiders since 1880. These rookeries were visited by the U.S.S. Albatross in 1897, and all the rookeries were found to have been wiped out with the exception of one, upon which there were about 100 seals remaining. It is

believed that these will be protected by Japan, to which country they belong. The seal inhabiting Robbin Island and the Kuril Archipelago is now known as *Callorhinus curilensis.*

THE NEWFOUNDLAND SEAL FISHERIES.

The Newfoundland seal fisheries are to-day the most important from an economic standpoint. The seals are hunted in the ice by well-equipped sealing steamers along the north coast, in the straits of Belle Isle and Canso. This year's sealing season closed in April. Nine vessels, with crews of 1,586 men, were engaged, and the catch amounted to only 33,985 pelts, weighing 773 tons 14 cwt., valued at $159,929, as against 81,293 pelts, weighing 1,886 tons 12 cwt., valued at $278,145 for 1919, which was also a small catch as compared with those of previous years.

It is stated that the expenditure for fitting out the fleet this year was about $300,000, or nearly twice as much as it cost to fit out 22 steamers in 1900. When it is considered that only nine vessels undertook the voyage, it will be observed what strides prices have taken, particularly as to fuel and food. The loss to the Dominion resulting from the small catch is placed at $800,000. The returns of the Newfoundland sealing industry for the last ten years were:—

Year.	Number of Steamers.	Number of Seals.	Net Value of Catch. Dollars.
1911	18	304,591	494,075
1912	23	175,130	329,264
1913	19	272,965	493,845
1914	20	233,719	497,979
1915	13	47,004	93,479
1916	11	241,302	642,463
1917	12	196,228	516,756
1918	13	151,431	863,552
1919	10	81,293	278,145
1920	9	33,985	159,925

The Newfoundland seal fishery has been steadily prosecuted since 1763. In 1787 the average yield was about 5,000 seals. In 1871, 201 sailing vessels and thirteen steamers, employing 9,791 men, were engaged in the fishery. Between 1838 and 1848 the catch varied between 450,000 and 700,000 seals annually. In recent years the average has been 500,000 and 600,000 seals per annum. Only the young seals are taken. They are clubbed on the ice after they have come through the blow holes. The sealers collect the animals at intervals and deftly skin them.

THE GUTTA-PERCHA INDUSTRY.

Gutta-percha is a jungle product, obtained from trees growing wild in tropical forests. Borneo, particularly Sarawak, supplies the largest quantities, although Sumatra and the Federated Malay States furnish a certain amount. Some efforts have been made to cultivate the gutta-percha tree on estates, but they do not appear to have been successful, the reason being that the tree can only thrive in certain localities possessing the requisite humidity or rainfall and good drainage such as afforded by foothills, and these conditions occur very seldom outside certain jungle areas. So far as can be learned, writes the United States Consul-General at Singapore, there is only one district in Sarawak where gutta-percha trees have been cultivated with any success. This plantation has now been in existence about thirty years, and is only just beginning to yield supplies in marketable quantities. In this connection it may be stated that about twenty years are required before the trees are in a fair way to produce. If trees are tapped earlier, the production is small and a great risk is run of the trees withering and dying before becoming fully matured. This fact in itself would discourage the investment of any large capital in the industry, to say nothing of the extreme difficulty in successfully cultivating the trees outside their native jungles.

The milk of the gutta-percha is obtained by tapping, but in many cases the trees are cut down in order to obtain larger quantities. While this process does not actually destroy the life of the tree, inasmuch as new shoots will in time spring from the stump, it effectually cuts off the source of supply for many years. For this reason the felling of gutta-percha trees has, it is understood, been prohibited in Sarawak.

The latex is collected by natives, brought down to various villages, and bartered to the Chinese for rice, tapioca, salt, etc.

The production of gutta-percha in the various districts around Singapore is estimated to have been between 450 and 500 long tons in 1918, while in 1919 it was between 600 and 700 tons. The production is regulated according to existing values, and, should prices advance, it is anticipated that for 1920 it will amount to 800 or 900 tons. It is known that the production of gutta-percha is stimulated by further special inducements being made to the natives, who are the actual collectors. Without such inducements it is not probable that any appreciable increase in the present output of the commodity will be effected.

Another point to be carefully borne in mind with regard to the production and cost of gutta-percha is the constantly increasing area of land under rubber, coconut, and tapioca cultivation. These new estates are well regulated, and offer every inducement to the coolie type in the way of compensation and better standards of living. This class of work will, therefore, undoubtedly attract the native and coolie labour away from the jungle, and the clearing of so many tracts of land may mean the diminution of jungle areas and a consequent decrease in jungle products.

Gutta-percha to the amount of 1,469 long tons, valued at 1,468,792 dollars (U.S.), was imported into Singapore during the year 1918. Of this amount 1,372 tons, at a value of $1,358,764, were imported from the Dutch East Indies, while only 91 tons, valued at $107,431, were imported from British North Borneo, Sarawak, and the Federated Malay States.

Of gutta inferior, 5,243 tons, valued at $518,975, were imported into Singapore during the year 1918, most of which came from Dutch Borneo and Sarawak, Sumatra furnishing only 300 tons.

The following table shows the quantities, values, and countries of destination of gutta-percha and gutta inferior exported from Singapore during 1918:—

Countries of Destination.	Quantity.	Value.
GUTTA-PERCHA.	Tons.	U.S. Dollars.
United Kingdom . . .	1,596	1,556,357
Canada	138	44,895
France	113	43,909
Italy	30	11,447
Japan	33	22,755
United States	1,230	362,736
Total	3,140	2,042,099
GUTTA INFERIOR.		
United Kingdom . . .	99	9,539
Canada	71	6,365
Australia	17	1,797
Other British possessions	1	42
France	10	1,022
Japan	144	16,009
United States	834	89,959
Other foreign countries .	2	227
Total	1,178	124,960

SALT RESOURCES AND PRODUCTION OF POLAND.

Rock-salt is one of the important natural resources of the new State of Poland. The principal deposits are in Galicia, or what was formerly Austrian Poland, on the northern slopes of the Carpathian mountains, where the mines have been exploited since the twelfth century. There are also rather important deposits in the Province of Poznania (Posen), which was formerly German territory.

In the Galician district there are two Government mines, one at Wieliczka and the other at Bochnia, both of which are not far from the city of Krakow. In addition to these, there are nine other salt mines in the eastern part of Galicia. Wieliczka is known as one of the greatest salt mines in the world, embracing two square miles. Before the partition of Poland it belonged to the Polish Crown, but later it became the property of the Austrian Government and has now reverted to Poland. The estimated extent of the deposit is 21,000,000 tons of salt, and before the war its average annual production was about 110,300 metric tons, or about 60 per cent. of the total output of Galicia. One-fifth of the production was used for human consumption, and the remainder for cattle. The mine of Wieliczka is interesting as well as valuable, and the village exhibits to its visitors tables and chairs made of salt. The more important of the smaller mines are those at Bochnia, Kalusz, and Stebnick.

Although so large a proportion of the production of Wieliczka is used for cattle, the product obtained from the refineries of Eastern Galicia is almost entirely cooking salt. In 1895 the total output of the Galician salt mines was estimated at 129,500 tons, valued at about £710,000, whereas the annual production just before the outbreak of war was 141,200 metric tons, with a value of £760,000. The number of labourers engaged in the salt industry of Galicia was 3,500, and the Galician production amounted to 41·2 per cent. of the entire salt output of Austria. This exploitation was the monopoly of the Austrian Government, and owing to lax methods of production, the output fluctuated considerably. It is reported that the present condition of the Galician salt mines leaves much to be desired from a technical point of view, as a considerable part of the machinery is antiquated and of little use.

In the Province of Poznania the salt deposits have been exploited since 1870, the principal one being at Inowroclaw (Hohensalza), where the output amounted in 1906 to 55,713 tons of rock-salt and 25,556 tons of refined salt. Since that time, however, the production has decreased to some extent.

In what was formerly Russian Poland, there are salt refineries at Ciechocinek. These, however, are not of very great importance; they produced during the years immediately preceding the war some 3,000 tons annually. Formerly, this particular part of Poland imported a considerable amount of salt from Russia, but now that the rich salt deposits of Galicia are within Polish boundaries, the entire country will probably be supplied from this source.

The production of salt in Polish territories just prior to the war was thus approximately as follows: Former Austrian Poland (Galicia), 141,215 metric tons; former German Poland (Poznania), 81,269 tons; former Russian Poland, 3,007 tons; total, 225,491 tons.

There is no doubt, writes the United States Consul at Warsaw, that these Polish salt deposits are capable of much more intense exploitation and, under proper organisation, they could probably become the base for several branches of chemical industry.

Galicia also possesses at Kalusz the only potassium salt mines besides those at Stassfurt (Germany), and a company has recently been formed to exploit this deposit. These Kalusz salts are composed chiefly of kainite and sylvite. The production of kainite, which amounted in 1893 to 4,000 tons, had risen in 1913 to about 17,500 tons, valued at some £9,000. This deposit also was worked before the war by the Austrian Government, and it is hoped that now, under private initiative, it will become a considerably greater source of revenue.

OBITUARY.

Sir Arthur Charles Trevor, K.C.S.I.—Sir Arthur Trevor died suddenly of heart failure in London on October 22nd in his eightieth year. One of the sons of Captain R. S. Trevor, a victim of the plot organised by Mahomed Akbar Khan, following the outbreak of November 2nd, 1841, in Kabul, and the assassination of Sir Alexander Burnes, he was born at Jellalabad eight months before the murder of his father, and with his mother and brothers was among those in captivity after the massacre of the Jagdalak Pass. Educated at Oxford, he passed the Indian Civil Service Examination in 1860, and was posted to the Presidency of Bombay, where he had a long and distinguished career. While Commissioner of Customs he was chosen as British Delegate for the Portuguese Treaty. In November, 1890, he became Commissioner in Sind, and two years later the then Governor of Bombay, Lord Harris, called him to the Executive Council of the Western Presidency. Subsequently he was a member of the Governor-General's Council under Lord Elgin and Lord Curzon. Sir Arthur Trevor retired in 1901. He was elected a Life Member of the Society in 1891.

NOTES ON BOOKS.

English Public Finance from the Revolution of 1688. By Harvey E. Fisk. New York: Bankers' Trust Company.

This book has been prepared by the Bankers' Trust Company of New York, in order to give its American clients a better understanding of British finance and economics. The earlier chapters tell the story of the period August 4, 1914, to the budget speech of the Chancellor of the Exchequer on April 19, 1920. The later chapters discuss the national revenue, expenditure, and debt before 1914, and English methods of financing from the time of William the Conqueror.

The figures relating to the finances of the war are of very great interest, and no doubt their vastness will be as surprising to many in this country as to our friends in America. Thus Mr. Fisk points out that for the six fiscal years from March 31st, 1914, to March 31st, 1920, the expenditure of the Government actually exceeded the total expenditure for two and a quarter centuries preceding 1914. The exact figures are: for the 226 years £10,944,000,000; for the six years, £11,268,000,000.

The people of Great Britain paid into the coffers of the Government in taxes and other revenue collections over 36 per cent. of this vast sum of more than eleven thousand million sterling. The other 64 per cent. was borrowed. The war borrowings of Great Britain at their maximum, December 31st, 1919, amounted at par value of securities issued to £7,368,000,000, £6,011,000,000 furnished by her own people, £1,027,000,000 borrowed in and from the United States, and £330,000,000 borrowed from other foreign nations and from the Dominions. On the other hand, Great Britain had then loaned to the Dominions £186,000,000, and to her Allies £1,666,000,000, so that the amount loaned abroad exceeded by £495,000,000 the amount borrowed abroad.

Thus we find that the forty-six million people of the British Isles raised entirely from their own resources a net amount of £9,911,000,000, over £215 for each one of their number.

"What England requires to-day," writes Mr. Fisk, "to insure her material well-being is a heavy output of goods and services which the world will take in exchange for the food which she must buy in order to maintain her population and for the raw materials of manufacture, most of which she must seek without her own borders."

We are sincerely grateful to the Bankers' Trust Company of New York for having had this work prepared. It must assist in giving Americans a better idea of the enormous financial burden which has been thrust upon the shoulders of Great Britain by the war, and anything that will conduce to sympathetic mutual understanding between the two great English-speaking races on either side of the Atlantic deserves the warmest possible welcome.

The Centenary Volume of Charles Griffin & Co., Ltd. With a Foreword by Lord Moulton, P.C., G.B.E., K.C.B., F.R.S. London: Charles Griffin & Co., Ltd.

The firm of Messrs. Charles Griffin & Co. is to be congratulated on having completed a hundred years of useful service. Founded in Glasgow in 1820 the house soon decided to specialise in the production of technological works and scientific treatises mainly associated with industrial problems. It is difficult to exaggerate the importance of possessing a literature of this description. As Lord Moulton remarks in his foreword, "a rapid and sustained advance in our technology can alone save us from ultimate national disaster. With our huge populations, and their growing demands for food and increasing supplies of the necessary raw materials for our industries, there is no prospect of our being able to bear the burdens of the future, unless by advances in technology we are able to produce better and more cheaply than our competitors." In pouring out a constant stream of technological works of the highest order, then, Messrs. Charles Griffin & Co. may be said to have deserved well of their country.

The centenary volume opens with a short historical sketch of the firm, and this is followed by nine chapters written by well-known authorities describing the work carried out by Messrs. Charles Griffin & Co. in various branches of technology. Professor T. Hudson Beare deals with their record in connection with engineering. They published four works by Macquorn Rankine, then Professor of Engineering in the University of Glasgow, viz., "Applied Mechanics," 1858; "The Steam Engine,"

1859; "Civil Engineering," 1862; "Machinery and Millwork," 1869. These manuals are classics, and, to quote Professor Hudson Beare, "it is hardly an exaggeration to say that nearly all the engineering text-books which have appeared in the last half-century have to a great extent been modelled upon the lines laid down by Rankine, and are based upon principles which he first enunciated."

These works were followed by a long series of first-class productions, such as Professor A. Jamieson's "Steam and Steam Engines," "Applied Mechanics," "Strength of Materials," "Theory of Structures," "Hydraulics," and "Theory of Machines"; Farnsworth's "Constructional Steel"; A. E. Seaton's "Manual of Marine Engineering"; Bryan Donkin's "Gas, Oil, and Air Engines"; Professor Smith's "Suction Gas Plants"; and Professor Supino's "Land and Marine Diesel Engines." In short, the firm have provided engineers with text-books of the highest excellence in every branch of the profession. And what they have done for engineering they have also done for other callings: naval architecture, metallurgy, mining, chemical technology, medicine, the textile industries and science generally all owe a similar debt to Messrs. Griffin. Their record is a long and admirable one, and we wish them continued success under the guidance of their present chairman and managing director, Mr. Francis J. Blight.

GENERAL NOTES.

Société des Ingénieurs Civils de France (British Section).—The first meeting of this Section will be held at 8.30 p.m. on Tuesday, November 8th, at the Royal Society of Arts, when a paper on "The Destruction of the Mining District of Northern France, and the Work of Reconstruction" will be read by M. Edouard Gruner, President of the Société des Ingénieurs Civils de France. Fellows of the Society are cordially invited to attend.

A Cattle Food from Seaweed.—The exigencies of war have caused a number of attempts, more or less successful, to utilise Denmark's natural sources, and among the inventions reported is a process for producing a cattle food from seaweed. Several methods have already been proposed for producing such a food (more especially from sea wrack, *facus vericulosus*). This plant is abundant all over the world, but it has until now been impossible to transform it to a digestible state, and it also contains certain mineral substances which spoil the taste. The present process is described by the American Consul at Copenhagen as follows: The plant is thoroughly washed to get rid of the salt, then it is treated with steam, preferably under rather high pressure, which causes the cells to burst and allows the protoplasm to come out. This mass is placed under high pressure and formed into cakes, which are dried in a vacuum and ground into a coarse powder. The juice of the mass is boiled in a vacuum to a high grade of concentration which causes the salts to crystallize, and they are separated from the juice by means of a centrifugal separater. The juice is then mixed with the powder, and the mixture is pressed into pieces of suitable size. The analysis of the food is as follows: water, 5 per cent.; protein, 13·12 per cent.; fat, 1·07 per cent.; digestible carbonic hydrate, 66·76 per cent.; cellulose, 9 per cent.; mineral salts, 5·03 per cent. The analyses would seem to show this food to be nourishing, and the cattle are said to eat it willingly. It can be mixed with oil cakes.

Accidents in Mines.—According to the report of the Chief Inspector of Mines, the death-rate from accidents in and about mines under the Coal Mines Act for the year ending 31st December, 1919, was only 0·94 per thousand persons employed. This figure constitutes a record.

Sponge Industry in the Bahamas.—The gathering and the exporting of sponges are two separate branches of the sponge industry in the Bahamas, the gathering being still conducted in rather a primitive way. From a report of the United States Consul there, it appears that outfitters have a schooner or sloop locally built, at a cost of about £600 to £800, which is placed under the charge of a young captain, to whom a chance is offered for the buying of shares from his earnings in the vessel. One sponging boat is supplied by the owners with every schooner, while each member of the crew possesses his own boat also. The division of earnings at the end of a cruise of six weeks or two months is a complicated matter, the shares being allotted according to the man's position on board, private ownership of small boats, etc. All sponges obtained are sold on the Nassau Sponge Exchange by auction to buyers who ship the product to the United States and England. The total export of sponges in the year 1919 was 1,360,000 pounds, valued at 547,000 United States dollars, this amount including 337,000 pounds of sponge clippings valued at 4,000 dollars. Thus far scientific artificial propagation has not been pursued on any considerable scale.

Suggested Revival of Ancient Chinese Porcelain Industry.—An authority on Chinese porcelain is responsible for the statement, published by the United States Bureau of Foreign and Domestic Commerce, that it would be possible to produce such work to-day at the King Ta-chan potteries as in the days of Kang Hsi, although the cost would be practically prohibitive, and the colouring could not be duplicated, as the mineral colouring matter used is dug from mines in which the chemical components vary with the depth. It is said that the old moulds, patterns, and designs are still in existence, and that clay such as was used for the old ware is obtainable.

Journal of the Royal Society of Arts.

No. 3,546. VOL. LXVIII.

FRIDAY, NOVEMBER 5, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

CASES FOR JOURNALS.

At the request of several Fellows of the Society, cases have been made for keeping the current numbers of the *Journal*. They are in red buckram, and will hold the issues for a complete year. They may be obtained, post free, for 7*s.* 6*d.* each, on application to the Secretary.

CANTOR LECTURES.

The Cantor Lectures on "Recent Research in Cellulose Industry," by CHARLES FREDERICK CROSS, B.Sc., F.R.S., have been reprinted from the *Journal*, and the pamphlet (price 1*s.* 6*d.*) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ALUMINIUM AND ITS ALLOYS.

By W. ROSENHAIN, D.Sc., F.R.S.,

Lecture I.—Delivered April 12th, 1920.

PURE ALUMINIUM.

Particular interest has attached to aluminium ever since it was first produced on a commercial scale, mainly on account of its lightness. From the point of view of the present lectures also, we shall regard it mainly as a basis for the production of light alloys combining considerable strength with low specific gravity. From this point of view aluminium is practically the only metal available. At the present time the only practical alternative is the metal magnesium and its alloys, but these possess very considerable disadvantages, arising mainly from the fact that magnesium and its alloys are very easily corrodible. Another metal which may possibly come to be a serious rival to aluminium for the production of light materials of engineering is beryllium, otherwise known as glucinum. Of this, however, very little is yet known, and it is not yet available commercially.

Aluminium is of very widespread occurrence in nature. Many rocks and all ordinary clays contain a considerable proportion of aluminium. These materials, however, which are of the nature of impure silicate of aluminium, are not at the present time available for the production of the metal. The reason is that they do not readily lend themselves to economical treatment for the production of metal. The only sources of aluminium which are extensively used at the present time are the deposits of bauxite, which occur in various parts of the world. This mineral consists largely of oxide of aluminium (Al_2O_3), which is contaminated with varying proportions of iron and silica. One of the main difficulties in the metallurgy of aluminium, however, arises from the fact that the metal once produced cannot be readily refined. Consequently any impurities which are present in the ore in such a form that they become incorporated in the metal, cannot subsequently be removed economically. For the production of pure aluminium, therefore, it is necessary to utilise pure material, and this applies equally to the ore and to other materials which come into contact with the metal during manufacture.

The first step in the production of aluminium, therefore, consists in the purification of natural bauxite by chemical methods. This is an expensive and elaborate process. One method consists in the extraction of alumina from the bauxite by means of soda solution forming a solution of sodium aluminate. From this solution alumina (Al_2O_3) is deposited and soda is regenerated. More recently a process, for which

very great economy is claimed, has been put forward. In this a mixture of bauxite with carbon is heated in contact with an atmosphere of nitrogen to a temperature of from 1600° C. to 1800° C. As a result of this treatment, aluminium nitride is formed. Subsequent treatment of this nitride with soda yields ammonia and sodium aluminate. The ammonia thus produced is, of course, a valuable by-product, and it is said that alumina produced in this way costs little more than half that obtained by means of the older Bayer process.

Any steps which can be taken to secure a reduction in the price of aluminium are of vital importance to the industry of that metal and its alloys. The use of aluminium alloys as materials of engineering has become firmly established in certain directions during the war. If, however, it is hoped that their application may be extended to wider fields, it is essential that the cost of these materials should be very considerably reduced. Weight for weight, alloys are now obtainable which are far superior to steel, but on the other hand, steels—even the more expensive variety of alloy steels—are very much cheaper than aluminium or its alloys. Owing to the relative lightness of aluminium, however, this metal and its derivatives could successfully compete with steel even if the price of aluminium were still three times that of steel per ton. Even such a ratio, however, would require a diminution of the price to rather less than one-third of the lowest price level reached by aluminium before the war. It is obvious that such a development cannot be expected unless means are devised for utilising cheaper raw material and employing less expensive methods of treatment.

The final product of the purification of bauxite, which serves as the raw material for the production of aluminium metal, is pure, or nearly pure, alumina (Al_2O_3). The reduction of this oxide to the metallic state cannot be commercially carried out by the action of carbon alone. Electrolytic methods are therefore employed, and it is not possible to apply these to solution in water. The reason for both these difficulties lies in the very strong affinity which aluminium possesses for oxygen. Were it to be produced by electrolytic means in an aqueous solution, the metal would be instantly oxidised by action upon the water. The application of electrolytic processes has therefore to be carried out in fusion. Pure alumina, however, cannot be used for this purpose, because its melting point is far too high. The medium employed is therefore a solution of alumina in molten cryolite. Natural cryolite is a mineral found in Greenland, with a composition corresponding to the formula $Al_2F_6 . 6NaF$. A very satisfactory artificial product which serves as a substitute has, however, been produced, and this corresponds in composition to the formula $Al_2F_6 . 4NaF$. This material melts at a temperature near 1000° C., and is capable of holding a considerable amount of alumina in solution. The addition of 5 per cent. of alumina lowers the melting point to 915° C., and it is generally a fused mixture of this strength which is employed in the electrolytic reduction of aluminium.

The electrolytic reduction is carried out in a special and very simple form of electric furnace. In this appliance the current serves both to produce the electrolytic deposition of metallic aluminium, and to maintain the bath of molten cryolite at the proper temperature. The construction of the furnace is diagrammatically indicated in Fig. 1. A cavity for holding the molten bath is formed in a carbon block, A in

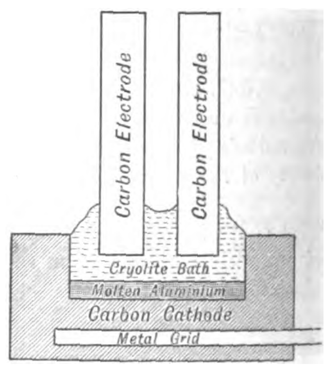

FIG. 1.

DIAGRAMMATIC VERTICAL SECTION THROUGH ELECTRIC REDUCTION FURNACE AS USED IN THE MANUFACTURE OF ALUMINIUM.

the Figure. In this carbon block is incorporated a metallic grid serving as electrode, to which one of the cables carrying the current is connected. The other pole is connected to the vertical carbon electrode, which hangs downwards into the molten bath. These furnaces work at a temperature of about 950° C., with a voltage between 6·5 and 7·5, a large number being connected together in series. The yield of aluminium is of the order of 1 kilogramme for 25 kilo-watt hours. The operation of these furnaces, however, involves certain special difficulties. In the first place, very great care must be taken in the manufacture of the

electrodes. Actually the amount of carbon consumed in the electrode is equal in weight, or nearly so, to the weight of aluminium produced. Any ash which is left after the consumption of the carbon of the electrodes necessarily enters the fused bath, and iron and silicon derived from the ash make their appearance as impurities in the metal. For the production of metal of a high degree of purity, therefore, it is very important that the carbon used for the electrodes should be very pure. Anthracite coal, which is usually regarded as a very pure variety of carbon, is not sufficiently good for this purpose, and it is necessary to employ coke obtained from the distillation of shale oils. For the production of very pure aluminium, it is further necessary for the workmen manipulating the furnace to exercise great care to avoid any risk of contaminating the metal by the use of iron tools, or by allowing any pieces of copper used in connecting up electrodes, etc., to fall into the bath. A further set of difficulties arises from the fact that there is only a very small difference of density between the molten aluminium, which is formed in the furnace and normally lies at the bottom of the bath, and the molten cryolite bath itself. Unless the working of the furnace is very carefully controlled, it may occur that through variations of temperature the density of the metal for a time becomes less than that of the bath. In that case the molten metal rises to the surface, and the output is spoilt.

When a sufficient quantity of molten aluminium has accumulated in the bottom of one of these furnaces, the bath is tapped and the molten metal is allowed to run out, first into ladles and is then poured into blocks. In this condition a certain amount of material derived from the molten bath itself is liable to be included mechanically in the aluminium. It is therefore necessary to subject the metal to a re-melting operation. After that process it is generally cast into the form of the well-known notched bars or ingots in which it comes upon the market.

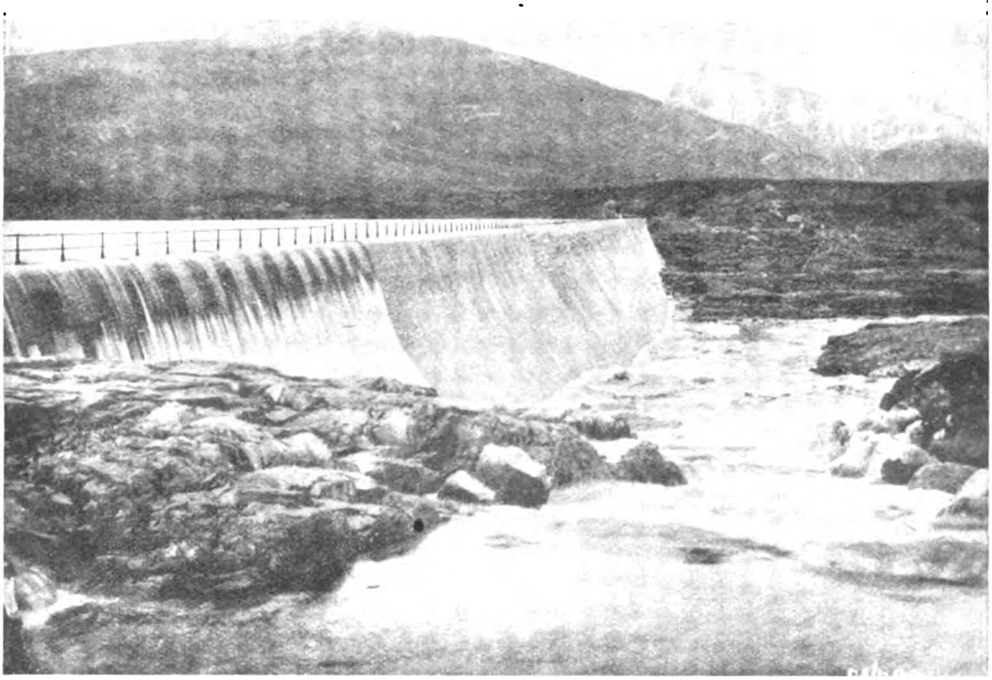

FIG. 2.

From the brief outline of the electrolytic manufacture of aluminium which has been given above, it will be seen that the economy of the whole process depends upon a cheap supply of electric power. It is therefore not surprising to find that aluminium manufacture has only proved practicable where cheap electric current could be obtained from water-power.

In Great Britain, aluminium manufacture is principally carried out in the works of the British Aluminium Co., at Kinloch Leven and at Foyers, both in Scotland, where water-power is available. By the kindness of the British Aluminium Co., photographs illustrating the works at Kinloch Leven are reproduced in Figs. 2, 3, 4 and 5. It has sometimes been suggested that the use of water-power for industrial purposes tends to spoil the natural beauty of mountain scenery. Indeed, a recent effort on the part of the British Aluminium Co. to extend their water-power considerably in the neighbourhood of Kinloch Leven was frustrated by the opposition of those who took the view indicated. Actually, however, it is found that the damming up of certain valleys, although it produces some changes in the scenery, does not by any means reduce its beauty; at any rate, it does so to a far smaller extent than would be the case by the erection of rows of smoking chimney stacks. Some of the photographs reproduced here may, perhaps, serve to show that the effect of the utilisation of water-power is not by any means so disastrous as is sometimes suggested.

FIG. 3.
WORKS OF THE BRITISH ALUMINIUM COMPANY AT KINLOCH LEVEN, SCOTLAND.

Having thus briefly outlined the manufacture of aluminium, we turn to consider its physical

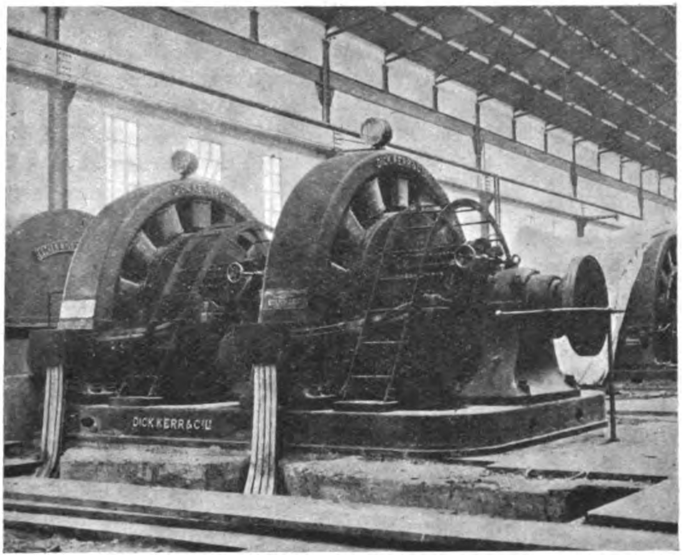

FIG. 4.

properties, which are remarkable and interesting. The first and most striking is the density, which is rather less than 2·6; this we may compare with the value for steel 7·8.

The thermal properties of aluminium are also remarkable and interesting. The thermal conductivity has a value of 0·51, as compared with 0·11 for iron. Combined with this high thermal conductivity, aluminium also possesses a very high specific heat (0·21), as well as a high electrical conductivity, which is about 60 per cent. of that of copper for equal volume, or 200 per cent. for equal weight.

The chemical properties of aluminium are also remarkable, and of very great importance. In the first place, it might almost be regarded as surprising that metallic aluminium can exist at all in an atmosphere containing oxygen and charged with moisture. We have already noted that the metal possesses a strong affinity for oxygen, and this property is utilised metallurgically. In the first place, there is the well-known thermite process in which iron and other oxides are reduced by the action of aluminium powder without the aid of external heat. Further, in the production of steel, and also in other metallurgical processes, aluminium is sometimes introduced as a cleansing and reducing agent at the end of the operation. Very large quantities of aluminium are used for this purpose in the steel industry.

In spite of this very strong affinity for oxygen, however, aluminium exists when exposed to ordinary air for a very long time without undergoing appreciable change. This apparent resistance to corrosion is due to the fact that the surface of the metal becomes coated with a transparent but protective film of oxide. The reality of the existence of this transparent surface film can be readily demonstrated, as has recently been done by Dr. Seligmann, by heating a sheet of thin aluminium foil. As a result of such heating the aluminium foil becomes largely oxidised. In spite of this

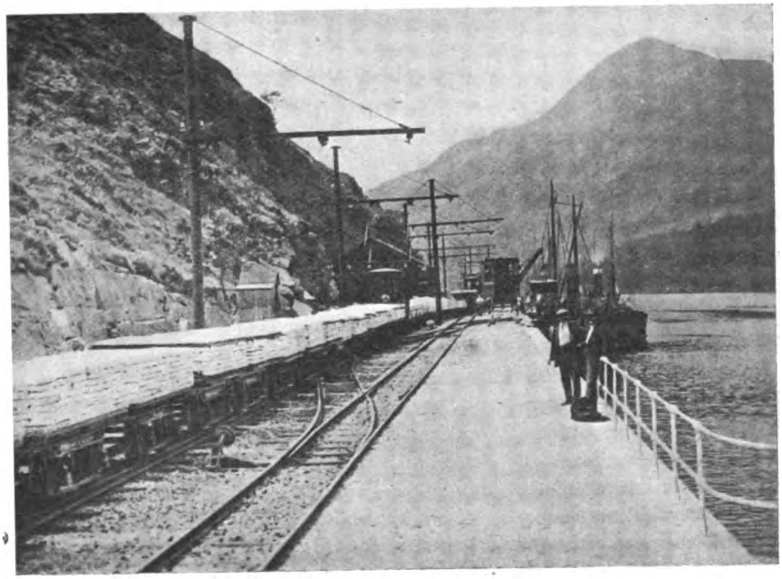

FIG. 5.

oxidation it retains its perfectly metallic appearance when viewed by reflected light. When, however, such a piece of oxidised foil is held up to the light, it is found to be very largely transparent. Similar evidence can be obtained from aluminium powder. Such powder can, by prolonged heating in a moist atmosphere, undergo very considerable oxidation, involving an increase of weight of more than 25 per cent. But the powder thus oxidised does not appreciably change in appearance.

The presence of a protective film on the surface of aluminium can also be demonstrated by the effects which arise when that film is removed. Where aluminium is exposed to the action of water, or even of a moist atmosphere, in such a way that the surface is constantly or frequently subjected to friction or abrasion, the frequent removal of the surface film leads to very rapid corrosion. The surface film can, however, be broken or removed in another way. If aluminium is exposed to the action of mercury under circumstances favourable to the combination of the mercury with the aluminium, that is, to the amalgamation of the aluminium surface, very striking results are produced. The presence of the mercury appears to destroy the protective action of the oxide film, and very rapid oxidation occurs. This can be shown very clearly by immersing a piece of aluminium sheet metal in a solution of mercuric-chloride for a very short time. After removing the metal from the solution and rinsing it with water and wiping it dry, a very rapid growth of alumina occurs on the surface of the metal. The alumina is formed in the shape of threads or fibres, which stand out from the surface of the metal like the fur of an animal. The process of oxidation is so rapid that the metal is perceptibly heated. (The lecturer demonstrated this phenomenon by painting the initials R.S.A. —Royal Society of Arts—on a piece of aluminium sheet with a brush charged with mercuric-chloride solution. The sheet was then rinsed and wiped, and in a few moments the initials began to appear in relief as the result of the rapid formation of oxide.)

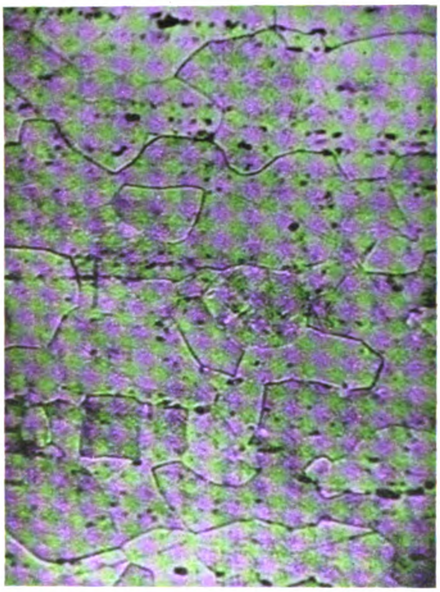

FIG. 6.

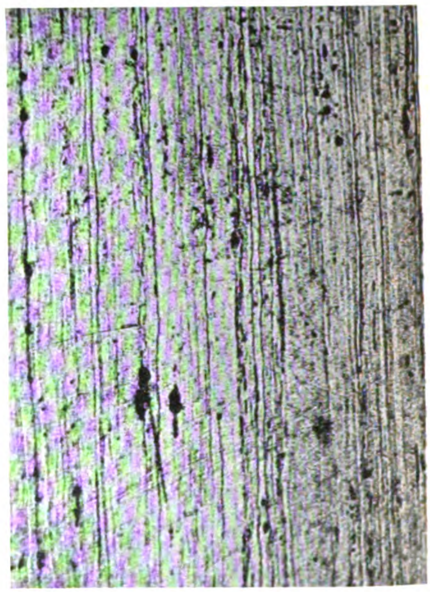

FIG. 7.

The protection of aluminium and its alloys from corrosion, is a matter of very great importance. In ordinary dry air, such as is met with in the interior of houses, railway carriages, etc., aluminium and many of its alloys preserve an untarnished surface for a very long time. No doubt it is this property which has given the metal the reputation which it appears to enjoy in some quarters of being particularly incorrodible. When, however, it is exposed to the action of water, and particularly of sea-water, very different results arise. Particularly if there is any friction, relatively rapid corrosion may set in, and this is liable to occur where the metal is exposed merely to spray and not actually immersed in the water. Protection can to a considerable extent be ensured by the use of protective organic coatings, such as varnish or bituminous paints.

Care must, however, be exercised in the choice of pigments employed for the coating of aluminium. It has been found that paints containing lead oxide are liable to be injurious, chemical action taking place between the aluminium and the oxide contained in the paint. Aluminium and its alloys can also be protected from corrosion to a considerable extent by electrolytic means. Aluminium placed in contact with steel, and exposed to water, is protected to a very large extent, but the corrosion of the steel is correspondingly accelerated. This is a result which is surprising at first sight, in view of the relative position of aluminium and iron in the electro-chemical scale. It is due, however, to the fact that the aluminium rapidly becomes coated with oxide, and thereby polarised electro-chemically.

The use of aluminium alloys of a particularly corrodible character as metallic protectors for aluminium, or its less corrodible alloys, has also been suggested recently.

Certain points of interest are presented by the micro-structure of aluminium. It should be mentioned in the first place, that the preparation of polished surfaces of pure aluminium is very difficult, owing to the great softness of the metal and the ease with which it is scratched, and with which it flows under the polishing operation. The structure of annealed aluminium is shown in Fig. 6 under a magnification of 150 diameters, while that of cold rolled material is shown in Fig. 7 under the same magnification. These photographs show the ordinary structure met with in approximately pure metal in the annealed and cold rolled condition respectively. Since, however, so-called pure aluminium is never entirely free from either iron or silicon, traces of these impurities are always to be found in the micro-structure. This is true even of the very purest varieties of aluminium ever produced, which probably attained a purity of 99.7 per cent. During the war, and at the present time, the standard of purity has been very much reduced, and so-called pure aluminium may not contain more than 98 per cent., and at best rarely contains more than 99 per cent. of aluminium. The appearance of iron and silicon in aluminium is illustrated in Fig. 8, under a magnification of 1,000 diameters. Silicon, when visible under the microscope, exists in the form of crystals of free silicon; iron, on the other hand, exists in the form of the compound $Fe\ Al_3$. These two bodies crystalise together in a peculiar manner, as indicated in the photograph, and a considerable amount of investigation has been necessary in order to make it possible to identify them definitely. With regard to silicon, it is interesting to notice that the whole of the silicon contained in the metal does not appear in the form of a separate micro-constituent. A certain amount may occur in the form of solid solution, and the amount found in this form will depend upon the thermal and mechanical treatment which the metal has undergone. When a chemical analysis is made of a sample of aluminium, it is found that the silicon appears in two forms; one part of the silicon becomes oxidised during the operations of dissolving the metal and appears as silica in the analysis. On the other hand, that portion which is present in the aluminium in the form of crystals of free silicon, remains

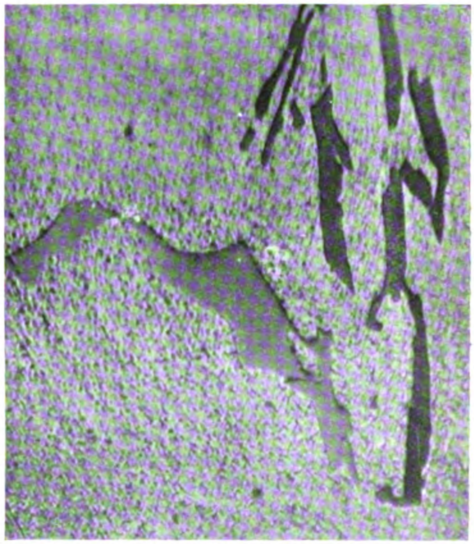

FIG. 8.

unaffected by the re-agents used, and appears as undissolved silicon in the residue. Microscopic evidence, however, completely explains this peculiar behaviour.

We turn now to consider the mechanical properties of pure aluminium, and it will be seen at once that from this point of view the metal is very disappointing. The tensile strength of commercially pure aluminium in the cast, rolled, annealed, and cold rolled states, is shown in Table I., p. 798, together with corresponding data for steel and brass.

It will be seen that the figures for aluminium are comparatively very low, and as a result the uses of aluminium for engineering purposes where strength is required are very limited indeed. It is actually valued mainly for its lightness, its very great ductility, and its colour,

TABLE I.—PURE ALUMINIUM.

Condition.	Yield Stress. Tons to sq. in.	Ultimate Stress. Tons to sq. in.	Extension. per cent. on 2 in.
Cast. 1 in. diameter.	2·3	5·22	37

Rolled *Mild Steel*	16·4	30·0	41
Rolled *Brass*	21·5	25·0	35

and power of resisting atmospheric corrosion. It is accordingly used wherever lightness is essential without great strength. It is used in the form of castings, rods, wires, and sheets, including among other uses, a considerable application as a conductor of electricity. It is also employed for panelling, and in the form of powder for paints, explosives, etc. One use with which many people are familiar is for cooking utensils. For more serious purposes of engineering, however, it is necessary to use alloys of aluminium which possess very much greater strength and hardness. It is, therefore, not surprising to find that the development of the engineering uses of aluminium has depended entirely upon the discovery of alloys capable of combining, as far as possible, the light weight and other advantageous properties of the metal itself, with a greater degree of strength and hardness.

BRITISH EMPIRE EXHIBITION, 1923.

As stated in the *Journal* of August 13th, it is proposed to hold in London in 1923 an exhibition representative of the industries and resources of the Empire. The objects, according to a White Paper, are "to foster Inter-Imperial interests from both a commercial and a political standpoint, and to demonstrate the natural resources of the territories of the Empire, and the inventive and manufacturing energy of its peoples. The exhibition will be privately organised, but is receiving official recognition and support. His Majesty the King has given it his patronage, and H.R.H. the Prince of Wales has consented to act as President of the General Committee."

In the House of Commons on Monday Mr. Kellaway (Secretary, Department of Overseas Trade) moved the second reading of a Bill authorising a Government guarantee up to £100,000 subject to private guarantees. Another stipulation is that the Board of Trade shall approve the manager of the exhibition, the executive committee, and the general conditions under which the exhibition is carried on. In the course of his speech Mr. Kellaway said:—

"The idea of the exhibition originated, I think, with Lord Strathcona. The idea was also supported by the Dominions Royal Commission appointed in 1912, and that Commission stated in its report that they found a general feeling not only in the United Kingdom, but also in the Dominions, that Inter-Imperial Exhibitions were likely to have an increasing tendency to promote Imperial trade, and that such exhibitions should afford a valuable opportunity to British manufacturers for developing their trade in the growing markets of the Dominions. The advent of the great war prevented that great idea from being carried through, and for five years it was in abeyance.

"At a Conference, held in 1919, at which were present representatives of this country and of all our great Dominions, it was decided that it was desirable that the proposal should be pushed ahead, not only with the objects which were originally behind the idea, but in order to provide a memorial of the great part played by the Empire during the war. The Empire in the war proved both its unity and its resources, and it is desirable, now that we are faced with the almost equally difficult and complex problems of peace, that the Empire should once more demonstrate its unity and its resources in dealing with these problems. Looking at it more particularly from the point of the interest of the United Kingdom, it has to be remembered—I think it is too often forgotten—that the United Kingdom itself is not a self-supporting unit; that it can only live by a great overseas trade."

The exhibition, he continued, was a form of Imperial Preference which raised no controversy. The possibilities for British trade within the Empire had not yet been sufficiently realised. It was regrettable that before the war the percentage of trade done with our oversea Empire showed a diminution, but there had been an improvement since the Armistice. In 1913 our exports to the Empire oversea amounted to £208,900,000, or 32·9 per cent. of the total bulk of our exports. In 1919 the figures were £215,300,000—and there was no comparison possible between the figures of 1913 because of the fall in the value of money—or 22·4 per cent. The figures for the first six months of this year were much more satisfactory, £236,700,000, or 30·6 per cent. That was a gratifying improvement, but we were dealing with an Empire population of, roughly, 450,000,000, and the possibilities of Empire trade were enormous. The exhibition would enable much more to be done in increasing that trade. The Committee of Management was very representative and strong, and the Guarantee Committee, which was going to secure the guarantee of £500,000 from private sources, contained some of the best-known men in the City.

Sir Frederick Banbury opposed the Bill on the ground that the time is not opportune for spending £100,000 on any project, however good. On the other hand, Mr. Clynes said that the proposal offered Parliament an opportunity to do a great amount of good to internal Empire trade. It was a step which would result in diminishing unemployment, and ought to have the support of every Labour member of the House.

After further discussion the second reading was agreed to by 205 against 30.

AIRSHIPS AND SEAL-FISHING.

In connection with the article on the Seal Oil Industry, which appeared in the last issue of the *Journal*, it is interesting to hear of a new development, particulars of which are contributed to the *Times* by a special aeronautical correspondent. The S.S. "Alconda" sailed from the Thames last week for Newfoundland, carrying four non-rigid airships, which are to be used early next spring in an attempt, by means of aerial observation and wireless telegraphy, to direct the course of the steamers setting out from St. John's in search of the seal herds which come drifting down on the ice from the far North.

The expedition, which has been organised and is being taken out by Mr. Frank J. Tippen, consulting airship engineer and constructor to the Newfoundland Government, and a well-known expert in this country on the design of large commercial airships, is a very complete one. Three of the four airships are of the "S.S." or sea-scouting type which, known familiarly as "Blimps," and driven by a single "Hawk" Rolls-Royce motor, did such valuable reconnaissance work in the war over the North and Irish Seas. The fourth is a larger ship of the same type, driven by a couple of Rolls-Royce motors. These four ships, with all necessary equipment and ample spares, have been presented to the Newfoundland Government by our Air Ministry as the nucleus of a regular Government air patrol service in Newfoundland, and after the experiment in seal-hunting they will be used as a matter of routine in survey work and forest patrol. The experience thus gained by the Newfoundland authorities will be of the utmost value and will, it is hoped, lead to the institution of other airship patrol services in different parts of the world.

Probably two of the airships will be employed in the first seal locating test, which will be made early next year. They will fly out over the North Atlantic, and keep in touch during their observations by means of the wireless apparatus they will carry with the fleet of sealing steamers, which puts out to sea each season from its base at St. John's with the intention of intercepting the vast herds of young seals congregated on the moving ice.

It is the young seals, with their oil-bearing fat and skins, which are so valuable. But the locating of the herds is always more or less a race against time. Immediately after the breeding season the seals come drifting down on the ice in their thousands, and their position must be located accurately and the catch made all within the period of a week or two.

Hitherto, in laying out a course likely to bring the steamers to the correct spot at the right time, the sealing fleet has relied mainly on the special knowledge and skill of certain skippers who study charts and drifts, and make the most of such information as comes to hand. But there is no certainty in such a method, and calculations go wrong sometimes, and the fleet to a large extent draws blank. Next spring, however, it is believed that the airship patrol, preceding the fleet and scouting over an immense area of water, should convert what has hitherto been a "gamble" into a practical certainty.

PETROLEUM IN MEXICO.*

A comparison of the figures of the production of oil in Mexico, in the United States, and in the world since 1912, shows that the Mexican production has multiplied more than three times in the last seven years. While in 1913 Mexico supplied only one-fifteenth of the world's production of oil, in 1918 it furnished more than one-eighth.

The statistics show that the world's actual production of oil in 1918 was about 515,000,000 barrels. The potential production of Mexico during 1919 was 547,000,000 barrels. By the term "potential production" is meant the amount of oil that would be produced if each well were permitted to flow without any restraint being placed on it. In 1919 Mexico was potentially able to produce 32,000,000 barrels more oil than was actually produced in all other countries in 1918, and 170,000,000 barrels more than the United States production of 377,000,000 barrels in 1919. The potential production of the wells already drilled and producing in Mexico is estimated at from 1,500,000 to 1,900,000 barrels daily. But only about 12 per cent. of the potential capacity of the wells in Mexico is being actually produced. The full development of the potential possibilities of the industry in Mexico has been hindered by the lack of transportation both for oil and materials, by the lack of sufficient storage facilities, and by the disorganised political conditions of the country. The application of new legislation to the industry, the effect of which it has not been possible fully to ascertain at this time, has tended to check development operations. Yet the exports of oil from Mexico in the first half of 1920 show a notable increase over the shipments in previous years, amounting to nearly 60,000,000 barrels, and representing an increase of 72 per cent. over the exports in 1919. If this rate of increase is maintained throughout the year, the total exports for 1920

* Extracted from Report on the Petroleum Industry of Mexico issued by the Bureau of Foreign and Domestic Commerce, Washington ("Commerce Reports," 13th September, 1920).

will reach 135,000,000 barrels in comparison with 78,000,000 barrels in 1919. The rising rate of exports is shown in the following table of the monthly shipments of Mexican oil in the first half of each of the last two years :—

Months.	1919. Barrels.	1920. Barrels.
January . . .	5,294,786	8,160,841
February . . .	4,911,984	7,687,943
March	5,179,076	10,560,535
April	6,132,903	10,155,279
May	6,329,722	12,052,568
June	6,917,641	11,220,720
Total, 6 months	34,766,112	59,837,886

The enormous output of the wells in Mexico can best be illustrated by a comparison with the wells in the United States. The oldest wells in America are in the Appalachian region, and number about 100,000, with an average daily yield of less than two-thirds barrel per well; the newest region is the Rocky Mountain with 400 wells and an average per well of 40 barrels daily; the mid-Continent field of America with nearly 50,000 wells averages 9 barrels daily; the California field with an annual production of about 100,000,000 barrels, yields an average of 30 barrels daily per well. If all the producing wells of Mexico are taken into consideration, we find that during 1919 the average actual production per well was approximately 1,000 barrels daily. There are twenty-five wells in Mexico, which, if permitted to flow without restraint, would yield 600,000 barrels daily, or an average of 24,000 barrels per well per day. During the first six months of 1919, eight producing wells were drilled in the Tampico region with a possible daily flow of 584,798 barrels.

Increasing attention is now being given to the exploration of various parts of the Republic for the discovery of oil. Geological conditions indicate that petroleum fields of greater importance than those now known will yet be discovered in Mexico. A late report places the zone of possible production in the Gulf Coast States at over 80,000,000 acres, on the Pacific at about 50,000,000 acres, and in Lower California at about 18,000,000 acres, a total of 148,000,000 acres, or 230,000 square miles. Of this immense area only about 6,500,000 acres have been investigated, which illustrates the scope offered for wildcat operations in Mexico. The combined area of the fields now being exploited in Mexico does not exceed 800 square miles. The discovery of what is believed to be extensive petroleum deposits on some islands in the Gulf of California has been officially announced by the Mexican Government. These islands are close to the shore of Sinaloa, due west of Hermosilla, and the deposit is said to extend to the mainland on the peninsula of Lower California. The southern district of this peninsula has given indications of an extensive petroleum zone, and it is being thoroughly explored.

Explorations are also being carried on in different parts of Mexico. Reports from geologists indicate that any discoveries made as a result of these explorations will probably be of a petroleum with a paraffin base, or with a smaller amount of asphalt than that now being produced.

The potential production of oil has been very seriously diminished by the invasion of salt water in several of the most important fields, including the Tepetate, Huasteca, and Casiano. The Potrero del Llano well, the property of the Mexican Eagle Company, after flowing for eight years and having produced more than 100,000,000 barrels of oil, began to yield salt water, and since December, 1918, it has been considered a loss. In November, 1919, the Casiano No. 7, actually producing 25,000 barrels daily, and owned by the Huasteca Petroleum Company, turned to salt water. The loss of this well caused this company to drop from first to second place in the production of Mexico in 1919. The wells of the Cortez Oil Corporation in Tepetate have been reported as having become a total loss through salt water. Seven of the principal wells of the Chinampa field have either ceased to flow or are yielding only water. From the Mexican Government's figures of a potential production of 1,592,740 barrels daily in March, 1919, and of 1,995,223 barrels daily in November, 1919, it would appear that the menace from salt water had not reached any great proportions, but it must be noted that during this time of apparent increasing potential production, the various companies had developed and brought in several new wells which more than offset the losses from salt water. The appearance of salt water in several of the oldest and largest producing fields will probably stimulate the exploration and development of other fields, particularly the known fields farther south.

Of the total investments in the oil industry of Mexico, 97 per cent. is held by foreigners. In the petroleum industry of the United States but 4 per cent. of the total amount invested is held by foreign capital. In 1918 there were twenty-seven companies in Mexico which produced oil in commercial quantities, seventeen of these being owned by Americans, five by Spanish-Mexican capital, three by Dutch, and two by British interests. Of the total of 63,828,326 barrels produced in Mexico in 1918, the American interests produced 73 per cent., British 21 per cent., Holland 4 per cent., and Spanish-Mexican 2 per cent. In 1919, however, the British interests materially increased their production. Only American and British interests shipped oil from Mexico during 1918, the oil exports having been 79 per cent. American and 21 per cent. British.

Production of oil in Mexico depends primarily, at this time, on transportation facilities. Mexico can ship oil only up to the maximum amount of ship tonnage available, and it is equally true that it is impossible to utilise this tonnage to the utmost if there are no pipe lines to move the oil to the ports. Certain conditions, both economic and political have brought about in some Mexican fields a surplus of pipe-line facilities, while in others, particularly the newer fields, production is delayed while lines are being constructed. It

has been estimated that the monthly shipments of 6,000,000 barrels of petroleum could be increased to nearly 17,000,000 barrels if adequate transportation were available. New pipe lines now under actual construction will increase the carrying capacity by about 200,000 barrels per day, and lines have been projected with a carrying capacity of 100,000 barrels daily. Not all the pipe lines are provided with pumping stations, these being unnecessary in many cases, owing to conduction by gravity. A great amount of the oil obtained in the Elbano, Panuco, and Topila fields is of such a low gravity and high viscosity that it cannot be economically pumped through pipe lines. The transportation of the Elbano oil is accomplished after removing the asphalt and heavy constituents and shipping the fuel oil in tank cars. A considerable amount of the oil from this district is used for fuel by the Mexican railroads. The Panuco product is exported from Mexico and has to be barged down the Panuco River to Tampico, where it is either loaded directly on the ships or stored. The oil from this district has such a high viscosity that it must be heated before delivering to barges or before loading on tank ships from storage.

Of the total exports in June, 1920, the shipments from the Tampico district amounted to 10,566,181 barrels. From Puerto Lobos the shipments were 3,384,513 barrels, and from Tuxpam 1,472,553 barrels. The United States took 71 per cent. of the total, South America 8 per cent., Great Britain 4 per cent., Cuba 3 per cent., and Mexico itself 4 per cent., the small remainder going to various countries of North America and Europe. In accordance with its usual record the Huasteca Petroleum Company was the largest shipper, its exports for the month of June totalling 2,189,750 barrels. Production was somewhat curtailed in June by floods in the lower country, which damaged the oilfields.

It is of interest to compare the above figures of Mexico's exports with the United States statistics of imports of Mexican oil. The total imports of oil from Mexico into the United States in the fiscal year ended 30th June, 1920, reached the record figure of 2,821,693,174 gallons, or 67,183,170 barrels (at 42 gallons to the barrel). This shows a gain of 991,598,069 gallons, or 23,609,478 barrels, over the imports of the 1919 fiscal year, which amounted to 1,930,095,105 gallons, or 45,954,645 barrels. The gain was 100 per cent. over the imports of 1918, when the imports were somewhat more than 1,000,000,000 gallons. The June, 1920, imports of Mexican oil were 340,197,600 gallons, or slightly more than 8,000,000 barrels.

The Carranza Government of Mexico was overthrown in May, 1920, by what amounted practically to a peaceful revolution. Adolfo de la Huerta, former governor of Sonora, has been chosen President *ad interim* by Congress pending the holding of a congressional and presidential election in the autumn of 1920. The public utterances of the principal persons in the new Government, as reported in the press, indicate a desire on their part to deal fairly with the foreign corporations engaged in the exploitation of Mexico's resources.

On July 2nd, 1920, the *Universal* of Mexico published the statement, which was claimed to be official, that the petroleum industry in Mexico was worth 600,000,000 pesos (300,000,000 dollars). This statement has been verified by a well-known engineering and geological expert. In detail the investments in the petroleum industry follow:—

	Dollars.
1,000 (approximately) wells perforated and producing	100,000,000
Value of the land upon which the wells are located	50,000,000
Pipe lines, railroads, and rolling stock	50,000,000
Refineries machinery, and buildings	50,000,000
Miscellaneous producing properties, of which the greater part belongs to Great Britain	50,000,000
	300,000,000

To the above might be added approximately 50,000,000 dols. as being invested in ships for the transportation of oil. American capital represents about 70 per cent. of the total investments in the petroleum industry in Mexico, and British and Dutch capital about 27 per cent., the remaining 3 per cent. being Mexican and other interests.

JAPAN'S FOREIGN TRADE.

The foreign trade of Japan for the first half of this year totalled 2,756,134,000 yen, comprising exports to the value of 1,138,838,000 yen, and imports to the value of 1,617,296,000 yen. There was thus, as the Commercial Secretary of the British Embassy in Tokio points out, an unfavourable balance of 478,458,000 yen, or more than double the adverse balance for the similar period of last year. Compared with the first half of 1919, exports show an increase in value of about 35 per cent., and imports an increase in value of about 55 per cent.

The exports which showed increases in value were raw silk, silk textiles, cotton textiles, refined sugar, waste silk, cotton yarn, braids for making hats, pottery, coal, timber, toys, tea, buttons, hats, and cement. Generally, however, there was hardly any increase in the quantities shipped; but braids for making hats, and matches, were noteworthy exceptions.

The exports which exhibited decreases were copper (ingots and slabs), iron (bars, rods, and plates), zinc (ingots and slabs), beans and peas, starch, woollen textiles, leather goods, and beer. The most notable decrease was in the case of copper. Japan is generally a copper-exporting country, but owing to the increased cost of output the local product has ruled considerably higher than the imported metal. There was naturally no outlet for Japanese copper, and the large merchants were obliged to import heavily in order to fulfil their commitments.

The imports showing increases included raw cotton, wool, oil cake, hides, pulp, woollen textiles,

flax and hemp, cotton textiles, caustic soda, soda ash, leather, toys, rubber, petroleum, nitre, sugar, beans and peas, machinery, rails, coal, lead (ingots and slabs), iron (bars, rods, plates, ingots, slabs, pipes and tubes, nails). The most noteworthy increase was that of raw cotton. This was in response to the expansion in the local textile industry, but owing to the slump a large proportion of it has been regarded as surplus stock, and holders were subsequently reported to be trying to re-export.

The imports which decreased were rice, copra, paper, and ores.

The continued excess of imports is, to a considerable extent, the result of the steady import of raw cotton from America during the first part of this year, which had been held up owing to various causes, such as strikes of stevedores and shortage of space. The sudden change in all economic conditions which occurred during the period under review, brought about a general suspension or curtailment of textile manufacture to begin with, and also of the production of silk, cotton yarn, hosiery, etc., and the difficulty in securing accommodation from the banks, combined with the unusual fluctuation of prices in the local markets, acted as a strong deterrent on export trade.

The Commercial Secretary adds that a great number of orders have been cancelled, and there will be strong retrenchment in such commodities as raw cotton and other raw materials, fertilisers, and, probably, machinery. It is also expected that there will be a decrease in the export of most of the articles which showed a heavy increase during the first half of the year, such as silk textiles, cotton textiles, waste silk, and sugar. However unsatisfactory the sale of raw silk may be, it is hoped that the figures for the latter half of the year will show an increase as compared with the first half-year. This hope may be justified so far as quantity is concerned, and the same may be stated about cotton textiles, silk textiles, and cotton yarn; but prices have gone down enormously. For instance, raw silk, which rose to 4,300 yen per bale during the latter part of last year, and to over 3,000 yen during the earlier part of this year, ruled at the close of the half-year at 1,400 yen to 1,500 yen per bale.

TOBACCO TRADE AND INDUSTRY OF HONG KONG.

The full scope and volume of the tobacco industry and trade of Hong Kong is not generally understood; in fact, it has not been fully appreciated in Hong Kong itself until recently. The publication of the trade statistics of the colony for the first six months of 1919 gives definite figures of the value of the trade for the first time, and is illuminating. The statistics point to a total value of the exports of prepared and other tobacco from the colony for 1919 of well over £2,000,000 sterling. The imports will probably reach a value of over £900,000, exclusive of those from South China, which amount to about £500,000 more; and the difference between imports and exports in a general way measures the value of the tobacco-working industry of Hong Kong.

The statistics of imports and exports for the first six months of 1919 are, in pounds sterling, as follows:—

	First six months of 1919.	
	Imports.*	Exports.
	£	£
Cigars	28,620	79,780
Cigarettes	136,440	598,432
Snuff	20	233
Tobacco:—		
Prepared, foreign	4,559	3,770
Prepared, native	4,094	309,267
Raw	222,895	211,543
Stalk	—	2,065
Total	396,628	1,205,090

* Exclusive of imports from South China.

According to a report by the United States Consul-General at Hong Kong, there are three lines of tobacco manufacture in the colony. One is a large cigarette factory, started several years ago by Chinese capitalists from Canton, and is known as the Canton Nanyang Brothers Tobacco Co. (Ltd.). The second factor is a large cigar factory which was started several years before the war as a branch of a Manila factory, and is known as the Oriente Cigar Factory. Like the Manila concern, it was owned more or less completely by German interests; with the inception of the war it was taken over by the Hong Kong Government for liquidation. It has been operated as a going concern by the liquidators ever since, and is responsible for most of the difference between the imports and exports of cigars noted above. Very little of the product of this factory is used locally. The third principal factor is the industry of the native tobacco dealers, in which the raw leaf is imported and manufactured mostly into fine-cut tobacco for use in native Chinese pipes, especially the small nickel and brass water-pipes.

Of the imports of cigars, the Philippine Islands furnish all but a small fraction; and of the imports of cigarettes about 20 per cent. came from Great Britain, about 7 per cent. from the Philippine Islands, and nearly the whole of the balance from North China, where the chief competitor of the local factory has its factories. Approximately 60 per cent. of the raw tobacco indicated in the official returns comes from the United States, the rest coming mostly from North China. But by far the larger part of the raw tobacco actually imported comes from South China. The value of the imports from South China (not included in above table) is about £600,000 per annum. The returns of the Chinese Maritime Customs give the

exports of tobacco leaf and stock to Hong Kong in 1918 as the equivalent of £182,000, and of prepared tobacco as the equivalent of £418,000. Most of this tobacco is of a cheap grade.

About two thirds of the cigars manufacted in Hong Kong, and of the cigars manufactured elsewhere and re-exported from Hong Kong, go to Central and North China, Siam and the Straits Settlements also being fair customers. About 40 per cent. of the exports of cigarettes go to China, 35 per cent. to the Straits Settlements, and most of the rest to the Dutch East Indies and other places where Chinese emigrants are numerous. Two-thirds of the prepared native leaf tobacco goes to the Straits Settlements, and most of the balance to Indo-China. Of the exports of native raw tobacco, the United States and Great Britain take about 20 per cent. each, Egypt about 25 per cent., and China most of the balance. During the war the export of this native leaf to Europe, and especially to the United States, became very large, for use in the manufacture of "Turkish" cigarettes.

It is of interest to note in this connection that experiments have been carried on for some time by the Botanical and Forestry Department of the Colonial Government in Hong Kong, with a view to producing in the colony itself tobacco leaf suitable for the manufacture of cigars. A considerable degree of success is to be noted, and experimental lots of cigars have been made. There is a considerable amount of terrain in the mainland portion of the colony considered suitable for the production of a high-grade leaf, and it is thought that under proper superintendence and instruction a large production of such tobacco can be developed.

CAMPHOR INDUSTRY IN FUKIEN.

A "boom" in the camphor-producing industry in the Foochow district commenced in 1904 and lasted about six years. In 1906, 1,516,600 lb., valued at about £193,000, were exported from Foochow; in 1917 the exports amounted to only 49,533 lb., valued at about £5,700.

At first a Japanese concern was granted a monopoly of the business; but this was cancelled on account of the protests of other foreign firms. An attempt of the Provincial Government to make a monopoly of the trade had injurious results. Trees were ruthlessly cut down and none planted to replace them, so that the reckless exploitation and lack of reafforestation soon killed the trade. The Government issued a regulation providing that five young trees should be planted for every one cut down, but nothing was done. Fukien camphor could not withstand the competition of Formosa camphor, which was produced by more up-to-date methods.

In 1918 there was a slight improvement due to the high prices offered, which made it profitable for certain dealers to expand their businesses. In that year exports from Foochow amounted to 56,533 lb., valued at about £11,000.

According to a report by the United States Consul at Foochow, camphor is now produced in the interior of that district to a limited degree by crude native ways of distillation. The product is brought by porters to the Min River or its branches and carried to Foochow by native boats.

The Government is anxious to revive the trade, and might be willing to bear at least a part of the expense of reafforestation. It is estimated that a capital of about £30,000 would be necessary to undertake the work on an adequate scale, but perhaps with modern distillation the trade could be made profitable, at least for a time. A foreign firm, unless backed by the Provincial Government, would meet endless difficulties in finding and recompensing the real owners of camphor trees. The trees do not grow in forests, but are scattered. When a tree is found near a grave it is necessary to purchase it from the owner of the grave as well as from the owner of the tree itself. There are no railways or good roads in North Fukien, and transportation is imperfect and expensive. Labour, however, is cheap.

CORRESPONDENCE.

CATTLE FOOD FROM SEAWEED.

In connection with the paragraph on the above subject in the *Journal* of October 29th, it is interesting to note that in Iceland, where there is very little pasturage, particularly in winter, the sheep near the coast go down to the beach and climb amongst the rocks to obtain seaweed, which they use as a food. It must be admitted that seaweed gives rather a peculiar taste to the flesh of the animals, and I am wondering whether it will be the same with the prepared cattle food which is now being made in Denmark.

When I was in Iceland in 1913 one farmer lost ten sheep by the rapid rising of the tide, and I understand that sheep are often lost in this way.

F. MOLLWO PERKIN.

OBITUARY.

LORD BELHAVEN AND STENTON.—Alexander Charles Hamilton, 10th Baron Belhaven and Stenton, died at his Scottish seat, Wishaw, on October 31st. A son of William John Hamilton, M.P., F.R.S., who was twice President of the Geological Society, and a grandson of William Richard Hamilton, antiquarian and diplomatist, who had so much to do with the collection of the famous Elgin Marbles, and recovered them after the vessel, in which they were being transported, was wrecked near one of the Ionian Islands, he was born in 1840, and entered the Royal Engineers in 1857. He saw active service in the Zulu War of 1879, and retired from the Army in 1888 with the rank of Colonel.

A few years later, on the death of his kinsman, James, he established his claim to the barony, which was created in 1647. He sat in the House of Lords as a Scottish Representative Peer since 1900, and having lost his only son, the Master of Belhaven, in the war, is succeeded by his nephew, Lieutenant-Colonel Robert Edward Archibald Hamilton, C.I.E., Financial Member of the State Council at Jodhpur.

In 1878 Lord Belhaven, then Major Hamilton, joined the Society, and in 1885 he was elected to the Council, a position he continued to fill, with one interval, until 1901. He also served for many years on the Colonial Section Committee. He frequently presided at meetings of the Society, and on numerous other occasions took part in discussions. In view of the present position of motoring, it may be interesting to recall some comments he made when presiding, about twenty years ago, at the reading of a paper on "Cycling: Historical and Practical." He rather complained of the author of the paper for not carrying on his history to the "very last development in which the rider had little or nothing to do except to supply himself with an auxiliary steam engine, on which he sat, and which did his work for him." They did not know, he added, how far such things might be developed; cycles which would run for many hundreds of miles without much assistance from the driver might become very practical things.

An enthusiastic and persistent advocate of the metric system, he once introduced a Bill into the House of Lords providing for the compulsory adoption of that method of measurement after the lapse of four years.

NOTES ON BOOKS.

Examples of Modern Bookbinding. Designed and executed by Robt. Rivière & Son. London: Bernard Quaritch, Ltd.

Examples of Bookbinding Exhibited at the Leipzig Exhibition in 1914. London: Robt. Rivière & Son.

The bindings of the books referred to in the second of these volumes were designed and executed with the special object of being shown at the Leipzig Exhibition in 1914. Unfortunately, after they had been on view for a few weeks the Great War broke out and the exhibition was closed. The exhibitors were naturally extremely anxious as to the fate of their works on which the utmost care had been expended, and it is satisfactory to learn that the books have at last been returned to them none the worse for their experiences.

The illustrations in the first volume are in colour, those in the second are in black and white. Most of them are exceedingly beautiful, and they deserve very careful attention on the part of all interested in a fascinating art. It seems out of place to select particular specimens and attempt to describe them; failing the opportunity of seeing the bindings themselves, the only way to obtain a fair idea of their excellence is to study these illustrations, which are admirably produced. One result of such study is to confirm the writer in his opinion that in work of this description the strictly conventional is the only wear: in his opinion the least successful examples are those in which appear more or less realistic representations of the human body.

GENERAL NOTES.

Leather from Germany.—The Parliamentary Secretary to the Board of Trade, replying to a question in the House of Commons on October 25th, stated that during the first nine months of this year the registered imports of dressed leather consigned from Germany amounted to 4,571 cwts., and of undressed leather to 126 cwts. No leather had been imported by way of reparation or indemnity.

Oil Resources of the United Kingdom.—In the House of Commons on October 27th the Government were asked what steps, if any, are now being taken to discover new sources of oil fuel and oil shales in this country; and whether a definite policy with regard to any oil fuels that may be discovered in the kingdom has yet been arrived at. Mr. Kellaway replied as *follows:* In addition to eleven Government borings in Derbyshire, Staffordshire, and Scotland, three licences have been granted to companies or persons wishing to bore for petroleum. A company is now engaged in developing the oil shale deposits of Norfolk. With regard to the second part of the question, the matter is still under consideration.

International Advertising Exhibition.—This exhibition will be held at the White City from November 29th–December 4th, 1920. The Reception Committee are reserving a number of free invitation tickets for Fellows of the Royal Society of Arts, and those desirous of visiting the Exhibition should apply to the International Advertising Exhibition, Reception Committee, 167, Strand, W.C. 2.

Canada and Emigration.—Some interesting articles contributed to *Canada* by Mr. J. Obed Smith, Superintendent of Emigration for Canada in Europe, have been reprinted in pamphlet form with the title "The Value of an Emigrant." The author mentions *inter alia* that 65 per cent. of the Canadian population were born in the Dominion; that the immigrants during the last twenty years numbered nearly 3,500,000, and that of those who arrived during the year before the war 108,000 were English, 30,700 Scottish, 9,700 Irish, and 2,000 Welsh. In a chapter headed "It will Pay Canada," he points out that the cost of transport is in existing circumstances largely prohibitive for the domestic and other classes chiefly needed by the Dominion, and that the Imperial Government's "war gift" of free transportation ceases at the end of the present year.

Journal of the Royal Society of Arts.

No. 3,547. VOL. LXVIII.

FRIDAY, NOVEMBER 12, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

OPENING OF THE 167th SESSION.

The 167th Session of the Society will be opened on Wednesday, November 17th, at 8 p.m., when an experimental address on "Wireless Telegraphy and Telephony" will be delivered by MR. ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council. It is hoped to show, amongst other things, the automatic printing in ordinary Roman type of wireless messages received in the lecture hall from a distance. This will be the first time that this fresh departure in wireless telegraphy has been exhibited.

ARRANGEMENTS FOR THE SESSION 1920-21.

Particulars of the arrangements for the forthcoming session, so far as they are at present completed, have been posted to all Fellows of the Society. Any Fellows who have not yet received them are requested to communicate with the Secretary.

CANTOR LECTURES.

The Cantor Lectures on "The Decoration and Architecture of Robert Adam and Sir John Soane," by ARTHUR THOMAS BOLTON, F.R.I.B.A., F.S.A., Curator, Soane Museum, have been reprinted from the *Journal*, and the pamphlet (price 2*s*. 6*d*.) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. 2.

A full list of the lectures which have been published separately, and are still on sale, can also be obtained on application.

CASES FOR JOURNALS.

At the request of several Fellows of the Society, cases have been made for keeping the current numbers of the *Journal*. They are in red buckram, and will hold the issues for a complete year. They may be obtained, post free, for 7*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ALUMINIUM AND ITS ALLOYS.

By W. ROSENHAIN, D.Sc., F.R.S.

Lecture II.—Delivered April 19th, 1920.

The brief account of the properties of pure aluminium, given in the previous lecture, suffices to show that for many engineering purposes this metal in its pure state is entirely unsuited. Not only in the cast condition, but also when rolled, and even when hardened by cold rolling it is still too soft and weak for uses where heavy stresses have to be borne. It has accordingly long been the aim of metallurgists interested in aluminium to discover alloys which shall provide the desired strength, toughness, and stiffness. It must be remembered, however, that the feature which primarily makes aluminium attractive from the engineering point of view is its lightness, and it is therefore necessary that any satisfactory alloy shall combine, as far as possible, the desired degree of strength and ductility with a retention of the low specific gravity of the pure metal. With the exception of some special alloys produced by the addition of magnesium to aluminium, all the well-known alloys of aluminium are heavier than the pure metal. The superiority of any alloy over pure aluminium, therefore, depends upon the ratio which the improvement, brought about in the mechanical properties by the addition of other metals, bears to the increase of density which accompanies them. This ratio really determines the value of any alloy from the point of view of combined strength and lightness. The great difficulty in arriving at a numerical value, however, which shall furnish a just basis for comparison and classification of different materials, lies in deciding what typical property or combination of properties is to be regarded as indicative of "strength." In many respects one is accustomed to regard "strength" as merely

equivalent to "tensile strength," and although tensile strength does give a valuable indication of the general typical character of a metal, it must be borne in mind that there are many other forms of stress to which materials are exposed, and that the resistance of a metal to pure tension does not necessarily measure resistance to shear, compression, or alternating stresses. If, however, we accept tests of tensile strength as our guide for the moment, it is possible to express the value of an alloy, from the point of view here under consideration, by a fraction in which the tensile strength per unit area is divided by the weight per unit volume. This ratio, to which I have given the name "Specific Tenacity," may be more precisely defined in the ordinary British units as being equal to the tensile strength in tons per square inch, divided by the weight of one cubic inch of the material in pounds.

Long ago, Galileo hit upon another method of expressing this same ratio. If a rod, bar, or even wire, of a metal is suspended vertically, the upper portion of the piece is exposed to a tensile stress equal to the weight of that part of the metal hanging below it. It follows, therefore, that for every material there is a maximum length whose weight it can just support. This maximum length of its own material, which the metal is able to support, is a measure of the specific tenacity, and the value of an alloy may therefore be expressed in terms of such a length. In actual cases these lengths run into miles, ranging from three to fifteen.

Accepting the fact that it is necessary to improve the mechanical properties of pure aluminium before the metal can be used for many engineering purposes, we may next inquire how that improvement is to be brought about by the addition of other elements. It is readily understood if we glance at the microstructure of pure aluminium, which in many respects is very similar to the microstructure of other pure metals. This has already been illustrated in Fig. 6 of the first lecture. That figure represents the typical structure of a pure metal, which is known to consist of an aggregate of a large number of minute crystals. When a material having such a structure is exposed to severe stress, the crystals themselves undergo deformation by a process of slip which occurs within each of the crystals. If now we wish to strengthen the material, in order to give it increased resistance to stress, there are two methods which are open to us. In the first place, it is possible to stiffen up the crystals themselves by adding to the metal another element, generally also a metal, which remains in the solid material uniformly disseminated throughout the crystals, and exercises its strengthening and stiffening effects within those crystals themselves.

The second method which is open to us is to introduce into the microstructure a second new constituent. Certain elements when added to the pure metal do not remain uniformly disseminated throughout the crystals of that metal, but make their presence felt by the appearance of a second constituent in the interstices and boundaries of the original crystals. The second constituents produced in this way are always harder and stronger, but at the same time more brittle than the crystals of the original metal. When, therefore, the second constituent is present in small amounts, it serves merely as a strengthening and stiffening framework, which locks the crystals together and assists them to resist deformation by stresses applied from outside. This strengthening effect is, however, accompanied by a reduction in ductility, and when the amount of the second constituent becomes large this reduction in ductility becomes serious, and ultimately the alloy becomes brittle. The two types of alloys resulting from additions of metals, producing the two kinds of effects just described, are known as "solid solution" alloys and "duplex" alloys respectively. For the majority of purposes the solid solution alloy in which no second constituent is present has many advantages, particularly because it is possible to add much larger quantities of the alloying element if it remains in the form of a second solution, than if it becomes separated in the form of a second constituent. It is, however, possible to combine the advantages of both, either by using two or more alloying elements, or by using an alloying element which, while present in small amounts, remains in solid solution, yet appears as a second constituent when added in larger quantities.

In the case of aluminium we meet with this difficulty, that there are comparatively few elements which form long series of solid solutions with our metal. A long range of solid solution alloys can be formed with hardly any other metal than zinc; considerably shorter ranges of solid solubility are met with in the case of magnesium, copper, and nickel. On the other hand, in the case of such metals as iron, molybdenum, tungsten, vanadium, and others, the range of solid solubility is practically zero, and a second hard and brittle constituent makes its

appearance almost as soon as one of these metals is added to aluminium.

What has just been said is enough to indicate that in the search for valuable alloys of aluminium, the best guidance is to be derived from a knowledge of the constitution and structure of the various alloy systems in question. This kind of knowledge is now available, to a very large extent, in the form of a series of diagrams known as constitutional diagrams or equilibrium diagrams, which represent in full detail the results of metallographic study. This metallographic knowledge, which is partly derived from a study of heating and cooling curves and partly from a careful and systematic examination of the microstructure of the alloys under various conditions of treatment, was not, however, available to anything like a sufficient extent a few years ago.

When, therefore, the increasing uses of aluminium for war purposes rendered it necessary to extend our investigations, a very large amount of work had to be undertaken in exploring and studying the constitution and structure of alloy systems in which aluminium played a principal part. This had to be extended not only to the comparatively simple systems, consisting of two metals—that is to say, of aluminium and one added metal, but also to the much more complicated and difficult cases of alloys containing three metals—that is to say, aluminium and two added metals, such as zinc and copper, silicon and magnesium, and others. We cannot here go into the method by which the exploration has been carried out, nor yet into a detailed account of the results which have been arrived at. Some of these require for their representation models constructed in three dimensions, because it is not possible to represent the constitution of ternary alloys in a simple plane diagram. All we can do here is to glance briefly at the constitutional diagrams and microstructures of a few typical alloy systems, which are of importance in connection with light alloys, and to see in what manner the mechanical properties of these alloys are correlated with their constitution and structure.

The first example we shall consider is that of the alloys of aluminium with copper alone. These have received attention from investigators a good many years ago, one of the most important papers dealing with the matter having been published by my predecessor at the National Physical Laboratory, now Professor H. C. H. Carpenter, F.R.S., and Professor C. A. Edwards, in the Eighth Report to the Alloys Research Committee. From the present point of view, however, the most important detail of the equilibrium diagram is that representing the range of solid solubility of copper in aluminium. This it has been necessary to redetermine carefully by modern methods, for the purpose of arriving at more exact data than were formerly available or required. This portion of the equilibrium diagram is reproduced in Fig. 9. It will be seen that at a relatively high temperature (536° C.), where solidification is just complete, a solid solution of copper in aluminium can exist which contains when in equilibrium as much as 5 per cent. of copper. This is represented by the point *P* in the diagram. The downward curved line *PQ* in the diagram, however, indicates that the solubility of copper

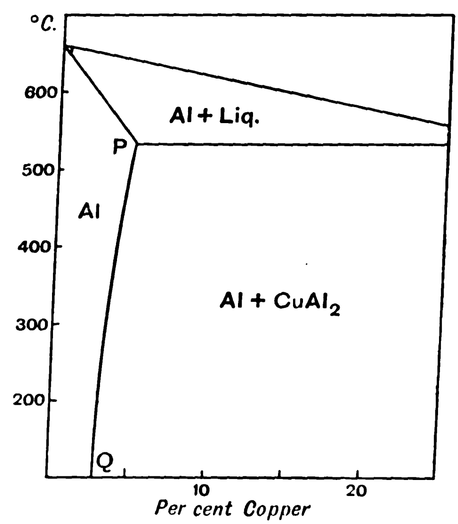

Fig. 9.

in aluminium diminishes with falling temperature, until at the ordinary temperature not much more than 3 per cent. of copper can remain in solid solution. It must be borne in mind, however, that the solid constituent, which separates from these alloys when the range of solid solubility is passed, is not copper, but an aluminium-copper compound $CuAl_2$, a hard but brittle body possessing the characteristic properties of the second constituent referred to above.

The diagram shown in Fig. 9 represents the condition assumed by the alloys when complete equilibrium has been attained. The attainment of complete equilibrium, however, is a matter of considerable time, either during very slow cooling or during prolonged heating at suitable temperatures. As ordinarily cast, the alloys do

not assume even approximately the equilibrium condition, and the result is that the full degree of solid solubility is never attained in alloys prepared under ordinary conditions. As a result, when 2 per cent. of copper is present the cast alloys already show the presence of the second constituent. This is evident in the photomicrographs of these alloys which are shown in Figs. 10 and 11. Fig. 10 represents the structure

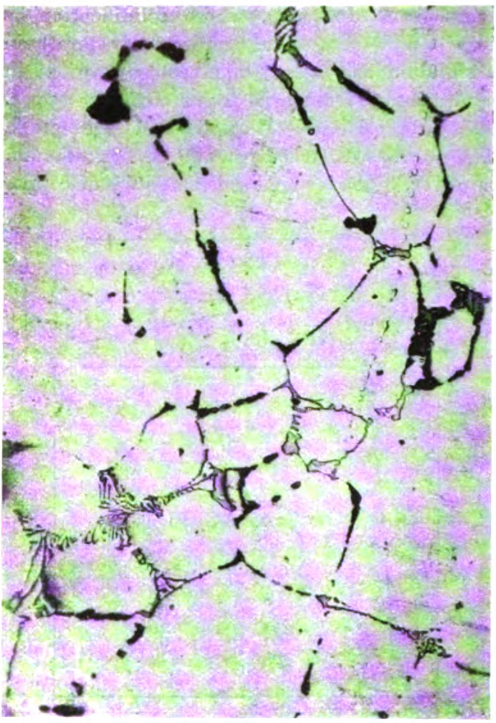

FIG. 10.
ALLOY OF ALUMINIUM CONTAINING 2 PER CENT. COPPER.
Magnification by 150.

of an alloy of aluminium containing 2 per cent. of copper cast in a sand mould, under a magnification of 150 diameters. Fig. 11 shows an alloy containing 3 per cent. of copper when in the form of rolled bars. In both cases, the presence of the second constituent makes itself evident in the dark-etching patches which are visible in the photographs. When larger amounts of copper are added to the alloys, the proportion of this dark-etching, hard, and brittle constituent present in the alloys is very considerably increased. This is clearly indicated in the micrograph, Fig. 12, which represents a section from a chill casting of an alloy containing 12 per cent. of copper, under a magnification of 150 diameters. Here the amount of the dark etching body $CuAl_2$ is very considerable. This particular alloy has been used a great deal, but its value for engineering purposes has probably been very considerably overrated. The mechanical properties corresponding to the alloys, whose constitution and structure we have just discussed, is shown in Table II., which refers to the alloy of aluminium containing 4 per cent. of copper.

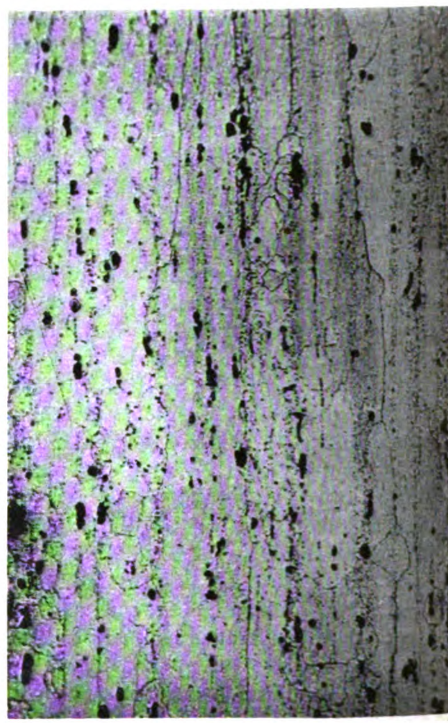

FIG. 11.
ALLOY OF ALUMINIUM CONTAINING 3 PER CENT. COPPER IN THE HOT-ROLLED CONDITION.
Magnification by 150.

TABLE II.—COPPER 4%. ALUMINIUM 96%.

Condition.	Yield stress, tons per square inch.	Maximum stress, tons per square inch.	Extension per cent. on 2 inch.
Sand Cast Rod, 1 inch diameter .	4·9	7·5	5
Chill Cast Rod, 1 inch diameter .	5·4	9·6	10·5
Rolled Rod, ⅞ inch diameter .	11·6	17·0	21
Drawn Rod, ⅞ inch diameter .	18·5	20·0	7·5
Sheet, 18 gauge as rolled	15·9	18·6	4
Sheet, 18 gauge annealed 500° C. .	4·9	11·7	25

It will be seen that in the chill cast condition this alloy attains a maximum stress of 9·6 tons per square inch, coupled with an elongation of 10 per cent. on 2 in. In the rolled condition it reaches a tensile strength of 17 tons per square inch with an elongation of 21 per cent., and by cold drawing the tensile strength can be raised to 20 tons per square inch, but the elongation suffers a corresponding fall. This alloy, it will be seen, represents a very considerable advance on the strength of pure aluminium, but it has been materially improved upon by other materials.

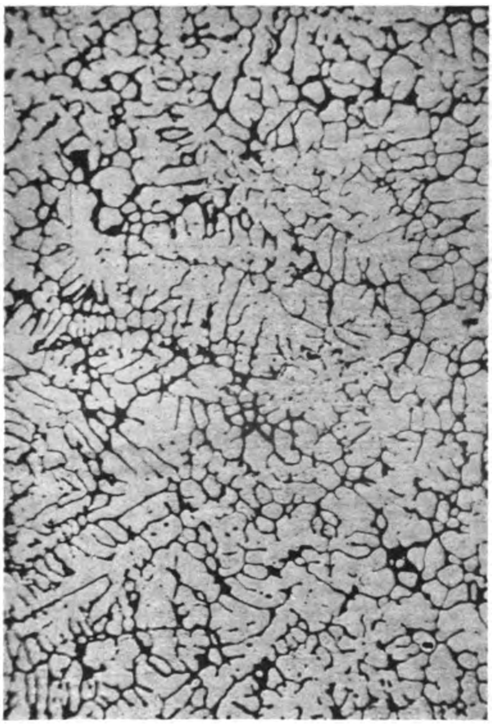

FIG. 12.
ALLOY OF ALUMINIUM WITH 12 PER CENT. COPPER. CHILL CASTING.
Magnification by 150.

The mechanical properties of the alloy containing 12 per cent. of copper, the remainder being aluminium, are shown in Table III.

TABLE III.—COPPER 12% (CAST ALLOY).

	Chill (1 in. diam.)	Sand (1 in. diam.)
Yield stress, tons per sq. in. .	6·4	5·0
Maximum stress, tons per sq. in.	9·7	7·9
Extension, per cent. on 2 in. .	1·5	1

This alloy, of course, cannot be rolled or drawn, so that no comparison is possible with the higher figures of Table II. In the chill cast condition, however, this alloy with a tensile strength of 9·7 tons per square inch shows no advantage whatever over that containing 4 per cent. of copper, while it is appreciably heavier. Further, where the 4 per cent. alloy shows an extension of 10 per cent. on 2 in., coupled with the same tensile strength, the extension in the case of the 12 per cent. copper alloy is down to 1·5 per cent. This agrees well with the much larger amount of the brittle copper compound which is seen in the photo-micrograph.

The alloys of aluminium with copper alone can be slightly improved upon by the addition of a small amount of manganese. If it is not desired further to harden the alloy, the manganese should be used in place of part of the copper. Thus in the 4 per cent. copper alloy, 1 per cent. of copper may be replaced by 1 per cent. of manganese giving an alloy containing, copper 3 per cent., manganese 1 per cent., the remainder being aluminium. The mechanical properties of this alloy are shown in Table IV.

TABLE IV.
COPPER 3%. MANGANESE 1%. ALUMINIUM 96%.

Condition.	Yield stress, tons per square inch.	Maximum stress, tons per square inch.	Extension per cent. on 2 inch.
Sand Cast Rod . .	6·0	7·5	5
Chill Cast Rod . .	7·3	12·1	13
Rolled Rod, ⅞ inch diameter .	12·8	16·5	15

Here the chill casting attains a tensile strength of 12 tons per square inch, coupled with an extension of 13 per cent. on 2 in. This is a very appreciable advance on the figures obtained with 4 per cent. of copper alone. There is also some evidence to show that the alloy containing a small amount of manganese has certain other advantages, particularly in regard to its power of resisting corrosion.

The next group of alloys to be considered are those consisting of aluminium and zinc. Their constitution and properties have been very fully described in the Tenth Report to the Alloys Research Committee of the Institution of Mechanical Engineers by the present lecturer, and Mr. S. L. Archbutt, in 1912. Considering first the constitution of these alloys, the equilibrium diagram is shown in Fig. 13. This diagram is admittedly incomplete in regard to

one or two special points; it shows, however, that a series of solid solutions are formed, containing zinc up to 40 per cent. The alloys which are of any practical importance, so far as light materials are concerned, are those containing less than 30 per cent. of zinc, and in regard to the constitution of these, at all events, there is no room for doubt. When brought into a condition of complete equilibrium, all these alloys show the typical structure of a solid solution closely resembling that of a pure metal. This is shown in the micrograph, Fig. 14, under a magnification of 100 diameters, which represents an alloy containing 15 per cent. of zinc after it has been rolled and annealed. When these which refer respectively to the properties of sand castings, chill castings, and rolled bars ½ in. in diameter, produced by hot rolling.

As regards Fig. 16, referring to sand castings, it will be seen that the ultimate strength increases up to, and slightly beyond, a zinc content of 40 per cent. In the case of chill castings, a first maximum is reached at 30 per cent., and a second higher maximum at 50 per cent. of zinc. In the case of the hot rolled bars ½ in. in diameter, the tensile strength rises up to a zinc content of 26 per cent., this being the limit of the alloys which can be satisfactorily rolled into bars and sheets.

In comparing the tensile strength of different

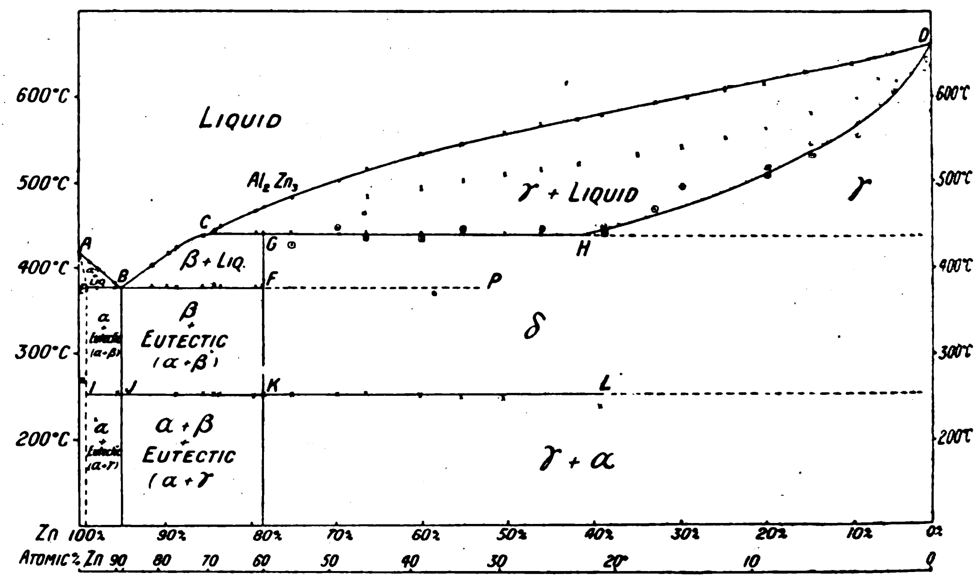

FIG. 13.

alloys are cast, however, they exhibit a markedly different micro-structure, arising from the fact that solid solutions during crystallisation deposit successive layers having different compositions, and these differences of composition are only removed by the process of diffusion which occurs when the alloys are subjected to prolonged heating, and particularly when heating is accompanied by mechanical work. The typical appearance of these alloys in the cast condition, showing the structure known as "cores," is shown in Fig. 15, under a magnification of 100 diameters, which represents an alloy containing 20 per cent. of zinc in the chill cast condition.

The mechanical properties of the alloys of aluminium and zinc, so far as tensile strength is concerned, are shown in Figs. 16, 17, and 18, members of this interesting series of alloys, however, it is important to remember that an increase of zinc content brings with it also a corresponding increase of density. Relative merits of the various alloys, therefore, are to be gauged in terms of their specific tenacity, a term which we have already defined as being measured by the ratio of tensile strength to weight per unit volume. This ratio and its variation with zinc content, in both sand and chill castings, is shown in the graph of Fig. 19. It will be seen that the maximum specific tenacity is reached in the neighbourhood of 25 per cent. of zinc for both sand and chill castings.

The comparison of specific tenacity is, further, of considerable interest, not only as between different members of the same group of alloys.

but also as between the alloys of aluminium with zinc and those of aluminium with copper. This comparison is shown in the diagram, Fig. 20, which relates to rolled bars 1½ in. in diameter. Here it will be seen that the alloy containing 17 per cent. of zinc has a higher specific tenacity than any of the rolled alloys of aluminium with copper alone. With higher zinc content, the specific tenacity of the zinc alloys attain still higher values.

While the mechanical properties of the aluminium-zinc alloys are themselves remarkably promising, further improvement can be obtained by adding to them small percentages of copper, thus obtaining ternary alloys of aluminium with zinc and copper. The complete exploration of a ternary system is a matter of very great difficulty, owing to the enormous number of alloys which it is necessary to examine in order to obtain satisfactory exploration of the whole field of possibilities which such a system presents. In the case of the aluminium-zinc-copper system this exploration has been carried out to a very large extent, but it would occupy too much time and space to reproduce the results in any detail in this lecture. We must, therefore, confine ourselves to one particular example, and this has been shown because of the particular practical interest which attaches to it.

In selecting an alloy out of a series, such as the aluminium-zinc series, in which specific tenacity increases with increasing zinc content, it does not follow that for any and every purpose it is desirable to use the alloy having the highest specific tenacity. It may be found, for instance, that unduly increasing the zinc content brings with it incidental disadvantages, such as difficulties in the foundry and others. Actually, the alloys very rich in zinc have the serious disadvantage that they are very soft and fragile when hot, so that they are very liable to be slightly cracked as the result of shrinkage or insufficiently careful handling. This consideration alone makes it desirable to keep the zinc content of an alloy, intended for extensive practical use, as low as possible. Further, castings particularly cannot be made of less than a

Fig. 14.

Rolled and Annealed.
Magnification by 100.

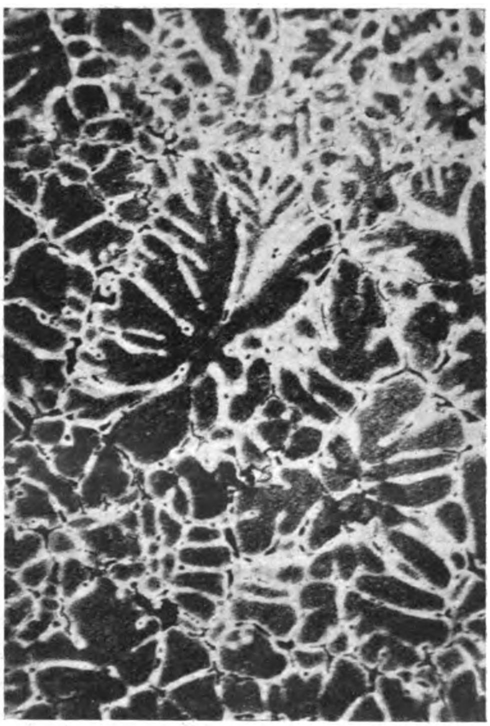

Fig. 15.
Alloy of Aluminium with 20 per cent. Zinc.
Chill Casting.
Magnification by 100.

certain thickness which is necessary to ensure the flow of metal into the various parts of the mould, and also to give the resulting piece sufficient robustness for handling in the workshop and in practical use. The very high specific tenacity of an alloy, however, can only be fully

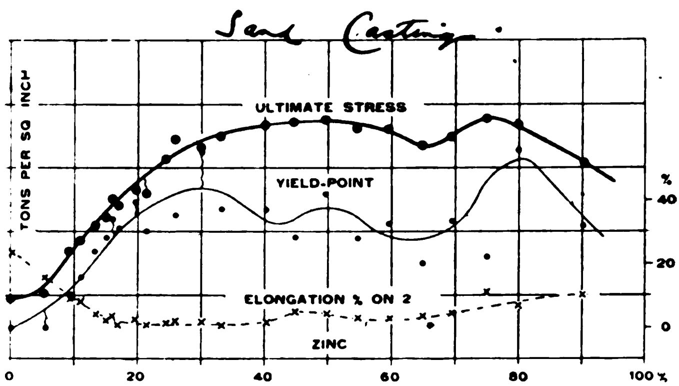

FIG. 16.

utilised if weight can be reduced by reducing thickness. Where the limiting thickness is reached before the specific tenacity is fully utilised, it is preferable to use an alloy of actually lower density, in spite of the fact that its ratio of strength to density may be smaller than that of heavier alloys.

It became necessary during the war to make a selection of this kind in arriving at an alloy to be used generally for castings, which were not intended to be exposed to high temperatures. Examples of such castings are, of course, crank

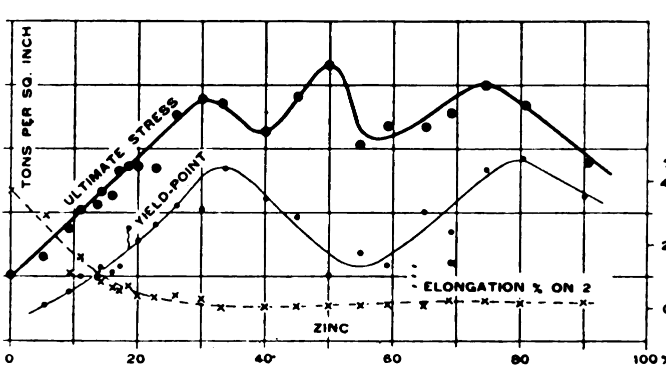

FIG. 17.

cases, and many other parts of internal combustion engines, excluding, however, such objects as pistons or cylinder castings.

The selection arrived at, on the basis of a balance of the best physical properties on the one hand, as compared with the various other considerations indicated above, led to the choice of an alloy containing somewhat less than 15 per cent. of zinc. Advantage, however, was taken of the benefits to be derived from the presence of copper in such an alloy.

The effect of the presence of 3 per cent. of copper in an alloy of this type is indicated in Table V., which shows the yield stress, maximum stress, and extension per cent. on two inches of sand cast and chill cast test pieces from two alloys, one containing 15 per cent. of zinc without any copper, and the other containing 3 per cent. of copper as well as 15 per cent. of zinc. It seems that the presence of the copper brings with it an increase in tensile strength of from two to three tons per square inch.

TABLE V.

	Sand cast.		Chill cast.	
	0 to 15	3 to 15	0 to 15	3 to 15
Yield stress, tons per square inch	9·6	9·8	5·8	7·0
Maximum stress, tons per square inch	11·1	14·4	11·7	13·9
Extension, per cent. on 2 inch	2	3	8·5	6·5

If the addition of zinc is carried somewhat further, a very interesting type of alloy is reached with a zinc content of 20 per cent. and a copper content of 3 per cent. The properties of this alloy in the cast condition, both as cast in sand and in chill, are shown in Table VI., p. 813. Here it will be seen that a tensile strength as high as 17¼ tons per square inch has been obtained. Where light alloy castings are desired, having the highest available tensile strength, there can be no doubt that this alloy offers advantages over the one previously described. It is, however, appreciably heavier and, unless the casting can be made proportionately thinner, advantage cannot be taken of the higher specific tenacity of this material.

The micro-structure of the alloys containing copper as well as zinc, such as the two whose properties have been described above, is interesting because it shows that the addition of copper to these zinc alloys brings about a combination of both the methods of stiffening and hardening a pure metal, which were discussed at the beginning of this lecture. The aluminium-zinc alloys alone are of the nature of simple solid solution—that is, the alloys have been strengthened by a stiffening of the crystals themselves, owing to the presence in them of zinc. The copper, on the other hand, makes its presence felt by the formation of a second constituent, consisting of the aluminium-copper compound Cu Al_2, which appears dark in the photo-micrograph. In the cast alloys, however, the coring of the aluminium-zinc solid solution crystals is very marked, and a complex structure appears under the microscope. This is illustrated in Fig. 21 under a magnification of 150 diameters. After prolonged annealing, particularly if coupled with mechanical work, much of this complexity disappears, and we have either a simple solid solution containing both zinc and copper in the original crystals, or a certain amount of the aluminium-copper compound remains present in the form of dark etching patches scattered among the aluminium-zinc crystals.

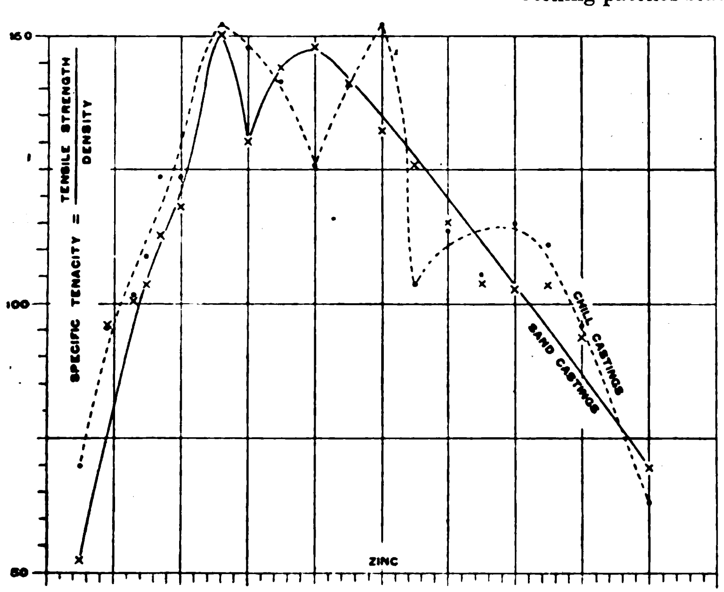

FIG. 19.

The tabulated data concerning the mechanical properties of the alloys containing zinc and copper, which have been given above, indicate that in all cases these alloys in the cast condition possess only a very small amount of ductility. No doubt this arises mainly from the cored structure which exists in the aluminium-zinc crystals, which form the bulk of these alloys. Once this cored structure has been removed, a very much increased ductility is obtained. A constitution of this kind, however, renders an alloy

very difficult to treat mechanically by such operations as forging and rolling. This difficulty exists mainly in the early stages of the operation, when the alloy still retains the comparative brittleness of the cast condition. It was, however, soon found that alloys containing as much as 25 per cent. of zinc and 3 per cent. of copper could be rolled. This was proved by the fact that occasionally a bar of these materials passed through the rolls successfully. So long, however, as experiments on these materials had to be carried out in an industrial plant, no regular success could be obtained. This was no doubt due to the fact that in an industrial plant the rolling conditions must be accepted as they are found. It is not possible as a rule to introduce any material variations in the speed and other characteristics of the rolls available. This consideration, coupled with a full recognition of the very great importance of the part which aluminium alloys were likely to play in the future, particularly in connection with aircraft construction, led to the establishment at the National Physical Laboratory of an experimental rolling mill. This experimental plant is illustrated in the photograph, Fig. 22. The installation consists of an electrically-driven two-high mill, in which flat rolls for rolling sheet metal and grooved rolls for rolling bars and rods can be used interchangeably. The rolls are 2 ft. 6 in. wide and 15 in. diameter.

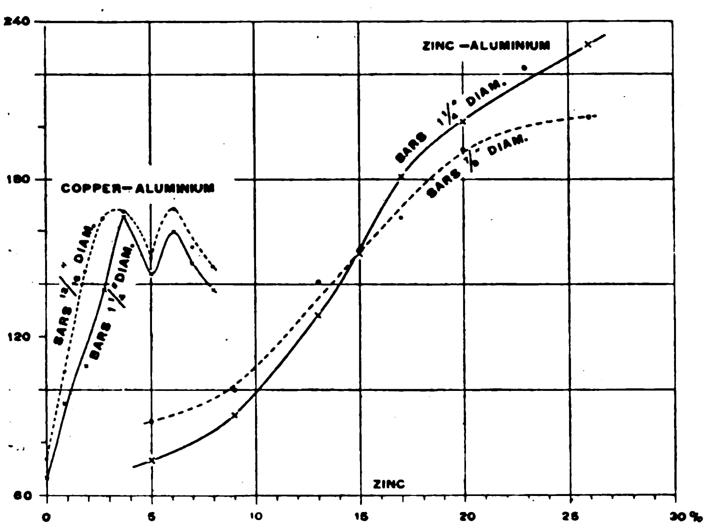

FIG. 20.

Even with this experimental plant, in which all the working conditions were readily controlled by the operator, it did not prove at first at all easy to roll certain of the alloys. Examples of the kind of failures which were obtained in the early efforts are shown in Fig. 23, where it will be seen that the alloys have undergone cracking in a variety of different ways. These difficulties and defects were, however, overcome by a careful study of the conditions under which they occurred. It may be interesting to point out that although many of them could be remedied by suitable adjustment of the conditions of rolling, heating, preliminary forging, etc., the most serious and fundamental difficulties could in nearly every case be traced back to the foundry where the original ingot had been prepared. The extensive experience which has been obtained in this connection, indicates very clearly that a very large percentage of all the defects which are met with in rolled metals generally are traceable to defects in the original cast material as it left the foundry.

As the result of the careful study of the conditions affecting these alloys, both in the foundry, the rolling mill, and in the annealing furnaces, the difficulties have been gradually overcome, and it is now possible to roll a range of materials, which, a few years ago, would have been regarded as quite outside the range of workable alloys. Not only this, but their rolling on a commercial scale has now been carried to such a degree of perfection that the loss by scrap can be kept negligibly small.

The physical properties of the hot-rolled material, as revealed by tensile tests, are shown in Table VII.

TABLE VII.—3 TO 20 ALLOY. TENSILE TESTS.

Condition.	Yield stress, tons per square inch.	Maximum stress, tons per square inch.	Extension, per cent. on 2 inch.
Rolled Rod, 7 to 8 in. diam.	18·8	26·0	20
Sheet, 18 gauge	21·6	26·2	18
	22·1	24·9	17
,, 26 ,,	20·6	27·6	19
	19·1	24·7	18

It will be seen that in this condition the alloys attain a very remarkable degree of strength and ductility, resembling that of mild steel. The tensile strength can be obtained as high as 26 to 27 tons per square inch, combined with an elongation on 2 in. of from 18 to 20 per cent.

The next step in the development of strong and light alloys has consisted in the addition of an element which imparts to them the property of undergoing hardening, which in some degrees resembles that of steel. The element mainly responsible for such a hardening property is magnesium, whose use in this connection was discovered by Wilm in Germany, some ten years ago. He applied it in the first instance to the alloys which were then regarded as the best possible wrought alloys of aluminium, namely, those containing copper and manganese, such as are referred to above. These had first been thoroughly investigated at the National Physical Laboratory here, and an account of them has been published in the Ninth Report to the Alloys Research Committee. The German proprietary alloy "Duralumin" is, therefore, to some extent a direct descendant of the alloys studied here some time previously. The properties of the material obtained by the addition of a small amount of magnesium to the copper-manganese-aluminium alloys referred to, are very remarkable. The material, when hot-rolled in the ordinary way, attains a tensile strength of not much more than 18 tons per square inch. If it is then heated to a temperature a little below 500° C. and quenched in water, its properties immediately afterwards are not very different from those of the annealed material. In the course of a few hours, however, the metal begins to undergo a change in properties. A hardening process occurs which gradually completes itself, at the ordinary temperature, in about four days. This process is represented diagrammatically in Fig. 24, in which Brinell hardness is the ordinate and time the abscissa. Typical properties of duralumin treated in this way are shown in Table VIII.

When the development of the rolled copper-zinc-aluminium alloys had reached the stage indicated above, it was natural to endeavour to effect further improvement by seeking to apply to them the hardening action of magnesium. This has been successfully done, and a series of alloys have been developed at the National Physical Laboratory which attain properties even more remarkable than those of "duralumin." Some additional difficulty in the manipulation of the material is brought about by the introduction of magnesium, but these difficulties have been overcome by careful experimental study. The properties of the resulting material, which has provisionally been called "high tensile" alloy, are shown in Table IX., p. 816.

The alloys have been prepared in various degrees of hardness, and the hardest and strongest of them can attain a tensile strength of 40 tons per square inch. There can be no doubt that these high tensile alloys represent a very considerable advance on the combination of

strength and lightness which has yet been attained in aluminium alloys. That they are likely to find a very considerable degree of useful application appears probable. On the other hand, certain limitations must be recognised. It has, unfortunately, been found that alloys of aluminium containing both zinc and copper are peculiarly liable to corrosion, especially when exposed to contact with sea-water. When kept in the air in the ordinary way, they retain their bright surface almost indefinitely. Immersed in sea-water, however, they rapidly deteriorate. This property must be borne in mind when any attempt is made to put such alloys into practical service. Where they are not exposed to contact with sea-water, and where it is possible to protect them by a suitable coating of varnish or other protective material, no fear of undue corrosion need be entertained. Their physical properties are so remarkable that it is well worth while taking the trouble to ensure adequate protection from corrosion in order to avail ourselves of these materials.

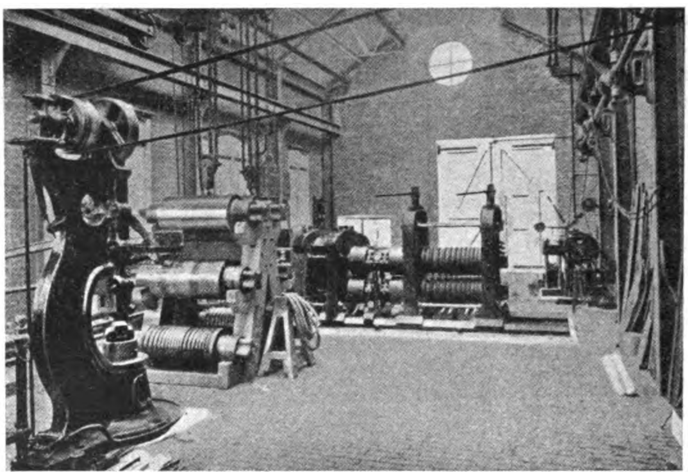

FIG. 22.

In view of the limitations just indicated, an endeavour has been made to find alloys, if possible as strong in proportion to their weight as the "high tensile" series, which shall be free if possible from the tendency towards corrosion, which the former alloys exhibit. Investigation with this end in view led to a study of the alloys in which nickel is present, as well as copper and magnesium. These researches, which were in the first place directed towards the production of a casting alloy having special strength at high temperatures, have led to the development of a type of material which possesses very marked advantages. The tensile strength, even after hardening and ageing, is not as high as that of the "high tensile" series, although it may be hoped that future developments will lead to improvement in that direction. On the other hand, these alloys retain their strength at a higher temperature than any other wrought alloys of *aluminium*, and exhibit a very marked resistance to corrosion, even when in contact with sea-water. Typical of this group of alloys is one containing 4 per cent. of copper, 2 per cent. of nickel, and 1½ per cent. of magnesium, the remainder being aluminium. The properties of this alloy are shown in Table X., but it should be remarked that these figures represent conservative estimates of the results obtainable with this alloy. Since the data given

TABLE X.—4/2/1·5 ALLOY. TENSILE TESTS.

in the above Table were prepared, the alloy has been regularly produced with a tensile strength as high as 27 tons per square inch.

The use of nickel in these alloys offers a point of remarkable interest. Usually it is found that

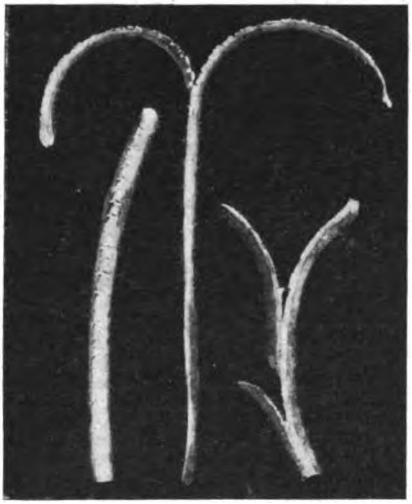

FIG. 23.

the addition of another element to an alloy, already sufficiently hard to be difficult to roll, renders it completely unsuitable for working. The addition of nickel to the copper alloys, however, appears to have precisely the opposite effect. Thus the addition of 2 per cent. of nickel to an alloy already containing 8 per cent. of copper, instead of rendering that alloy harder and more difficult to handle, renders it distinctly easier to roll; in fact, the alloy cannot be rolled in the absence of the nickel, but can be rolled with considerable ease when 2 per cent. of nickel has been added. It would appear that

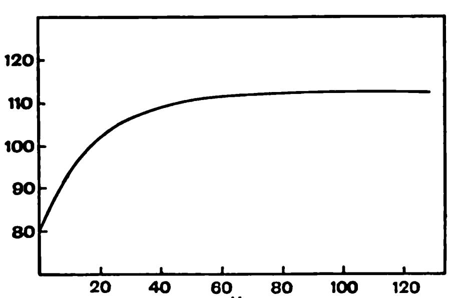

FIG. 24.

this action of nickel is due to the formation of a ternary compound of copper aluminium and nickel, which is less brittle than the binary aluminium-copper compound. This matter, however, is being investigated, and offers very considerable difficulties, so that a definite statement cannot yet be made.

The present lecture may be concluded by a comparison of the various wrought alloys which have been described. Such a comparison is best made in terms of their specific tenacities, and a Table giving the values of their specific tenacities in the ordinary units, and also in terms of miles of lengths of material which can just support their own weight, are given in Table XI.

TABLE XI.

$$\text{Specific Tenacity} = \frac{\text{Max. stress (tons per sq. in.).}}{\text{Weight of 1 cu. inch (lbs.).}}$$

Shaped sand"; for "*Rolled.* Rod 13–16 in. diameter," read "*Rolled.* Rod $\frac{13}{16}$ in. diameter"; and for "*Drawn.* Rod 13–16 in. diameter," read "*Drawn.* Rod $\frac{13}{16}$ in. diameter."]

GENERAL NOTES.

THE NEWCOMEN SOCIETY.—This society has been founded to encourage the study of the history of engineering and technology. Its principal objects are: (1) To disseminate historical information among its members by meetings, intercourse, discussion, correspondence, circulation of notes and papers, and visits to objects and places of interest. (2) To act as a channel of communication between members who are engaged on similar lines of research or study; to indicate, as far as possible, where information is to be found. (3) To collect

and preserve or cause to be preserved, locally or nationally, examples, records, manuscripts, drawings and illustrations of, or relating to, engineering work and industrial processes. (4) To collect and preserve in a similar way biographical matter concerning those men who have contributed to engineering or industrial progress. (5) To publish in a form, and at a date to be determined, a journal containing original memoirs by members and historical material not generally accessible. (6) To form, by collaboration among its members, a card index of published information on the historical aspect of engineering and technology. (7) To do all such acts as shall lead to active corporate life of the society. Further particulars as to membership, etc., can be obtained from the hon. secretary, Mr. H. W. Dickinson, the Science Museum, South Kensington, S.W. 7.

American Commercial Activity.—When H.M. Senior Trade Commissioner in Canada and Newfoundland was in the latter country a few weeks ago, some thirty representatives of American manufacturers were visiting this progressive British possession and only two representatives of United Kingdom manufacturers. "I hope," he writes, "this fact will act as a stimulant, and not as a deterrent, to the United Kingdom manufacturer, as it shows that there must be a great quantity of business to be obtained, otherwise all these men would not be there, and I confidently assert that British goods and British manufacturers will always have the preference." One point that impressed the Commissioner is that many United Kingdom manufacturers insist on treating Newfoundland as part of Canada, instead of realising that it is a separate self-governed territory. These manufacturers try to transact their Newfoundland business through their Canadian agents or houses, a procedure which by no means meets with the approval of Newfoundland buyers, and is the cause of a very considerable loss of business to us.

MEETINGS FOR THE ENSUING WEEK.

Monday, November 15 ... Pottery and Glass Trades' Benevolent Institution, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Dr. M. W. Travers, "Glass in Connection with the Lamp Blown Glass Trade." (Lecture II.)

Botanic Society, Inner Circle, Regent's-park, N.W., 3 p.m. Professor A. W. Bickerton, "The Relations of Astronomy to Botany." (Lecture I.)

Automobile Engineers, Royal Technical College, Glasgow, 7.30 p.m. (Scottish Section.)

Geographical Society, Kensington Gore, W., 5 p.m. Professor H. E. Schwarz, "The Control of Climate by Lakes."

British Architects, Royal Institute of, 9, Conduit-street, W., 8 p.m. Mr. R. Dircks, "The Library of the Royal Institute of British Architects."

Tuesday, November 16...Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.30 p.m. Mr. L. W. Bates, "Colloidal Fuel."

Metals, Institute of (Birmingham Section), Imperial Hotel, Temple-street, Birmingham, 7.30 p.m. Discussion on "Hardness in Non-Ferrous Alloys."

Statistical Society, 9, Adelphi Terrace, W.C., 5.15 p.m. Sir R. Henry Rew, Presidential Address.

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. G. H. Stevenson, "Some New Light on the Franchise Question."

Civil Engineers, Great George-street, S.W., 5.30 p.m. Mr. F. W. Macaulay, "Cross Connections on the Elan Aqueduct of the Birmingham Corporation Waterworks."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 7.30 p.m. Major F. C. Wheeler, "Smoke Abatement and its Remedies from a Decorators' Point of View."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Mr. W. S. Bromhead, "Kenya Colony: its Present Prospects and Future Development."

Electrical Engineers, Institution of (North Midland Section), Hotel Metropole, Leeds, 7 p.m. Mr. C. J. Jewell, "Chairman's Address."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. The Secretary, "Report on the Additions to the Society's Menagerie during the month of October." 2. Dr. W. A. Cunnington, "The Fauna of the African Lakes; a Study in Comparative Limnology, with special reference to Tanganyika." 3. Mr. H. F. Carter, "Descriptions of the Adult, Larval and Pupal Stages of a new Mosquito from Lord Howe Island, South Pacific." 4. Dr. C. L. Boulenger, "Filariid Worms from Mammalia and Birds in the Society's Gardens, 1914-1915."

Wednesday, November 17...Royal Society of Arts, John-street, Adelphi, W.C. 2, 8 p.m. Opening Meeting of the 167th Session. Address by Mr. Alan A. Campbell Swinton, "Wireless Telegraphy and Telephony."

Meteorological Society, 70, Victoria-street, S.W., 8 p.m. 1. Messrs. C. E. P. Brooks and H. W. Braby, "The Clash of the Trades in the Pacific." 2. Dr. W. H. Steavenson, "Note on the Mirage, as observed in Egypt."

Journal of the Royal Society of Arts.

No. 3,548. VOL. LXVIII.

FRIDAY, NOVEMBER 19, 1920.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, NOVEMBER, 24th, at 8 p.m. (Ordinary Meeting). Dr. F. W. EDRIDGE-GREEN, C.B.E., F.R.C.S., Special Examiner in Colour Vision and Eyesight to the Board of Trade, "Colour Vision and Colour Blindness." SIR PHILIP LLOYD-GREAME, K.B.E., M.C., M.P., Parliamentary Secretary to the Board of Trade, in the Chair.

FIRST ORDINARY MEETING.

The Opening Meeting of the 167th Session of the Society was held on Wednesday, November 17th, when an experimental address on "Wireless Telegraphy and Telephony" was delivered by Mr. ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council.

A full report of the meeting will be published in the *Journal* of December 3rd.

ARRANGEMENTS FOR THE SESSION 1920-21.

Particulars of the arrangements for the forthcoming session, so far as they are at present completed, have been posted to all Fellows of the Society. Any Fellows who have not yet received them are requested to communicate with the Secretary.

CASES FOR JOURNALS.

At the request of several Fellows of the Society, cases have been made for keeping the current numbers of the *Journal*. They are in red buckram, and will hold the issues for a complete year. They may be obtained, post free, for 7*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ALUMINIUM AND ITS ALLOYS.

By W. ROSENHAIN, D.Sc., F.R.S.

Lecture III.—Delivered April 26th, 1920.

Having in the previous lecture described the outstanding properties of the more important alloys of aluminium so far as they have been developed, we have now to consider the various uses to which these alloys have been put or can be put. It must be borne in mind at the outset that at the present time aluminium and its alloys must be regarded as relatively expensive material. Their use will therefore be confined to those cases where lightness is of considerable importance, and where the question of cost does not enter so strongly into consideration. This consideration of lightness has undoubtedly been responsible for the very great development which has occurred in the application of aluminium alloys to engineering uses during the war. Their use for all kinds of aircraft naturally occurs to one, but in addition to those uses the alloys have also been employed in very large quantities in automobile construction and also in tanks and in the engines of submarines. While the necessities of war have thus afforded an unprecedented incentive to develop the aluminium alloys and their applications, it should be borne in mind that very extensive fields of usefulness for peaceful industrial purposes also exist. Here the question of price becomes of much greater importance, and the real future of the aluminium industry and of the industry connected with the production of all kinds of aluminium alloys must depend upon a reduction in price of aluminium itself.

The various uses to which aluminium alloys have been and can be put group themselves naturally into two divisions according as castings or wrought material have to be employed in each case. We shall deal first with the question of castings, and these again may be subdivided into two groups—namely, the first group which are used in situations where they are not exposed to high temperatures, and the second group those in which exposure to high temperatures is essential.

In regard to castings of the first group, crank cases for aero engines, automobile engines, and many other purposes, may be taken as an example. Reference to the data given in the second lecture will show that a large number of different alloys are available for such

uses. These include the aluminium-copper, the aluminium-copper-manganese, and the aluminium-zinc-copper alloys. At an early stage of the war, the National Physical Laboratory was asked to advise the Air Ministry, or its then equivalent, as to the choice of the best aluminium alloy for this purpose. In making this choice a number of considerations had to be taken into account. In the first place the highest possible strength was desirable in these castings, but it had to be coupled with reasonable ease of casting and reasonable safety in the manipulation of the casting while hot. In order to obtain the desired strength, it was thought desirable to employ aluminium-copper-zinc alloys, but at the same time it was evident that it would be desirable to keep the density of the alloy as low as possible consistent with adequate strength, since very thin sections could not be used in such castings, and therefore the very high strength of the denser alloys could not be fully utilised.

The specification ultimately suggested was for an alloy containing from 12 to 15 per cent. of zinc and about 2½ per cent. of copper. This is far from being the strongest of the alloys of the zinc-copper aluminium series, but it combines the various properties required in what was believed to be the best possible degree. For the purpose of comparing it with other well-known casting alloys, Table XII. has been drawn up in which the tensile properties of this alloy, which is generally known as "L 5," are compared with those of the alloys containing 12 per cent. and 4 per cent. of copper respectively.

TABLE XII.—ALL TESTS ON 1-INCH DIAM. ROD.

Alloy.	Yield stress, tons per square inch.	Ultimate stress, tons per square inch.	Elongation, per cent. on 2 inches.
Alloy—			
"L 5" sand . .	6·0	9·3	2
Chill	8·2	13·4	5
12 per cent. Copper—			
Sand	5·0	7·9	1
Chill	6·4	9·7	1·5
4 per cent. Copper—			
Sand	4·9	7·5	5
Chill	5·4	9·6	11

When the "L 5" alloy came to be manufactured on a large scale, some peculiarities were met with. It was found that results which had been obtained at the National Physical Laboratory some years ago could not be readily reproduced in the works, and an attempt to reproduce them in the Laboratory also failed at first. It was then discovered that these alloys undergo a gradual ageing process which leads to an improvement in their tensile strength. Tests made on samples some months old therefore give higher results than those made on freshly cast test pieces, and this difference accounted at once for the discrepancies which had been found. The effect of this ageing is an increase generally of the order of two or three tons per square inch in the tensile strength. The ductility of these alloys is so low that any change in that respect can scarcely be traced.

In considering the values of various casting alloys, these ageing effects must be taken into account. In addition, however, some of the alloys are capable of being very considerably improved by heat treatment. Thus the alloy containing 4 per cent. of copper, remainder aluminium, is capable of being very much improved in mechanical properties by a prolonged annealing process. The object of this annealing process is to bring into solid solution as much as possible of the aluminium-copper compound, which in the ordinary cast condition is present in the alloys as a separate constituent. In the case of an ordinary chill cast test piece, this appears to require heating at a temperature from 450° C. to 520° C. for three days. As the result of this treatment, however, the tensile strength of the alloy is increased from 10 tons per square inch to 14·5 tons per square inch, while the elongation per cent. on two inches is increased from 10 per cent. to 20 per cent. This is, of course, a very remarkable improvement, but, unfortunately, heat treatment of so prolonged a period as three days appears to be expensive and may be difficult to apply in practice.

We turn now to consider the second group of castings for which light alloys are required—namely, those which are exposed to high temperatures. Among these, pistons for aero engines, and also for other engines such as those used in tanks and submarines, constitute a most important group. At first sight it would seem that the obvious reason for using aluminium alloy pistons in internal combustion engines lies in the lightness of the metal and the consequent saving in weight of the engine. In the case of very large and heavy engines, such as those of submarines, this no doubt is the main reason for their use, and from this point of view they have proved particularly successful. On the other hand, in aero engines

and in others where it is important to develop a maximum of power with a minimum of weight and petrol consumption, the use of the aluminium alloy pistons is justified from quite a different point of view. In these engines, in fact, the pistons when made of aluminium alloys are frequently made so much thicker in section that no saving in weight as compared with steel pistons is obtained. What is obtained, however, is a very important thermal effect. The thermal conductivity of pure aluminium is of the order of 0·52 as compared with 0·11 of cast iron. The aluminium alloys which are suitable for use as pistons do not quite attain the high thermal conductivity of the pure metal, but many of them attain a value greater than 0·40. Thus the heat-conducting power of an aluminium alloy piston is of the order of four times that of an iron piston of the same dimensions, and if the thickness of the piston can be increased in consequence of the lighter weight of the metal, the heat-conducting power is further augmented. The advantage from the point of view of the high-duty engine lies in the fact that with a piston having this high thermal conductivity, a greater ratio of compression can be used without leading to pre-ignition. The application of this increased compression, together with other subsidiary advantages which are obtained from the use of the aluminium pistons, has led to an economy which, in some engines, has meant an increase of power of the order of 20 per cent. as compared with the same engine working with an iron or steel piston. At the same time an important decrease in petrol consumption per horse-power hour has also been obtained. The importance of such a result from the point of view of aircraft can hardly be overrated, so that some of the disadvantages and troubles which are still met with owing to the imperfections of aluminium alloy pistons, are outweighed by the very substantial advantages which they offer.

In considering the question of the alloy to be used in the construction of an aluminium alloy piston, the temperature to which such pistons are exposed in service becomes a matter of vital importance. Unfortunately it is not easy to obtain exact and reliable data on this point. Some measurements which have been made by Dr. Gibson at the Royal Aircraft Establishment suggested that the maximum temperature does not exceed 250° C.

Some purely metallurgical evidence which has been obtained in my own laboratory tends to confirm this view, as specially prepared specimens of metal inserted in some of these pistons did not show a change of internal structure which would undoubtedly have occurred on exposure to temperatures markedly higher than 250° C. On the other hand, the view is strongly held in some quarters that pistons in aero engines sometimes attain a temperature sufficient to lead to the actual fusion of the aluminium-copper eutectic, and this would indicate a temperature exceeding 530° C. It seems, however, from the nature of the alloys which have been more or less successfully used in such pistons, that the attainment of these temperatures must be exceptional.

A working temperature in the neighbourhood of 250° C., however, represents a set of conditions very different from those applicable to a casting working at the ordinary temperature. The majority of aluminium alloys are found to lose their strength very rapidly with increasing temperature. This is the case to a surprising extent with all the alloys containing any appreciable quantity of zinc, and therefore alloys of that type and of the zinc-copper type must be excluded from use for pistons.

A long series of experiments were carried out at the National Physical Laboratory on the behaviour of various types of aluminium alloys under tensile tests at high temperatures, and these were confirmed by other workers, both at the Royal Aircraft Establishment, Farnborough, and in Professor Lea's laboratory at Birmingham. It would occupy too much space to go into details of all these tests, but in Fig. 25, a series of graphs are given representing the tensile properties at various temperatures of five alloys. These include, in the first place, the "L 5" alloy, containing copper and zinc, which is seen to deteriorate very rapidly with rising temperature. We next have the alloy containing 12 per cent. of copper alone, and also an alloy which has proved very successful, up to a certain point, which has been developed at the Royal Aircraft Establishment. This contains 7 per cent. of copper, 1 per cent. of zinc, and 1 per cent. of tin. All these alloys, in varying degrees, show a decline of tensile strength with rising temperature, although the two high copper alloys do not fall off so rapidly as the alloy containing zinc. The next alloy to be considered is one containing 14 per cent. of copper and 1 per cent. of manganese. This alloy, first developed at the National Physical Laboratory, shows the remarkable property that, up to a temperature of 250° C., the tensile strength of castings increases instead of

decreasing. Unfortunately this alloy proved somewhat difficult to cast, and was regarded as unduly brittle. Development was further hindered by the fact that, in the condition as cast, its thermal conductivity is distinctly lower than that of some of the others. Subsequent work has shown, however, that the reputation of this alloy for brittleness is scarcely well founded, while the thermal conductivity can be brought up to the level of that of the other alloys by a short period of annealing after casting. Some experimental pistons of this alloy have worked quite satisfactorily, and once aluminium founders have learnt to overcome the peculiarities of this material in casting, there is little doubt that it would prove a satisfactory and successful alloy for pistons. The last alloy on the diagram is that containing both copper and nickel (4/2/1½), to which reference has been made in the previous lecture. This alloy shows higher tensile properties at all temperatures up to 250° C. than any of the others, and would therefore appear to be eminently suited for use in pistons. It was unfortunately only developed quite shortly before the close of the war, and therefore its adoption in practice was never carried out. It seems probable, however, that there is a very great future for this particular material, or at all events, for alloys of that type.

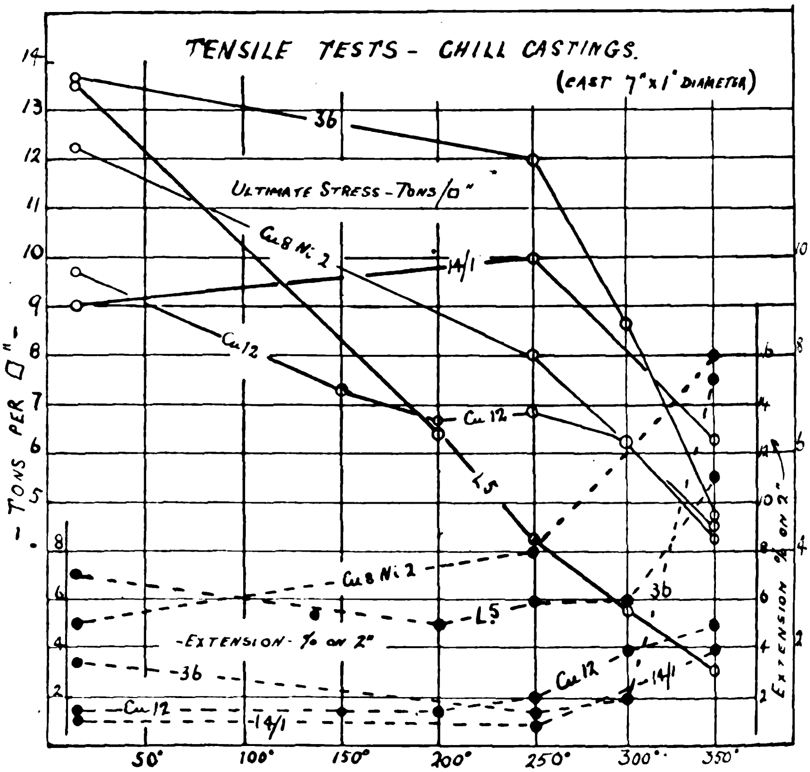

FIG. 25.

Although aluminium pistons on the whole have proved eminently successful in aircraft engines, a certain amount of trouble has been experienced with them. In many cases this is no doubt due to failures of lubrication and similar defects. On the other hand, a whole class of cases of failure have been observed which are grouped under the name of "burning" of pistons. A burnt piston shows a roughened surface which is sometimes deeply eroded, and in some cases, where the defects have gone very far, the piston may be entirely pierced at one point of its head. The exact nature of the action which takes place in these cases has not yet been fully elucidated. In some quarters it is thought that it is simply a question of the local fusion of the aluminium-copper eutectic and its expulsion, followed by the disintegration of the whole metal. If this is the case, the remedy lies in the use of alloys containing a smaller amount of the aluminium-copper compound. A more fundamental explanation seems to be, however, that, since alloys of the 12 per cent. copper type, or of the

type containing 7 per cent. of copper, 1 per cent. of zinc, and 1 per cent. of tin have been so widely used for aero engine pistons, these pistons have been made of alloys not quite strong enough for their purpose at the temperatures to which they are exposed. This argument has been strenuously resisted by those who were anxious to avoid any change in the type of alloy used. There is, however, every hope that the adoption of alloys of the 4/2/1½ type will to a large extent eliminate the trouble from burnt pistons.

A number of other special points have to be considered in regard to the use of aluminium alloy pistons, both in aircraft and in other engines. In the first place it must be borne in mind that the thermal expansion of the aluminium alloys is very much greater than that of iron or steel. The actual comparison is 26 in the case of the aluminium alloys, as compared with 10 in the case of steel. This implies the necessity for a considerably greater amount of clearance between the piston and the cylinder when cold than is necessary where both piston and cylinder are made of iron or steel. This clearance is, of course, taken up when the engine becomes heated, owing to the greater expansion of the aluminium, but it is liable to lead to a certain amount of looseness and noise, due to what is known as "piston-slap," when the engine is first started.

Quite apart from this question of thermal expansion, which is, of course, temporary and reversible when the piston cools down again, a good deal has been said on the subject of the supposed "growth" of aluminium castings when heated and cooled alternately. Such growth is quite a different matter from thermal expansion, since the growth would be irreversible and would lead to a permanent increase in the size of the casting. Careful measurements of this growth in piston castings have been made, and the results of these show that it is a very small matter indeed as compared with thermal expansion. In the case of a casting whose thermal expansion amounted to ·0026 in., the permanent growth amounted to only ·0004 in. In any case, careful previous annealing of the casting will prevent such growth entirely, and it seems that altogether undue importance has been attached to it.

Finally, reference may be made to the question of the manner in which the gudgeon-pin can be made to work in an aluminium alloy piston. In the ordinary practice, steel or iron bushes are provided, and these are cast into the piston casting. This is a fairly satisfactory arrangement, but it has been suggested that the provision of an iron bush is unnecessary, and that it is perfectly satisfactory to allow the gudgeon-pin to work direct in the aluminium casting. Here a great deal must depend upon the character of the casting itself, that is, whether the alloy is strong enough to take the pressure of the gudgeon-pin direct. In the better types of piston alloys now available, this is probably the case. The question of the manner in which an aluminium alloy will act as a bearing metal also arises to some extent, although if the gudgeon-pin is free in the connecting-rod and the piston, the bulk of the movement may be arranged to take place as between the gudgeon-pin and the connecting-rod. Actual experiments on aluminium alloy bearings, however, have shown that these offer considerable promise of satisfactory behaviour, so that from this point of view, also, it may be possible to dispense with iron bushes.

Another type of casting, which is also to some extent exposed to high temperatures, are the cylinder and cylinder blocks of aero engines. In the case of water-cooled engines, these are not exposed to anything like the temperatures which occur in the case of pistons, because the temperature of the cylinder casting is kept low by the circulating water, while the surface in contact with the exploding gases in the engine is generally provided in the shape of a steel liner. In air-cooled engines, however, even although a liner is still provided, the aluminium casting is liable to attain a considerable temperature, and power to withstand that temperature is necessary. In most cases, however, the castings required for cylinder purposes are of a very complicated character, involving a large amount of coring and somewhat difficult casting problems generally. In these circumstances alloys have generally been selected from the point of view of providing the greatest possible facilities to the founder, rather than from the point of view of securing the best possible physical properties for the engine. None the less, from the point of view of saving weight mainly, cylinder castings of aluminium alloys have proved very successful. (A number of examples of such castings, as well as of pistons, and other aluminium alloy products, were kindly lent for exhibition at the lectures by the Birmingham Aluminium Castings Co. and Messrs. Wolseley Motors, Ltd.)

From the thermal point of view, however, the effect of substituting an aluminium alloy casting

for the ordinary cast iron cylinder of an aero engine has been distinctly disappointing. The effect of the aluminium pistons in assisting in the removal of heat from the compression space of the engine having proved so very valuable, it was naturally hoped that similar high thermal conductivity in the cylinder walls would assist to a corresponding extent. Actually this has not been found to occur, and the gain in power and economy from the use of aluminium alloy cylinders has been comparatively small. To some extent this is probably due to the fact that a steel liner is usually interposed between the piston or the cylinder proper and the aluminium casting. The necessity for providing the interior of the cylinder with an iron or steel surface to take the wear of the piston is at the present time universally admitted. An engine has been run in which an aluminium alloy piston worked directly in a cylinder cast in the same material, but it is doubtful whether anyone would care to trust to the reliability of an engine constructed in that manner.

Unfortunately the behaviour of a steel liner inside an aluminium alloy casting is in many ways unsatisfactory. Owing to the fact that the aluminium casting expands much more rapidly with rising temperature than the liner itself, there is a tendency for the casting to expand out of contact with the liner. The result must be the development of a thermal discontinuity between the steel liner and the aluminium casting. This will result in a rise of temperature of the liner which will continue until the increased expansion of the liner, consequent upon such an additional rise of temperature, again brings it into approximate contact with the casting. The engine will therefore run, ultimately, in a condition of equilibrium, in which the temperature of the liner is considerably higher than that of the inner face of the aluminium alloy casting. Were it possible to provide the internal surface of an aluminium alloy cylinder with a hard wearing layer suitable for forming a cylinder wall and taking the wear of the piston, these disadvantages would be overcome. Apart from the question of temperature attained, however, there can be no doubt that the high thermal conductivity of the cylinder castings made in aluminium alloys has proved of considerable advantage in aero engines, particularly in the case of air-cooled engines. In these, when running at high powers, there is a strong tendency for distortion of the cylinders to take place, owing to the fact that the leading side of the cylinder in a rotary engine, or the forward side in a stationary engine, is better cooled by contact with the air than the other side. The result is an unequal expansion and a distortion of the cylinder which leads to bad fitting of the piston. The high conductivity of the aluminium alloy casting, however, equalises the temperature all around the cylinder in a much more satisfactory manner, and enables it to retain its circular section, thus preserving the efficiency of the piston.

Owing to the disappointing thermal results already indicated, aluminium alloy castings for cylinders have not found universal adoption even in aero engines. On the other hand, aluminium alloy cylinder heads have been widely used, and these can be employed without any lining, owing to the fact that they are not exposed to frictional contact with the pistons. Such cylinder heads, however, have to be provided with openings and seatings for the valves, and these again cannot be allowed to work direct on the aluminium alloy. As a rule this has been met by casting into the cylinder head casting suitable rings of steel to serve as valve seatings. In some cases these cast-in pieces have given a certain amount of trouble, but on the whole they can be used satisfactorily.

The question naturally arises whether other engine parts, particularly in aero engines, could not be made of aluminium alloys, and in this connection it is thought that a considerable field for the use of wrought, that is, rolled aluminium alloys may be opened up. In the first place there are a large number of bolts and nuts in all aero engines, and in the aggregate the weight of these bolts and nuts when made in steel is very considerable. Their replacement by "duralumin" or "high tensile" alloys would undoubtedly effect a considerable saving. On the other hand, it must be borne in mind, that, for these purposes, special steels having a very high tensile strength can be used.

A much more interesting but also more difficult problem is the possible use of aluminium alloys for connecting rods. These are exposed to very severe alternating stresses, and at the same time, at one end at all events, they are also exposed to a high temperature. With a view to ascertaining the best alloy for this purpose, a series of alternating stress tests at high temperatures have been carried out. As a result it has been found that the best alloy for such a purpose is undoubtedly the "4 2 1½" type containing copper, nickel and magnesium.

Duralumin is found to come next in order of merit for this purpose, so far as alternating stress tests have indicated. There is, however, considerable difficulty in finding room for somewhat larger connecting rods in many engines, yet such an increase in size is probably essential if wrought aluminium alloys are to be used for that purpose. The development of a light alloy connecting rod for aero engines and possibly for automobile engines generally, is therefore a matter which still lies in the future, although it is a development which is to be anticipated at an early date.

In our discussion of the use of light alloys in aero engine construction, we have already departed from the range of castings and entered the field in which wrought alloys have to be used. This transition has to be made still more completely when we come to consider the material required for structural use in aircraft, both in aeroplanes and the larger and more imposing rigid airships. In the construction of rigid airship frames particularly, there is a large field for the use of wrought aluminium alloys in the form of rolled channels, stampings, and other forms. Hitherto, following the model of the German airships, these have all been made of duralumin. Some of the data now available show, however, that other alloys deserve the most careful consideration for these purposes.

The properties required in the construction of rigid airship girders are obviously the maximum combination of strength with lightness. The form of strength required, however, is not mainly tensile strength, since failure in these complicated structures generally takes place by some form of buckling under a compression stress. (A number of examples of girders from rigid airship construction were exhibited at the lecture, a photograph of one of these is shown in Fig. 26.) The girders of the rigid airship are most liable to fail by buckling under compression, and such buckling may occur either in the girder as a whole, or in any small part of it. In order to ascertain the comparative behaviour of various alloys when rolled into the form of channel sections, such as are used in airship construction and exposed to compression stresses, a series of buckling tests have been carried out, using lengths of 6 in.

The results are given in Table XIII., where it will be seen that the new alloys show very considerable advantages over duralumin. The examples shown (at the meeting) of actual portions of girders constructed of these alloys,

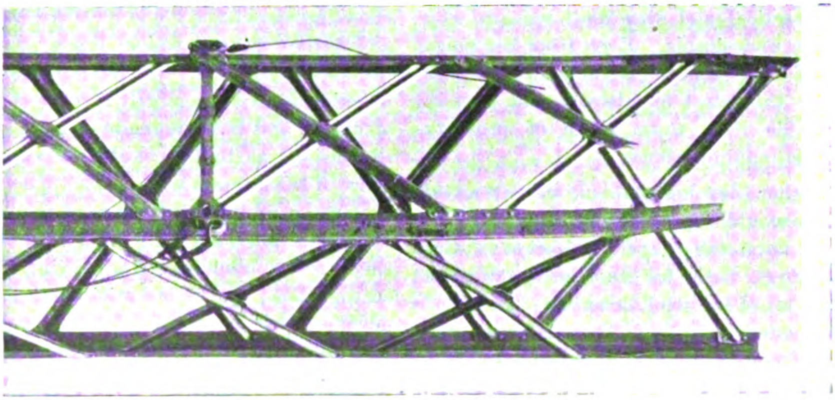

FIG. 26.

TABLE XIII.—COMPRESSION TESTS ON "C" TYPE CHANNELS.

Selected channels ·048 thick.

Six-inch lengths taken and ends "squared off" parallel to each other, and at 90° to C.L. of channel.

Tested with free ends between ball centres at centre of gravity of channel.

Length between ball centres, 7¼ inches.

Area, ·089 square inches.

Alloy.	Load tons.	Buckling stress, tons per square inch.
4/2/1½ alloy	1·171 1·259	13·20 14·16
Duralumin (Vickers)	0·992 1·161	11·15 13·07
3/20 alloy	1·469 1·601	16·50 18·02
H.T. alloy "G"	1·629 1·719	18·31 19·32
H.T. alloy "F"	1·862 2·130	20·97 23·90
H.T. alloy "E"	2·020 2·100	22·72 23·62

are sufficient to prove that the materials are quite capable of being produced and worked up into the condition required for these types of construction.

In the construction of all-metal aeroplane wings also, there is a field for light alloys. At the present moment an effort is being made to prove that high tensile steel can be used with advantage in comparison with aluminium alloys. In view of the fact that the specific tenacities of the aluminium alloys are considerably higher than those of the best steels, this does not appear to be a correct solution. There is a further fact to be remembered, that in the use of a very strong but relatively heavy material like high tensile steel it will be necessary to employ it in extremely thin sections. There are obvious practical and structural reasons why this is very undesirable. Even from the point of view of corrosion, it is doubtful whether these very thin steel members would be any more reliable than those made of properly protected aluminium alloys.

The further development of the all-metal aeroplane would appear, therefore, to be dependent upon the proper utilisation of aluminium alloys, both for the construction of the spars and of the wing covering. The most obvious tendency to be followed in an all-metal construction would seem to be the replacement of the wooden spars and ribs and of the fabric covering by corresponding parts made of aluminium alloys. Considerable success has already been achieved in that direction, light alloy wing spars of strength and reliability at least as great as the best wooden spars have been produced and tested. With regard to the wing covering replacing fabric, it has been found possible at the National Physical Laboratory to roll down some of the strongest aluminium alloys into very thin sheets whose weight per square yard is not greater than that of doped fabric. This very thin sheet has a thickness of the order of ·003 in., and therefore presents considerable difficulty both in course of manufacture and in handling. The actual problem of attachment has been solved by a particular device which allows of the tightening of such metallic fabric by satisfactory mechanical means. There is, however, the very serious difficulty which applies to all sheet metal, that it has no very great resistance to tearing or ripping. In a fabric which is made of distinct fibres, these fibres are able by a mutual displacement to reinforce each other in supporting a tearing effort. In the case of metals, however, no such adjustment is possible, and it is consequently found that any continuous material is liable to tear with relative ease. The relative behaviour of fabrics which are heavily dressed, and in which, therefore, the various fibres are held in position so as to be unable to reinforce one another, and of soft fabrics where the fibres are able to move, in regard to tearing, illustrates what has just been said. The question whether resistance to ripping is of serious importance in aeroplane wings, particularly under peace conditions, where they are not liable to be ripped by flying fragments of projectiles, is a matter to be decided by actual experiment in flight.

As distinct from the tendency just discussed of replacing wooden wing structures by corresponding structures made of metal, there is an alternative course which offers considerable promise of success. In this the actual wing covering is to be regarded as part of the wing structure and is to be made of such shape and dimensions as to be capable of supporting a share of the stresses which come upon the wing. A German all-metal aeroplane of the "Junker" type was provided with comparatively thick sheet metal wing covering having transverse corrugations, but it is anticipated that future developments in all-metal wing constructions will take a somewhat different direction.

Having dealt somewhat extensively with the applications of aluminium alloys to aircraft purposes, it is perhaps desirable to point out that those applications only constitute illustrations of the particular uses of which these alloys are capable, and that there are many possibilities in other directions where the remarkable properties of these materials would also offer very considerable advantages. In all vehicles and appliances, for instance, in which frequent starting and stopping is required, any reduction of weight must be of very considerable advantage. A very large proportion of the power used for our electric railways is expended in accelerating trains on starting, and in stopping them when a station is approached. The enormous amount of power required for these purposes is due to the fact that the actual weight or mass of the train is very large. To a considerable extent this mass is located in the under-frames and wheels of the vehicles, which are ordinarily made of steel or iron. In these parts of rolling stock, therefore, there would appear to be a very considerable field of possible usefulness for light alloys. Experimental work in that direction has been begun,

and it is hoped that in time, as engineers gain increasing confidence in aluminium alloys, their use for purposes of this kind will gradually extend. The use of car wheels made of aluminium alloy castings has already assumed considerable dimensions in America.

Finally, reference may perhaps be made to another possible application of light aluminium alloys in engineering work. In the largest bridges and roofs, it is well known that the greater part of the load which the structure has to bear consists of its own weight, the so-called live load or useful load, such as a railway train, representing only a small fraction of the weight of the structure itself. Actually, the longest possible span which can be constructed is limited by this consideration of the weight of the structure itself and the stresses which it imposes upon its members. The use of a material of very much lower density and of equal strength with mild steel, therefore, suggests the possibility of very greatly increasing the maximum possible span. There are, of course, not many situations in which these very huge spans would be required, but apart from that particular point, it must be borne in mind that the cost of a structure of large span is largely due to the fact that metal has to be provided mainly to bear the weight of the structure itself. It would certainly be possible to reduce this weight to a very considerable extent by replacing steel by aluminium alloys for those parts of the structure, at all events, which are responsible for the greatest development of stress in the remaining members. As an example of what is meant, the central portion of a cantilever bridge may be cited. This is really a small independent girder connecting the ends of the great cantilevers, and it is the weight of this central portion of the span which, to a large extent, governs the size and cost of the cantilevers themselves. By replacing this central span by a structure of aluminium alloy, a very large saving in the weight and cost of the steel constituting the rest of the structure could be effected, and it is, at all events, worth suggesting to bridge designers that the calculation of the relative cost of two structures, one made entirely of steel, and the other in which the central portion was made of a light alloy, is worth considering. Similar considerations also apply to roofs and other structures having exceptionally large span, where the weight of the structure itself enters largely into the cost of the material employed in building it. In the case of roofs, particularly, where the structure is protected from the action of the weather, the question of corrodibility does not enter seriously into the case. In any structure, however, the application of suitable protective coatings would be no more difficult in aluminium alloys than in the case of steel, and in the absence, at all events, of sea water, or spray derived from the sea, the relative permanence of an aluminium alloy structure and a steel structure, both properly protected, would not be very different.

In concluding this necessarily incomplete survey of aluminium and its alloys, and their engineering uses, it is desirable to state that while reference has mainly been made to work done and results obtained in the metallurgical laboratories of the National Physical Laboratory, it is not desired to suggest or to claim that the very great development of aluminium alloys during the years of war has been solely due to the work of that Laboratory. A very large amount of scientific research and experimental work up to a semi-manufacturing scale has been carried out there, and the staff of that department have taken a very active part in the development of light alloys. At the same time a large amount of work has also been done elsewhere, both at the Royal Aircraft Establishment at Farnborough and in various university laboratories, and in a large number of works, particularly in regard to the perfecting of processes of aluminium founding. There has been throughout a very free and helpful interchange of knowledge and experience, and many of the results achieved must be regarded as the product of joint effort.

FOREIGN COMPETITION.

Sir Robert Horne, President of the Board of Trade, was asked in Parliament on November 1st whether he was aware that the larger proportion of the hosiery machinery installed during the war is now standing, and that much unemployment exists in consequence of the enormous import of foreign goods of similar make. Sir R. Horne replied: "I know that unfortunately employment in the hosiery trade is not satisfactory, and that there have been considerable imports of certain descriptions of hosiery in recent months. In so far as these imports are sent here at dumped prices, the matter will be dealt with in the Anti-Dumping Bill which the Government has undertaken to introduce." Another question put to the Minister called for action to protect not only the British hosiery trade, but our lace and fabric glove trades from "dumping."

On the same day the attention of the Government was called to the rapid increase in the imports

of dye-stuffs into this country during the last few months. Mr. Evelyn Cecil asked the President of the Board of Trade whether they come in great part from Germany; and whether, having regard to the experience of the war and the importance of establishing a largely independent British industry of dyes and allied substances on grounds both of trade and national defence, His Majesty's Government would take further steps to safeguard its growth. Sir R. Horne's reply was as follows: "I am aware that the imports of dye-stuffs and intermediates into this country have increased very substantially during the last few months, and that a large proportion of these imports have been from Germany, though I must point out that these include a considerable quantity received from that country under the Reparation Clauses of the Treaty of Versailles. As regards the remainder of the question, I would refer my right hon. friend to the answer which I gave to my hon. friend the Member for Royton on July 20th last, to the effect that in the opinion of the Government, the existence of a strong synthetic dye-making industry is essential to the defence and security of the United Kingdom, and that in pursuance of the pledges given on several occasions, proposals to protect the industry for a time, so as to enable it to be placed on a secure foundation, will be embodied in a Bill relating to key industries, which will be introduced and proceeded with as soon as possible."

On November 9th Sir William Barton (Oldham) asked the President of the Board of Trade whether he was aware that dissatisfaction existed amongst users of colours for cotton textiles at the slow progress made by the British Dyes Corporation, Limited; whether he was aware of reported internal friction and dissensions in the technical directorate; and whether, in view of the national investment in this company, he would say what, if any, control was exercised by the House of Commons. Sir P. Lloyd-Greame replied to the question. He said that the British Dyestuffs Corporation was not at present, and was not likely to be for some considerable time, in a position to produce the whole range of dyestuffs required by the textile industries of this country, but in view of all the obstacles which had to be overcome he did not think there was ground for dissatisfaction with the progress that had been made. There had been some internal difficulties of a character not uncommon in the early stages of a large combination, but he was satisfied that every effort was being made by the directors to remove the difficulties in question. His Majesty's Government had two representatives on the board of directors, with special rights in order to secure the fulfilment of certain provisions of the memorandum and articles of association; but His Majesty's Government had no control beyond that of other shareholders over the internal management of the company.

A table presented to the House of Commons by Sir R. Horne shows that the value of goods, wholly or mainly manufactured, consigned to the United Kingdom from Germany during the nine months ended September 30th, 1920, was £17,190,793. It may be mentioned that the total value of imports from Germany in 1913 of articles wholly or mainly manufactured was £56,143,322.

EFFECTS OF SHORTER WORKING HOURS.*

The reports received from Inspectors show that the shortening of the working hours has had a beneficial effect on the operatives, perhaps more so than any other recent improvement in industrial conditions. The old system of long, dreary, monotonous toil is rapidly giving way to a new system of reasonable hours, so that soon it may be hoped that the overworked man or woman in the industrial world will rarely be found. On all sides workers are securing by their own efforts shorter hours, and many letters are received asking whether periods well within those allowed under the Factory Acts are legal.

Perhaps the classes of workers upon whom shorter hours will have the most beneficial effect will be the growing girl or boy on whom long periods of employment told hardly, and the worker possessing some vision and aspiration towards a fuller life. Regarding the former class the effect of reduced hours and the later morning start is more immediately evident. The pre-war hours of work often entailed very long absences from home—as, for example, in certain cotton districts where young boys and girls residing a long distance from the mills used to leave home before 5 a.m. and did not get back until 7 p.m. They were attracted to the mills by the high wages they could obtain there, and the long day was due to the want of good means of transit between their place of residence and the places where they worked. Now tram and train services frequently fit in better with the new hours, and the shortened day reduces the strain on the growing boy and girl. The gain to married women is also very great as is shown by the eagerness with which the older women in laundries respond to remarks about the shortened hours. It is a relief to them to be enabled to spend long evenings in their homes, and not have the early starts in the mornings.

With regard to the effect of shorter hours on time-keeping and absence from work, although it must be acknowledged that time-keeping depends largely on the character of the individual, and on the organisation, tone and discipline of the factory management, still it is not surprising to hear that better time-keeping has been the result of discontinuing work before breakfast. As far as absence for sickness and other reasons are concerned, there seems no doubt that a shorter working day results in the worker staying out less frequently. In one large factory the average daily absentees numbered some years ago forty; now, with a 44-hour week, the average number of daily absentees has dropped to ten. In a

* Extracted from "Annual Report of the Chief Inspector of Factories and Workshops for the Year 1919."

large laundry the Inspector reports there was a marked improvement in attendance, not only less sickness, but fewer cases of absence for general reasons such as attending to home affairs, the worker being better able to cope with these under the new hours of work.

Some interesting particulars of the reduction of lost time which followed the change to shorter hours at a large engineering works have been furnished. At this factory until last year the hours worked were 6 a.m. to 5 p.m., with 8 to 9 a.m. and 1 to 2 p.m. for meals, making a total of 54 hours. Last year the 47-hour week was adopted—7.30 a.m. to 5 p.m., with one hour for a meal at 12.30. In this factory about 1,200 men and boys were employed before the change, and on the average there were over 800 "quarters" lost weekly. This means that at least 800 workers commenced as late as 9 a.m. instead of 6 a.m. once a week, which was obviously an enormous hindrance to the work of others who came to work in time. In a typical week a few months ago only eighteen half-days were lost by the present staff of 1,500 men and boys. They were allowed grace until 7.40, after which they were shut out until the afternoon. Formerly only two to three minutes' grace was allowed at 6 o'clock, when the late-comers were shut out until 9 a.m.

With regard to the effect on health of the shortened hours, perhaps sufficient time has not yet elapsed for any marked improvement to be noted generally, although the improvement in individuals is evident. Less fatigue and overstrain is found in factories, and one Inspector reports that, although more men are employed in engineering and allied trades, the accident list has not increased, and it is claimed that fatigue is non existent; while another Inspector reports that the manageress of a laundry stated that she noted a perceptible decrease in sickness when she changed from the 8 a.m. to a 9 a.m. start.

It is also perhaps too early to generalise on the effect of the shorter hours in increasing the workers' taste for healthy recreation. It is reported that workers are appreciating the fact that they now have time to work in their allotments and gardens, and to play games or go for country rambles, while the leaders of some social clubs report bigger attendances in all classes, both technical and educational, and say that the members come to the classes fresher and keener than they were in previous years and make steadier advance.

Some occupiers and social workers have realised that the real well-being of the worker cannot be accomplished merely by working shorter hours, although this is a first and essential step as it frees the spirit and leaves some bodily and mental energy at the end of the day for recreation and education. Instead, they realise that the form this education and recreation is to take must be decided largely by the tastes of the workers, as individuals, and that a taste for healthy recreation and for education in varied forms can be encouraged by successful efforts or organisations in these respects in the factory and in outside clubs. Accordingly we have cases reported of successful works schools being carried on in factories, apprentices being allowed one day off a week to attend classes in technical and general instruction, and of firms who encourage outdoor exercises, games and recreations of all kinds. There is still, however, very much to be done in this direction, as the opportunities for wholesome recreation among the industrial classes, especially working girls, is at present very inadequate.

Clearly, the shorter working week brings with it new problems and responsibilities to both employer and worker.

The reports disclose wide differences of experience as to the production of the shorter hours. Frequently it is impossible to make a fair comparison of output before and after the shortening of hours of work, owing to other changes in conditions. Among these changes may be mentioned alterations in machinery or organisation, extensions of work necessitating the employment of much untrained labour, scarcity of workers (particularly of skilled workers), irregular supplies of materials, changes in quality or class of product and in systems of payment.

When the production depends almost entirely on the speed of machinery—as in cotton or woollen spinning—the output is said to be reduced in a proportion nearly, if not fully, corresponding to the reduction in hours. In other machine operations which call for constant alertness on the part of the operator (*e.g.*, weaving) output has not suffered to this extent, and, in exceptional cases, has scarcely been affected at all. In a third class of process, where output is largely or entirely dependent upon the exertion of the worker, there is frequently no loss in production; indeed, in one wholesale tailoring establishment an increase of 40 per cent. is reported (partly due to reorganisation); while in a boot factory, where the hours of work were reduced from fifty-two to forty-eight per week, there was a considerable increase in output. Unfortunately, a few of the reports indicate an extremely unfavourable result in some works, where the shortening of hours has been followed by a reduction in the hourly rate of production, and for this result no adequate explanation has, as a rule, been given.

In order to prevent or to reduce a decline in production, some employers have improved methods of work, and the two following instances may be quoted. One case is that of a silk-spinning and weaving factory, where, although the hours of work were reduced from forty-nine to forty-four per week, the output was increased. Careful records were kept of the output of each machine and worker, and any deficiency in individual output was closely investigated. This frequently brought to light slight defects in machinery which might otherwise have escaped attention, and further disclosed the fact that temperature had a considerable influence on production. It was also found that

some of the workers were not fitted for the work upon which they were engaged, and transference to other duties gave better results. Better methods of training young workers have also been adopted. Further, excellent arrangements have been made for the care of the operatives, including the appointment of a welfare staff and the provision of a rest-room. The second instance refers to the arrangements for cleaning machinery in a cotton-weaving shed containing 1,200 looms. As a rule, this cleaning is done by the weavers, and on Saturday morning the machinery is stopped for this purpose for half-an-hour before the recognised time for ceasing work. In the case in point the weavers do no cleaning whatever. Instead, the occupier has provided ten men cleaners, four being disabled ex-Service men and six elderly ex-weavers. For this service each weaver pays 3*d*. per loom per week, and the arrangement is stated to be highly satisfactory to both parties. The weavers are saved much dirty and uninteresting work, and the looms and shed are in a very much cleaner condition than obtains under the old system. The employer nominally loses £15 per week on this arrangement, but he and the workers are the gainers by a greater output of better quality. Incidentally, the new system removes the temptation to weavers to clean looms while in motion and thus reduces the risk of accident.

GENERAL NOTES.

ZINC ORES IN AUSTRALIA.—It is reported from Hobart that the Electrolytic Zinc Company is continuing its policy of works extension. The proposal is to increase the capacity of the plant at Risdon from 14 tons per day to 100 tons per day, the ultimate outlay on these works being £1,500,000. The ores at present dealt with at Risdon came from Broken Hill, N.S.W. It is believed that when the full plant is installed 50 per cent. of Broken Hill concentrates will be treated within Australia.

MAURITIUS.—At the present time Mauritius is, for its size, one of the wealthiest countries in the world. The prosperity of the sugar industry, according to *United Empire*, is extraordinary, and it is estimated that more than Rs. 200,000,000 will be received for sugar alone during the coming year. Added to the wealth of the last three years, this makes a small community like the inhabitants of Mauritius extremely wealthy. Mauritius planters have unanimously agreed to sell their last sugar crop to Great Britain at a maximum price of £90 per ton, in spite of much higher offers from America and other countries.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 22 ... Pottery and Glass Trades' Benevolent Institution, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. M. W. Travers, "Glass in Connection with the Lamp Blown Glass Trade." (Lecture III.)

British Women's Patriotic League, South Lodge, Rutland Gate, S.W., 3 p.m. Mr. H. Dubery, "The Distribution of the National Wealth."

Aeronautical Engineers, Institute of, Royal College of Science, South Kensington, S.W., 8.30 p.m. Mr. S. T. G. Andrews, "The Education Act of 1918."

Geographical Society, 135, New Bond-street, W., 8.30 p.m. Major F. M. Bailey, "A Visit to Bokhara in 1919."

Electrical Engineers, Institution of (North Midland Section), Mappin Hall, Sheffield, 7.30 p.m. Professor E. H. Crapper, "Permanent Magnets."

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Dr. J. Ph. Vogel, "The Preservation of Ancient Monuments in India."

TUESDAY, NOVEMBER 23...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Botanic Society, Inner Circle, Regent's-park, N.W., 3 p.m. Professor A. W. Bickerton, "The Relations of Astronomy to Botany." (Lecture III.)

Sociological Society, 65, Belgrave-road, Westminster, S.W., 5.15 p.m. Mr. C. R. Enock, "Suggestions towards a Science of Corporate Life."

Anthropological Institute, at the Royal Society, Burlington House, W., 8.30 p.m. (Huxley Memorial Lecture) Dr. A. C. Haddon, "Migrations of Cultures in British New Guinea."

Electrical Engineers, Institution of (North-Western Section), 17, Albert-square, Manchester, 7 p.m. Mr. W. B. Woodhouse, "The Distribution of Electricity."

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. Professor H. H. Dixon and Mr. N. G. Ball, "A Determination of the Heat produced during the Inversion of Sucrose by means of a Differential Calorimeter."

WEDNESDAY, NOVEMBER 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. F. W. Edridge-Green, "Colour Vision and Colour Blindness."

British Academy, at the Royal Society, Burlington House, W., 5 p.m. Professor H. J. C. Grierson, "Lord Byron, Arnold and Swinburne."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Address to the Wireless Section by Dr. W. H. Eccles.

Chemistry, Institute of, University College, Gower-street, W.C., 8 p.m. Mr. J. T. Wood, "Some Scientific Aspects of Tanning."

University of London, Gower-street, W.C., 5.30 p.m. Mr. G. Whale, "The Discovery of Britain."

THURSDAY, NOVEMBER 25 ... Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. 1. Mr. W. B. Woodhouse, "The Distribution of Electricity." 2. Mr. R. O. Kapp, "Some Economic Aspects of E. H. T. Distribution by Underground Cables."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Presidential Address by Mr. E. F. Etchells.

China Society, at the School of Oriental Studies, Finsbury Circus, E.C., 5 p.m. Dr. W. M. M'Govern, "Life in a Buddhist Monastery."

FRIDAY, NOVEMBER 26 ... North-East Coast Institution of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7.30 p.m. Engineer-Commander C. J. Hawkes, "Some Experimental Work in Connection with the Injection and Combustion of Fuel in Diesel Engines."

Electrical Engineers, Institution of (Students' Section), Technical College, Leonard-street, E.C., 6.30 p.m. Mr. A. J. C. Watts, "Electricity and the Paper-Making Industry."

Physical Society, Imperial College of Science, South Kensington, S.W., 7.50 p.m. (Joint Meeting with the Optical Society) "The Making of Reflecting Surfaces."
